In the true science there are no secrets, and no purposes of private gain to serve, but an honourable ambition, an internal satisfaction in communicating those discovered truths to others. It is this which so plainly and broadly distinguishes us from the practitioners of quackery, who, shrouded in the darkness of ignorance, shrink from the shining light which illuminates the object of our search. Our Association has stood pre-eminently forward in the profession in denouncing quackery. At the general meeting held at Brighton last August, the best spirit and feeling prevailed on this subject, and Dr. Cormack, Dr. Tunstall, and Dr. W. H. Ranking, were constituted a Committee to draw up a report on the subject, which they did in the most satisfactory manner, and the proceedings have been printed and circulated among the members.

I will not detain you by denouncing quackery without the profession, unhappily we have too much within it, but that there may be no mistake in reference to the opinions of the members of this Association, and that those practitioners who have lately joined us, and those who have not yet done so, may be thoroughly satisfied. I will read a few of the remarks then made. Dr. Jenks, the president said:—"Such aberrations from the paths of medical science should be abjured and repudiated. As to the apostates themselves, it would be well that by a self-ostracism they quitted together the ranks of a profession which, by a two-faced fellowship, they dishonour and betray." Dr. Cormack said:—"If there be no fear of quackery, in one of its most seductive and demoralising forms, creeping into our Society, to spoil our social meetings, and canker the integrity of our professional intercourse, we need not enter into this discussion; but when we see some members of the medical profession fighting the battles of a mischievous charlatany under the banners of legitimate medicine, it is time to be stirring. To error and imposture there never can be any honourable concession." Professor Dr. Charles J. B. Williams said:—"It might be a question whether it is the province of this Association to take up matters of this kind, and express a decided opinion upon them; but I ask, if we do not take it up where is the body that will? You see all sorts of quackery, with homœopathy foremost, rampant in the land, deluding by its unaccountable infatuations, the powerful, the learned, and the rich. It is a trafficking or gambling with the issues of life and death." Dr. Cowan said:—"With us medical practitioners it is a question of principle, not of doses—a question of morals, not of etiquette. Belief in homœopathy is but the symptom of a mind without stay or ballast, liable to be driven hopelessly into every folly, spurning to-day what was believed yesterday. This is an age of intellectual anomalies. We have amongst us the anomalous paradox of men, educated as members of our honourable profession, adopting and practising homœopathy. These

are dangerous characteristics of an age of over-heated intellectualism, and entering into a consideration of these questions, we are soon hopelessly enrolled in the rapidly-swelling ranks of the deluded and the deluding." Such are the sentiments which have been expressed by these distinguished members of our Association. A series of resolutions were passed, one of which was:—"It is derogatory to the honour of the members of this Association to hold any kind of professional intercourse with homœopathic and hydropathic practitioners." I need scarcely say, that in the resolution as well as in the sentiments expressed, I most cordially agree. A broad line of demarcation must be made. It has been attempted to make this a mere question of doctors differing, and that we ought to give it a trial. A hundred thousandth part of a grain has to be diluted a million times more before it reach the homœopathic tenuity. "And we are to give this a trial. We will not; we disown it, and denounce it as a mockery, a delusion, and a snare. Let knaves profit by hydropathy and homœopathy, and let fools pay for them, whilst, keeping our hands from their pollutions, we cannot but lament that ignorance and credulity have so frequently increased with the accumulation of wealth. In how much more pure an atmosphere we breathe, when we carefully and diligently study the accumulated experience of ages, and then add to it the scientific knowledge of our own times. The shadow of the genius of John Hunter is shed upon us as we tread through the noble apartments of his museum, (the College of Surgeons,) and as we pace its long galleries laden with the treasures of a rifled world, we feel, with pride, it has been given to one amongst us at least, to seize, with sagacious mind, the clue which clear thought and happy opportunity have thrown in his way, and to follow up, link after link, the harmonious chain nature everywhere discovers to her careful observer."*

Let us in our studies emulate so bright an example, and in our practice and intercourse with each other let us be scrupulous to act with honour and courtesy. Our pursuits are liberal, philanthropic, and charitable; we spare not ourselves if the cry of suffering and of pain is heard at our doors by day or by night. There is often a reciprocity of good offices amongst ourselves; let there be one of good feeling also based upon good principle, never trying to raise ourselves by detracting from the merits of others, but rather encouraging amongst each other industry and talent, thus raising and perpetuating the dignity and character of our noble profession. In doing this, whatever division of medical or surgical practice we may choose to take, we shall be prosperous, and happy in the reward of our approving conscience. If clouds have come over us, they will be dispelled as the eastern sunbeams dispel the gloom of the morning; our mid-day life will be satisfied and contented, and when the almond tree shall flourish and the grasshopper shall be a burden, and desire shall fail, or ever the silver cord be loosened, or the golden bowl be broken," old age having crept insensibly upon us, we shall find ourselves tranquil and happy, and possessing that which should accompany old age—"honour, love, obedience, troops of friends."

Mr. A. DARBY, Honorary Secretary, then read the first annual Report, which was as follows:—

Report of the Midland Branch of the Provincial Medical and Surgical Association.

June 3rd, 1852.

On the occasion of our first annual meeting, your Secretaries have the pleasure of reporting that your Councils have not been indifferent to passing events in the medical world; meetings have been held both in Derby and in Nottingham, at which there has been a goodly attendance.

Steps were early taken to increase the number of members by circulars addressed to all the medical men in these two counties.

The principal objects of the Association set forth by circular have been before the members for some time, and although we are not prepared to announce any new matter to the meeting, we feel justified in saying that unity of sentiment has been expressed at the few meetings which have been held, that good feeling has pervaded those meetings, and the hand of friendship has been more closely grasped;—that medical ethics have been considered and discussed in order to develop a rule of conduct for the guidance of medical men, so as to promote the honour of the profession and advance the best interests of mankind. Our preliminary meeting, though not numerous, was marked by an earnest determination to follow up the spirit infused into it by the excellent Chairman and President, Sir Charles Hastings, whose high mental qualifications for such offices were only equalled by the zeal and urbanity with which he discharged them. His qualities of head and heart are worthy to descend to future generations of medical men. Although your association has not hitherto been able to lead the medical mind, it may yet, by the assiduous attention to the important duties devolving upon it, give a bias in the right direction. To this end meetings have been held both in Derby and in Nottingham, in furtherance of the Medical Reform Bill, and it is hoped the other divisions of the Midland Branch will bring their best efforts to bear on the subject, till the cry for Reform, which has sounded in our central counties, shall have echoed through the land. That the theme of Medical Reform should engage our notice in the latter half of the nineteenth century, seems no way strange, seeing that cheap knowledge is increasing,—that the vulgar mind is becoming every day more enlightened,—that the daily struggle to procure a precarious subsistence leads men of no principle to grasp at some of the emoluments and to trespass on the rights of the initiated; gain being their principal object, they think the end justifies the means, and thus quackery rears its head and encroaches on the claims of the unsuspecting members of a proverbially liberal profession, until the medical man is driven to the necessity of making a great personal sacrifice for a future good to his family. Thence we have medical benevolent funds and institutions rising on every hand, from the army medical fund to the College and the fund proposed by the Council of our own Association.

We are happy to find that there are in these midland counties upwards of seventy members of the Association, and we hope to see a considerable increase in a short time.

The expenses of the branch have not exceeded the sum apportioned to it by the general Council of the Association, viz., one-seventh of the income. At the last quarterly meeting held at Derby, the rules of the Manchester Medico-Ethical Association were discussed, and an amended copy sent for approval to the Central Council at Worcester. (An answer has been received from the General Secretary, who has no doubt of their being adopted.)

At the same meeting an instructive paper "On

* *Medical Gazette.*

Epilepsy," was read by Dr. Hitchman, Physician to the Derby Asylum; and a surgical bandage was shown by Mr. Jones, of Derby.

The Rutland practitioners have been invited to this meeting.

Dr. Barclay, of Leicester, has been so kind as to accept the office of Honorary Secretary for Leicestershire; and Mr. Sympton, of Lincoln, has accepted the same office for Lincolnshire.

It is competent for the members to appoint the President-Elect, the Council, the quarterly meetings, and the place of meeting.

In concluding this report the members are informed that Mr. Darby has resigned to Mr. Joseph White, the office of Honorary Secretary for Nottingham.

S. W. FEARN, Secretary, Derby.

A. DARBY, Secretary, Nottingham.

Dr. HEYGATE, of Derby, had great pleasure in moving the adoption of the report. He at the same time was impelled to state the pleasure he felt at seeing so numerous an assemblage in Nottingham, on the occasion of the first anniversary of their branch. He had no hesitation in saying that he did not know a more prosperous Branch Association than this one, and was sure that its founder (Sir Charles Hastings) would be highly delighted when he perused the report, and knew that so many members of the profession had been present at the first annual meeting.

Mr. PAGET, of Leicester, had great pleasure in seconding the adoption of the report, the excellence of which really left him nothing further to say.

The resolution was carried unanimously.

Dr. HUTCHINSON, of Nottingham, said,—I propose that our next meeting be held at Leicester, and that Thomas Paget, Esq., be requested to take the office of President. (Applause.)

Mr. DOUGLAS FOX, of Derby: I have great pleasure in seconding that resolution, and I do so from the knowledge I have of Mr. Paget, the high standing which he has always maintained at Leicester, not only as regards his family, but with regard to his conduct professionally, and in all other respects. I am sure that we shall derive great advantage from having him as our President, and that considerable honour will thereby attach to our Institution. (Hear, hear.) I am confident that every gentleman present will feel that we have made a very good selection, and have therefore the greatest possible pleasure in seconding the motion. (Applause.)

The resolution was put from the chair and carried.

Mr. PAGET: I hardly know how to express my obligations for the honour you have conferred upon me. In reference to the burden you have put upon my shoulders, although I feel I am wanting in many of the qualities which are essential to the proper discharge of my duties, I will endeavour to make up for my deficiencies by steadiness, zeal, and candour, and trust that every indulgence will be shown to me by the Society. (Applause.)

Mr. EATON, of Grantham, briefly submitted the next resolution, which, with the subsequent addition of a name, stood thus:—

"That Mr. Paget, Mr. Macauley, Dr. Shaw, and Mr. Bowmar, be, and are hereby now elected as the Council for Leicestershire."

The resolution was seconded by Mr. FEARN, of Derby, and unanimously affirmed.

Mr. CANTRELL, of Wirksworth: It gives me great pleasure to have the opportunity of proposing the fourth resolution. I have for many years been a member of the Parent Association, and have derived great instruction and pleasure from that connection. I have found the discussion-meetings so useful and agreeable to myself, that I have felt for many years the desire that we should be afforded similar opportunities of uniting nearer home. We, who are engaged in country practice, cannot always attend the meetings when they are held in distant localities, but by having a branch of the Parent Association, we can have our meetings nearer home, and I am sure that it will be very beneficial to us to have such opportunities of communicating to one another the knowledge which we possess, and to become acquainted with men whom we hear of day by day. I propose—"That a Local Council be formed for Lincolnshire, and that Mr. Sympton be requested to make the necessary arrangements."

Mr. BROWNE, of Wymeswold, in seconding the resolution moved by the last speaker, expressed his cordial hope that it would be carried into effect. He would echo the language adopted in the report, wishing that every principal town in the kingdom would form a branch of the Provincial Medical and Surgical Association or Committee. (Applause.)

The resolution was carried unanimously.

Mr. FEARN, of Derby: Before I proceed to read my short paper, I am sure you will excuse me for trespassing for a brief moment by reminding you that another part of our duty still remains unperformed, and that is to thank our excellent President for his admirable, instructive, and lucid address. (Applause.) I beg leave, therefore, to propose that a vote of thanks be presented to our present worthy President for the address he has delivered to us. (Applause.)

Dr. SHAW, of Leicester, in seconding the motion, said there was no doubt that the sentiments enunciated in the address would meet with hearty response from the profession, who would use all the means within their power to promote the objects so ably advocated.

The motion was carried by acclamation.

The PRESIDENT: I thank you cordially for the kind attention you paid to my address, and for echoing the sentiments, propounded, I may say, in all sincerity. I can only say I will do the best I can to conduct your proceedings, and express my hope that every future meeting will be more successful than the one to-day. (Applause.)

Mr. FEARN, then said, I feel very unwilling to trespass at all upon the time of the meeting, and indeed I should not have done so, had I not been pressed to introduce to your notice a little contrivance for the extraction of foreign bodies from the bronchi, which I had the pleasure to exhibit to a few of our members at the close of the last quarterly meeting held at Derby. It will be quite unnecessary for me to detain you long, as all I wish to say is comprised in the recommendation of a *scoop* in the place of *forceps*, for the removal of those substances which most commonly find their way into the air passages. It would be altogether out of place for me to say one word upon the operation of tracheotomy, or to do more than simply remind you of the difficulties often attendant upon the attempt to extract a body lodged in either bronchus. The failure of

such men as the late Mr. Key and Sir Benjamin Brodie in these attempts must be familiar to you all, and it is in the hope that I may furnish you with an additional means of operating successfully that I now request your attention to an instrument which I have myself found available in practice. The *scoop* will, I apprehend, be found most applicable in those cases in which some smooth substance such as a pebble, a fruit stone, a bean, or a shell has been lodged in the bronchus. In such a case as Mr. Liston's, in which a piece of bone was fixed in the right bronchus, we must still trust to the forceps, but I feel a strong persuasion that in all the other recorded cases the scoop would have been found a preferable instrument. The one I have had made is simply a piece of silver eight inches long, with a scoop at each end, (one larger than the other,) and very like the scoop at the end of a director or the old bullet-scoop. I will very briefly relate the instance in which I succeeded. In April, 1848, I was requested by my friend, Mr. Taylor, of Derby, to assist him in a case in which a boy, ten years of age, had let a small cowry-shell slip into the windpipe. The usual distressing symptoms followed, and after in vain attempting to dislodge the substance by inverting the patient, whilst under the influence of chloroform, and striking him repeatedly over the spine, Mr. Taylor made the necessary incisions and opened the windpipe by a slit about an inch long. From the position in which I was placed, and as the risk of suffocation was imminent, the further steps of the operation were assigned to me, and after having several times seized the shell, which was lodged in the left bronchus, but without succeeding in removing it, in consequence of its slipping from the grasp of the forceps, I was enabled at once, and with the greatest facility, to extract it with the scoop of a director. Of course the symptoms were immediately relieved, and under the skilful care of Mr. Taylor, the patient made a speedy and happy recovery.

[The instrument was handed round and examined minutely by the company, whereupon an interesting discussion arose, in which Mr. Paget, Dr. Hutchinson, Mr. Joseph Thompson, Mr. A. Darby, and Mr. D. Fox, took part, all of whom expressed their approval of the instrument.]

Mr. JOSEPH WHITE read a long and exceedingly interesting paper on "The Medical Topography of Nottinghamshire."

Mr. JONES, of Derby, expressed his high sense of the value of the paper to which they had just listened, and moved that the thanks of the meeting be tendered to Mr. White for the same.

Mr. HENRY TAYLOR, of Nottingham, seconded the resolution, and said: Such a paper should not be allowed to pass without due notice being taken of it. It embodied an amount of research, industry, and talent, such as we seldom see displayed. (Applause.) And, if it be not out of place, I would recommend that Mr. White be requested to allow the paper to be printed, as I am well assured that so elaborate and beautiful a composition should not be lost.

The PRESIDENT: I cordially concur in the proposal to have it printed; and I would suggest that we recommend to the Central Council at Worcester that the paper be inserted in their annual "Transactions." (Applause.)

Mr. DOUGLAS FOX, of Derby, supported the resolution. He said: The paper is one I have listened to with the deepest attention. It is highly creditable to the gentleman who has drawn it up, and it is also creditable to the town of Nottingham to contain an individual of such talents and such indefatigable zeal and industry as Mr. White. (Applause) I think it of the highest importance that this paper should be printed and circulated, for the benefit of Nottingham, as well as of other communities.

Dr. HEYGATE: I concur in the suggestion; and I am sure that the Central Council will be but too happy to receive so valuable a document, which must be generally, as well as locally, interesting.

Dr. GILL, of Nottingham, made a few observations relative to a small omission in the paper, while at the same time he paid a high compliment to Mr. White for his truly excellent document, expressing his earnest hope that it might be published.

Dr. SHAW, of Leicester, in the course of a brief speech, said: I listened with more than usual interest and delight to the paper laid before us by Mr. White. I have in former days taken a considerable amount of pains in connection with statistics; and I cannot but pause for a moment to pass an eulogy upon that gentleman for the vast amount of labour which the document must have required; and when we reflect that his time must be almost wholly monopolised at the hospital, we can only be of one opinion,—that he is no ordinary character.

Mr. EDDISON, of Nottingham, having added a meed of praise to Mr. White, the vote of thanks was unanimously carried; the motion including a recommendation to the Central Council at Worcester that the paper be published in the annual "Transactions."

Mr. WHITE having briefly acknowledged the compliment, and expressed his willingness that the paper be printed,

Mr. PAGET, of Leicester, stated that an oversight had most singularly occurred in appointing the Council for the county of Leicester; and to the names of the gentlemen already appointed he proposed that that of Mr. A. Cooper be added.

Seconded and carried *nem. con.*

As the dinner hour was close at hand, it was agreed that Mr. B. W. Brown, of Wymeswold, should adjourn the reading of his paper on "Intestinal Obstructions" to the next quarterly meeting of the branch.

Mr. SYMPSON, of Lincoln, then read a short paper on "Tumour of the Male Breast," which led to a brief discussion.

Mr. EVANS, of Derby, expressed his satisfaction at the success of their meeting, and at the fact that the Branch Association was now established. He begged to submit that a vote of thanks be accorded to their first President, Dr. Bent, to whom they lay under great obligations for his kind and courteous conduct while in the chair, and to whom much of their early success must be attributed. (Applause.)

Dr. HUTCHINSON, of Nottingham, reiterating the expressions of approval, seconded the resolution, which was carried with enthusiasm, and suitably acknowledged by Dr. Bent.

Dr. GOOD was appointed Joint Secretary for Derby

with Mr. Fearn, and accepted the office with sincere pleasure.

Mr. DOUGLAS FOX then moved a vote of thanks to the President for his conduct in the chair, which was carried by acclamation.

Dr. WILLIAMS acknowledged the honour. He hoped that the present might be the worst meeting they would ever have. (Applause.)

At six o'clock in the evening a sumptuous dinner was provided for the members at the George the Fourth Hotel, in Carlton Street. Dr. Williams, the President, occupied the chair, and Mr. Fearn, of Derby, the vice-chair. With one or two exceptions all the gentlemen before named were present, with the addition of W. Felkin, Esq., Mayor of Nottingham; Capt. Legard, President of the Committee of the County Lunatic Asylum; Rev. J. W. Brooks, Vicar of St. Mary's, and President of the Dispensary; W. Hannay, Esq., Chairman of the Nottingham Sanitary Committee; and W. Bishop, Esq.

After the removal of the cloth the PRESIDENT commenced by giving, in succession, the following toasts, all of which were duly honoured:—"Her Majesty the Queen;" "Prince Albert, and the rest of the Royal Family;" "The Church," acknowledged by the Rev. J. W. Brooks; "The Army and Navy," acknowledged by Capt. Legard.

Dr. HEYGATE, of Derby, then proposed, in highly flattering terms, the health of "Sir Charles Hastings, the founder of this Association." This meeting was far superior to the generality of branch meetings, and would not have disgraced the Parent Association itself. The speaker then read a letter from Sir Charles Hastings to Dr. Williams, expressing his regret at not being able to comply with the invitation he had received to attend on this occasion, and saying that he looked forward to no distant day when they might hold the annual meeting of the General Association in Nottingham. He recommended that the matter be talked of by the medical friends at Nottingham, as he considered the town very well situated for the purpose. He was glad to observe they had such an intelligent chief magistrate, and that the Mayor had been asked to be present at the dinner. (Applause.)

The PRESIDENT then briefly, and in complimentary terms, proposed the health of "William Felkin, Esq., the Mayor of Nottingham," which was drunk with applause.

The MAYOR rose to respond, and was received with applause. He expressed his acknowledgments for the kind manner in which his name had been received, and for the honour thereby conferred upon the office he held by the *elite* of a profession of the most important character, of the highest attainment, and of the greatest benefit to society, drawn not only from his own town but from those in the midland district. Both himself and his townsmen held in the highest honor and estimation the gentlemen of that important profession who had associated themselves together, and had chosen Nottingham this day as the place of their gathering. While his townsmen held in high estimation those professional gentlemen who resided in their midst, they hailed with pleasure and satisfaction the advent amongst

them of so many gentlemen distinguished for talent and usefulness from their neighbouring towns. (Applause.) He was assured that their visitors would find in this town gentlemen of the medical profession possessed of talent, assiduity, skilfulness, and of that benevolence of feeling which had ever been the distinguishing characteristics of one of the most useful bodies of the community, in fact, men of that stamp who would bear comparison with those of other towns. (Applause.) He considered that a debt of gratitude was due from society in general to the members of the medical profession which could never be adequately repaid. He was not one of those who begrudged the payment of the medical bills, being convinced that to the gentlemen of this profession they were indebted for many of the comforts, and some of the pleasures of life, and for smoothing their progress to the grave. He could say, for himself and townsmen, that they were increasingly anxious, day after day, to witness the progress of truth and science amongst them; and he only regretted that circumstances had absolutely prevented him from enjoying the opportunity of hearing the remarks and opinions of so many eminent professional men at the previous meeting. He trusted that when their guests came to inquire into the condition of the local medical charities, and into the arrangements which were carried out under the officers of those admirable institutions, they would arrive at the conclusion, that they in this locality were not altogether behind in the march of improvement. After some further remarks, his Worship again tendered his thanks for the kind manner in which they had drunk his health.

The PRESIDENT, before giving the next toast, supplied some explanations in reference to the preparations made for the festivities of the evening, it having been resolved that they should invite, in addition to the members of the medical profession, some gentlemen who were connected with the local charities. They had, therefore, asked the President of the General Hospital, Mr. E. V. P. Burnell; also Captain Legard, the President of the Asylum; the Rev. Mr. Brooks, the President of the Dispensary; the town-member, Mr. Walter; Mr. Nixon, of Nuttal, one of the County Magistrates, and a gentleman who had manifested a gratifying interest in the medical profession, and in the charities of the neighbourhood, an old companion-in-arms; Mr. Oldknow and Mr. Edwin; Mr. Hannay, the Chairman of the Sanitary Committee; and Mr. Bishop. Indisposition and other circumstances had prevented the attendance of some of these gentlemen. The speaker then read letters of apology from Mr. Walter and Mr. Burnell, expressing their deep interest in the progress of the Association; and, after some further observations, highly eulogising the management of the General Hospital, he proposed as the next toast "The Health of the President and success to that Institution,"—(Applause.)—coupling with it the name of the only acting officer present, Mr. Joseph White. (Renewed applause.)

Mr. WHITE, in a brief and appropriate speech, acknowledged the compliment.

The PRESIDENT, (Visiting Physician to the Institution) in proposing "The health of Captain Legard, the President of the County Lunatic Asylum," observed

that many gentlemen had heard him (the Chairman) say what he now with pleasure reiterated, that the medical officers at that institution were supported by the governors in every possible way, and in fact, nearly all the advantages which they had hoped to gain, were now, through the activity, zeal, and kindness of Capt. Legard, likely to be brought before them. The Nottingham Asylum, though one of the worst-built institutions of the kind in England, would, he had no doubt, soon become all that was desired, and very far from the worst in the country, in consequence of the exertions of their truly valuable President. The Chairman then referred to the Benevolent Fund, established by the late Dr. Blake, and the munificent donation presented by Lady Middleton, by means of which they gave the inmates employment and maintenance till they were able to keep themselves. Another great advantage connected with this institution would be the large airing grounds (recently purchased for the manual employment of the lunatics, the humane system being the principle in use at this Asylum. He thought it right to say here, and he did so with all truth and sincerity, that the Nottingham Asylum was the first institution in England in which the humane treatment of lunatics was fairly tried. It was not done suddenly, by taking away from every lunatic in the asylum every fetter and lock at once, but it was progressively done, and in such cases where it was thought it could be done with prudence. Under the care and direction of the late Drs. Drake and Powell, this system was permanently adopted at the Nottingham Asylum. After eulogising the exertions of his colleague—Mr. Alderson, and speaking in terms of praise respecting the general management of the Institution, Dr. Williams concluded by proposing the health of the President of the Nottingham County Lunatic Asylum. (Applause.)

The toast having been drunk with enthusiasm,

Captain LEGARD rose to acknowledge the compliment. After expressing his thanks for the kind manner in which his name had been coupled with the Institution, he explained his own views with reference to what ought to be the treatment of the insane, he being of opinion that the subject was of far more importance than any other, in a medical point of view, inasmuch as every part of the body was useless when the brain was affected. It was lamentable to reflect how much diseases of the brain had been neglected, by being almost universally treated as incurable, while recent experience had abundantly proved that with proper skill and attention, affections of this description might be cured. He trusted that the time was fast approaching when such exertions would be made by the members of the medical profession that insanity would be treated as a disease, in the same way as any other malady; if such were the case, he had no doubt its cure could be reckoned on with equal certainty. (Applause.) He regretted that a sort of disgrace seemed to attach to any member of a family being afflicted with insanity; in consequence of which it was kept a long time secret from the medical profession. They knew from practical experience that it was of the very last importance that cases of insanity should be attended to on the appearance of the very first symptom; that, in fact, the earlier the stage in which it was treated the greater chance there was of

recovery. With respect to the institution for this county, it had been his earnest endeavour to obtain for the patients ample room for the exercise of their muscular energies out of doors, which was one of the principal means for promoting the cure of the disease. It was most difficult to treat the disease if the general system were not kept in a perfectly healthy state. Though they had succeeded in procuring sufficient land to occupy the patients with manual labour, they were still suffering much inconvenience on account of the institution being so very full, and from the number of old patients, whose cure was almost hopeless, but the attention to whom prevented that amount of energy being directed to the younger inmates which would doubtless conduce to their cure. After some further remarks of an extremely useful, but mostly of a local character, the gallant Captain resumed his seat amidst loud applause.

The CHAIRMAN gave as the next toast, "The Nottingham Dispensary," coupling with it the name of the President of that Institution, the Rev. J. W. Brooks, M.A.

Mr. BROOKS having responded,—

Mr. DOUGLAS FOX, of Derby, rose to propose the "Health of Dr. Williams, the President." He discharged this duty because he was not an inhabitant of the town of Nottingham, and also because, as he was an old friend of his, he was anxious to pay his own personal respects to Dr. Williams, and see that all the rest of the company did the same, a proposition which he had no doubt would be received with the cordiality and enthusiasm which it deserved. If they had not known their worthy President before to day, the admirable address which they had heard was sufficient to distinguish him very highly in his profession. Having referred in eulogistic terms to Mr. White's paper, he alluded to the state of medical talent in Nottingham, which was such as to reflect the highest honour and credit upon the midland district. In concluding he expressed his satisfaction at the results of the meeting.

The CHAIRMAN acknowledged the compliment in suitable terms, and shortly after proposed the "Health of the Visitors," Messrs. Bishop and Hannay.

Mr. BISHOP responded to the toast.

The next toast from the chair, was that of "Mr. Paget, the President for the next year," who expressed his acknowledgments. Dr. Heygate proposed "The Health of Dr. Bent, of Derby," after the acknowledgement of which the Vice-President proposed "The Health of Mr. Newnham, of Farnham."

The meeting soon after broke up.

EPIDEMIOLOGICAL SOCIETY.

At the ordinary Meeting of the Society held at the House of the Royal Medical and Chirurgical Society, 53, Berner's Street, on Monday, June 7th, 1852, DR. BABINGTON, President, in the Chair, two very excellent and interesting papers were read on the important subject of Small-pox and Vaccination in India.

The first paper "On the Introduction and Progress of Vaccination into Bengal," by Dr. C. FINCH, late of

the H.E.I.C.S., and Presidency Surgeon, Calcutta, was read by that gentleman, of which we give an abstract.

On the Introduction and Progress of Vaccination into Bengal.

This paper is an epitome of the History of the Introduction and Progress of Vaccination into Bengal," compiled principally from the reports successively published by the Superintendents-General of Vaccination, in Bengal—Messrs. Shoolbred, Cameron, and Stewart.

The periods intervening between the dates of publication, comprise so many epochs in the history of this very interesting subject, beginning with the first notice nearly half a century ago, in 1804, by Dr. Shoolbred, continuing to the year 1829, the date of Mr. Cameron's report, and to that of 1843-44, when Dr. Stewart, the present Superintendent-General of Vaccination, presented his first report to the Government of Bengal. A late and second report, published by Dr. Stewart, has furnished the author of the paper with materials for adding a supplement, which brings down the account of vaccination in Bengal to the year 1850.

The history of vaccination in Bengal furnishes reasons rather for painful commentary than for hearty congratulation on the introduction to our eastern possessions of the greatest boon which science has yet conferred on mankind, and for deep regret that a boon above all price, should have been virtually rejected by our Indian fellow-subjects, through ignorance and prejudice.

Vaccination may be said to have been virtually rejected by the inhabitants of Bengal as a community, notwithstanding the desire and endeavours of the present rulers of India to introduce this inestimable blessing into the countries subject to their rule, placing it within every man's reach, notwithstanding the unwearied zeal and exertions of their medical officers to carry out the purpose of their directors, and notwithstanding the advantages of accepting it being so obvious, and the dangers incident to its rejection so appalling. Half a century has nearly elapsed since its first introduction, and still we hear of severe and fatal visitations of epidemic small-pox causing as much havoc in Calcutta as it does in any unprotected population or community.

It does not appear that the natives of Bengal could have had any disinclination to adopt inoculation, which seems to have been practised from time immemorial, though the worship of the Goddess Situla, who specially presides over small-pox, is general in Bengal, and some of her devotees are so bigoted that they refuse the protection of inoculation until one of their families falls a victim to variola, when they imagine the Divinity is propitiated by the sacrifice.

Inoculation seems the universal practice throughout Bengal and the provinces subordinate to it, and is one of the chief obstacles to the reception of vaccination. Dr. Finch mentions several obstacles to the successful introduction of vaccination in India, among them the chief are:—1. The dislike of the Hindoos to any innovation. 2. Their apathy or indifference to distant danger. 3. The practice of inoculation for small-pox.

4. Climate, which for one half of the year is unfavourable to vaccination. 5. Want of confidence in its protective powers. This last objection being of the latest origin, and of most obstinate tendency.

A retrospective view of the introduction of vaccination does not offer any very immediate prospect of its general adoption by the natives of Bengal.

The second paper read was written by H. L. Stewart, Esq., Assistant-Surgeon Bombay Army.

Foreign Department.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

Induced Abortion.

THE time of this Academy has for several meetings been occupied with the discussion of a question of great importance, though one which, in this country at least, has long been definitively settled, viz., the propriety, medical and moral, of inducing abortion for the purpose of saving the life or health of the mother. In France, as in all countries under the dominion of the Romish religion, the death of the fœtus has been hitherto sternly opposed, as contrary to the dictates of religion; and it has been proposed that the life of the mother should be perilled to the last degree, rather than destroy the product of conception in any period of its development. It is to be taken as an earnest of a more enlightened epoch in French obstetrics, when the opinions of M. Cazeaux, who originated the discussion, can find favor.

The conclusions which this gentleman gave as a *resumé* to a long and interesting paper, may be given as the text upon which the debate arose. These are:—

1. It is only by a false interpretation of divine and human laws, that criminal abortion, and abortion induced under medical supervision, can be regarded in the same light.

2. The intention of the law is to punish criminally; it cannot, therefore, with justice, arraign an act dictated by the purest and most humane motives.

3. If, unfortunately, the choice has to be made between the life of a mother and that of her unborn offspring, the former has, undoubtedly, the stronger claim, and the child ought to be sacrificed, to the salvation of the mother.

4. As induced abortion is a far less dangerous process as regards the mother than embryotomy at full term, the accoucheur ought to give it the preference.

5. Distortions and narrowing of the pelvis beyond a certain point, insurmountable hæmorrhages, tumours of various kinds which impede parturition, but do not admit of removal, are the sole indications for the induction of abortion.

6. The operation should never be performed without consultation.

The speakers who took part in the discussion, of

which we proceed to give a brief abstract, were, MM. Dubois, Danyau, Begin, Chailly, Velpeau, Moreau, Adelon, and Cazeaux. It will be interesting to contrast the opinions of these representatives of the French school of midwifery with those which prevail in our own country.

M. DANYAU, who opened the debate, agreed entirely with M. Cazeaux as far as he went, the only point in which he criticised him was for not including rebellious vomiting among the indications for causing abortion. He controverted, in succession, the arguments of M. Cazeaux against the admission of this indication, which were, that these vomitings were seldom fatal, and often ceased spontaneously, and that it was impossible to judge when the time had arrived at which nothing was to be hoped from other measures. He detailed numerous cases in which death had occurred from vomiting alone, as well as others in which the woman had, under similar circumstances, been rescued from an apparently hopeless state by abortion, and concluded by affirming, that in his opinion abortion or artificial delivery should be undertaken in every instance in which life is perilled by the urgency of vomiting.

M. BEGIN took an entirely opposite view of the question, and rested his arguments upon the moral, social, and religious views, which he brought forward with eloquence, but, as was thought, with a very unscientific bigotry. He pronounced abortion to be murder, and preferred that a deformed woman should submit to the Cæsarean operation, although the mortality of that operation was so frightful. He also severely reprimanded the parents of deformed girls for allowing them to marry, forgetting that when of age they were free agents, and might become mothers without the consent of their relatives, to say nothing of their chances of illegitimate pregnancy.

M. CHAILLY confined himself to the refutation of the opinion that the Cæsarean operation, though it had proved inevitably fatal in Paris, had frequently succeeded in the provinces, and declared in favour of inducing abortion.

M. VELPEAU reminded the audience that he was the first in France to propound the opinion, that when extreme pelvic distortion rendered delivery impossible, abortion should be induced at a convenient period, in preference to having recourse ultimately to the Cæsarean section, and declared that his further experience had in nowise changed his views. He criticised severely the quasi-religious objections to the operation, and put it to the conscience of all, which had more claims to the consideration, the woman who had so many holds upon society, or a half-developed being who had none. He ridiculed the idea that females, with distorted pelves, should or could, justifiably with their other duties, avoid the chances of pregnancy.

The discussion was continued by M. DUBOIS, who took the ground of abortion induced on account of urgent vomiting. In support of M. Danyau, he adduced several fatal cases of this nature, after which he made some observations on the pathology of this severe vomiting. Some, he remarked, considered it

as a mere sympathetic disturbance reflected from the uterus; others, as Siebold, attributed it to actual inflammation of the stomach; others, again, as the result of inflammation of the ovum. He observed that if it were proved that the symptoms depended upon organic lesion of the stomach or brain, no advantage was to be expected from emptying the uterus; but in his own case, and in those of M. Danyau, no pathological appearance could be detected, and death was clearly to be attributed to the reflex disturbance. In such cases he considered abortion the remedy. In proof of this he cited cases in which obstinate vomiting subsided upon the spontaneous death and expulsion of the foetus; and one in particular, in which the improvement was coincident with the moment at which the mother ceased to feel the motions of the child, which was expelled dead two days after. His actual experience in inducing abortion, for the purpose of quelling otherwise insurmountable vomiting, was confined to four cases. In one of these only was life preserved; but the unfavourable result of the others was easily to be accounted for by the extreme prostration to which the patient had been reduced by the vomiting.

On the question so important, as to the period at which abortion should be induced, so as not, on the one hand, to risk an unnecessary interference, or, on the other, to allow of fatal debility, M. Dubois remarks that he would, in the first place, never advise the operation when the prostration had become so excessive as to preclude a chance of rallying under any circumstances, with continued headache, blindness, and approach to coma. On the other hand, he would not have it performed when it could be ascertained that some portion of food was retained, and emaciation did not rapidly progress, and no febrile action had ensued. In either case the operation would be compromised: in the first by being performed when there was no prospect of saving the patient, in the other by destroying a pregnancy which might have been safely conducted to its natural termination. The circumstances which best warrant interference are, in his opinion, these:—1. Vomiting incessant, so that not only aliment but even pure water is infallibly rejected. 2. Feebleness and emaciation, confining the patient to bed. 3. Marked alteration in the features. 4. Febrile reaction. 5. Excessive acidity of the breath. 7. Inefficiency of all other measures.

In reply, M. CAZEUX reiterated his conviction that abortion should not be induced for obstinate vomiting, and thought that the cases of M. Dubois were in his favour, as three out of the four died, and the number of successful cases at present known amounted only to seven. Waiting would, he thought, give better results.

[It thus appears that a marked change has come over French accoucheurs in reference to the question of inducing abortion; and that as in Protestant countries, they are beginning to think it less culpable to destroy an immature life than to risk the existence of a responsible and valuable mother by the ultimate resort to an operation so fatal as that of the Cæsarean section. Two

only of the numerous speakers said anything in favour of the narrow and mischievous opinion inculcated by the Church of Rome, and these were received with unmistakeable indications that they were considered behind the age.]

Correspondence.

THE MEDICAL BENEVOLENT COLLEGE.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Although I am very unwilling to intrude myself upon the notice of my professional brethren, yet as it has been intimated to me, that at the present moment, the interests of what I know to be a most admirable Institution—the Medical Benevolent College—might be promoted by a brief exposition of its claims to professional and general support, I have felt that, in such a cause, no personal scruples ought to be allowed to prevail. With this conviction, I have undertaken to submit a few considerations to the notice of your readers. But, before doing this, it is but due to those whose support it is desired to conciliate, to state that I have not ventured to make this appeal without having deliberately investigated the principles upon which this benevolent institution is based, the objects proposed to be carried out, and the means by which they are to be realised. The pressure of many engagements, joined, I may add, to the desire of watching the development of the plan when first submitted to the profession, for some time prevented me taking any active part in the preliminary proceedings. Latterly, I have, as a member of the Council, personally participated in the deliberations of that body, and I have thus acquired a full and complete insight into what it is no misnomer to style a “national undertaking.” The principal, and, as I would respectfully submit, the sufficient claim which may be urged on behalf of this Benevolent College to the general support of the profession, is the comprehensiveness of its character. It secures all the objects that the most enlarged philanthropy could suggest, or that the most varied wants could require. It provides a home for the widow, a retreat for the less fortunate of our professional brethren, and a boon, inestimable—a sound, superior education, for the sons of duly qualified medical practitioners, at a cost so very moderate as to place it within the reach of the great body of the profession. It had been the intention, as I am informed, of the gentleman to whom the high merit of originating and vigorously advancing this great scheme is due, (Mr. Probert,) to provide annuities for the solace of those needing them in declining years—a point which was only abandoned on the consideration that such a procedure might seem to trench on the operations of another most admirable institution. But, although for the present no direct pecuniary aid is contemplated, such assistance will indirectly, and in its

best form, be administered by the admission of a certain number of “Foundation Scholars,” who will be entirely educated, clothed, and maintained by the College; nor will the elderly inmates be overlooked, inasmuch as the laws give to the Council a discretionary power of making money contributions to the “residents,” according to the state of the funds. The Medical Benevolent College affords, in its several departments, a most suitable opportunity, both to individuals and to societies, to secure the advantages just enumerated to those members of the profession to whom they would be a welcome boon, since the Council have the power of granting to parties, upon the payment of a certain sum, the right of nominating “residents” and “scholars.” When the Institution shall be in actual operation, there can be no doubt that many benevolent individuals, actuated by friendship and philanthropy, will avail themselves of this provision; and at the present time several local medical societies are, with that object, contemplating the presentation of considerable sums to the funds of the College, in order to expedite its erection.

An Institution, embracing so many admirable objects, appears to merit the combined and active support of all classes of medical men. Our professional brethren may aid in this goodly work of beneficence, not only by pecuniary contributions, but also by acting in all parts of the country as “local secretaries and treasurers.” It is not too much to affirm that a deep debt is due to the profession from the public. There is in this community no class which renders so many and such important unpaid services; and is there a family in this kingdom that does not feel they have, perhaps under the most distressing and delicate circumstances, received from their medical attendants benefits which no money could repay? In the midst of pestilence, again, the practitioner of medicine is ever at his post; and how many are the heroes who, in administering to the victims of fever and of cholera, have laid down their own lives an offering to the sufferings of humanity. Many noblemen, prelates, and other distinguished individuals, have already contributed to the funds of the Benevolent College; and doubtless their number might be greatly increased by active and judicious exertions.

In conclusion, I would remark, that the success of this Institution may be regarded as secured; the large sum of nearly £10,000 has been obtained, £1,000 of which are annual subscriptions, and mainly owing to the exertions of one individual. A most eligible site for the requisite building is about being conveyed to the Trustees. A plan combining all the most important improvements in construction, has been submitted by the architect; and a most zealous and intelligent Council, after having prepared an excellent code of laws, will watch over the progress and prosperity of the College. In order speedily and fully to realise the great objects contemplated, all that is now required is an earnest and combined effort on the part of all ranks of the profession. And when it is recollected that, in addition to its other philanthropic objects, this is also

the cause of the widow and orphan, we may, in humble reliance on the Divine blessing, confidently anticipate a happy and triumphant result.

I am, Sir, your obedient servant,

R. D. GRAINGER.

Highgate, June 2, 1852.

Medical Intelligence.

DEATH OF DR. ROCHOUX.

This able physician, well known to English readers by his writings on apoplexy, has recently died at the age of 67. His last appointment was that of physician to the Bicetre, where he resided fifteen years. Latterly he lived in the country, and only came to Paris to attend the Academies and visit his friends. He had never any great amount of practice in Paris; but in early life he was a successful practitioner in Guadeloupe, and returned with a small competency, the result of his labours. He died of stone in the bladder, with its complications of cystitis and prostatic disease, for which he was for a long time under the care of Civiale. He was an admirer of the Epicurean philosophy, of which he, at least, offered a favourable specimen, for he "placed his delight in moderation and honesty with the cultivation of science and philosophy." So says his biographer.

THE ADULTERATION OF BITTER BEER.

[The following letter has been sent to Mr. Allsopp by Liebig, and will satisfy any remaining doubts as to the purity of an article which is now so generally recommended by the profession, that we are bound to consider whether that recommendation is founded in truth. That it is so, there can now be no doubt whatever.—Ed. J.]

The unguarded remark of a French chemist, that the strychnine imported into England, is employed in part as a substitute for hops in the manufacture of beer, has lately spread alarm among the lovers of pale ale. Having been appealed to by you to express my opinion on this subject, which appears to me to be, in a dietic point of view, one of considerable public interest, I now offer the following brief statement:—

About a quarter of a century ago, a brewer in Westphalia fell into the practice of adulterating his beer with *nux vomica*, from which it is well known that strychnine is obtained. The peculiar morbid symptoms, however, which resulted from the consumption of this adulterated beer, speedily led to the detection of the fraud. The effects produced by *nux vomica* and strychnine are so characteristic, that every medical man will readily detect their origin. The French novelist, Alexandre Dumas, has described them, though with more imagination than truth, in his romance of "Monte Christo." It is possible that the Westphalian case, which from being made the subject of a criminal trial

obtained great notoriety, has given rise to the assumption that in England the strychnine imported is used for the purpose of mixing with beer. But nobody, at all acquainted with the great breweries of that country, could seriously entertain the suspicion of an adulteration of beer with strychnine or any other deleterious substance. It is practically impossible that any operation of a doubtful character could be carried out in these extensive establishments, on account of the large number of workmen employed in them. Any attempt on the part of the brewer to impart qualities to his beer in an illicit manner, which are not to be obtained from malt or hops would necessarily lead to his ruin; as he would be obliged to communicate his secret to too many persons, and to employ too many accomplices. The draymen themselves, as good connoisseurs in beer, would protest against any manipulation of a suspicious character. The case has even occurred of an eminent brewer not venturing to make use of a method suggested to him for the purpose of clearing his beer more effectually, because the addition of a new material to the wort might have induced a suspicion in the minds of his workmen, that it was an illicit proceeding, and this would have endangered the good reputation which his beer enjoyed. He stated to me at the same time that no improvement could be introduced into a brewery, the object of which was not perfectly evident to everybody.

During a sojourn of several days at Burton-on-Trent, I had an opportunity of becoming intimately acquainted with the method pursued in the manufacture of pale ale. I convinced myself that the qualities of this excellent beverage depended mainly upon the care used in the selection of the best kinds of malt and hops, and upon the ingenuity exhibited in conducting the processes of mashing and fermenting. Our Continental brewers have much to learn in these points to come up to the English brewers. I have no hesitation in saying that England possesses the greatest adepts in malting. I know positively that the chief brewers of Munich, who undoubtedly produce the best beer in Germany, have gone through an apprenticeship in Burton. This may account for the predilection entertained by the general public, as well as by medical men, for these varieties of beer; for the instincts of humanity and experience appear to be as good guides in the choice of things that contribute to health and enjoyment as the profoundest philosophy.

Professors Graham and Hofmann, in the excellent report already addressed to you upon the alleged adulteration of the pale ale by strychnine, have indicated a very simple process for detecting the most minute quantity of strychnine contained in beer. I have satisfied myself of the great convenience and accuracy of their method, and have farther assured myself, by an analysis of several specimens of pale ale obtained from London houses, supplied by your establishment, of the utter groundlessness of the imputation that this beer was poisoned with strychnine. I am positive, and am supported in my views by the concordant analyses of all chemists who have occupied themselves with the examination of beer, that the poisoning of pale ale with strychnine has never occurred. I believe I may safely add, that it never will take place; for although an ignorant brewer might be induced from interested motives to add *nux vomica* to his beer, the

word strychnine so forcibly suggests one of the most virulent poisons, that whoever has heard anything about strychnine at all is sure to be aware of this. By adulterating his beer with strychnine, the brewer would be knowingly committing a crime which, in the present state of science, must be followed by immediate detection and punishment.

Mr. E. Merck, of Darmstadt, one of the most extensive strychnine manufacturers in Europe, informs me that this substance is peculiarly adapted to destroy vermin of all kinds. In many parts of Germany it is the popular poison for rats and mice. This fact fully accounts for the large amount of the drug that has lately been introduced into commerce.

The specimens of your pale ale sent to me, have afforded me another opportunity of confirming its valuable qualities. I am myself an admirer of this beverage, and my own experience enables me to recommend it, in accordance with the opinion of the most eminent English physicians, as a very agreeable and efficient tonic, and as a general beverage both for the invalid and the robust.

JUSTUS LIEBIG.

Giessen, May 6, 1852.

COLLEGIATE ELECTION.

The by-laws relating to the election of fellows into the Council appear to have been but little understood, inasmuch as we are informed that only Messrs. Gulliver, Partridge, Shaw, and Tatum, have given notice of their intention to become candidates for the vacant seats in the Council, of which there will be two, viz., the vacancies occasioned by the resignation of Mr. Stafford and the death of Mr. Dalrymple.—*Lancet*.

CHAIR OF MEDICINE, GLASGOW.

Mr. Secretary Walpole has appointed Dr. John McFarlen to the vacant Professorship in the University of Glasgow.

APPOINTMENTS.

Mr. Henry S. Gaye was last week appointed House-Surgeon to the Taunton Hospital.

We have great pleasure in stating that at the last meeting of the Council of the Royal College of Surgeons, Mr. John T. Quekett, the resident conservator of the Hunterian Museum, was unanimously elected Professor of Histology in the College. Mr. John Henry Sylvester, of Cheltenham, late pupil in King's College, was appointed student in human and comparative anatomy, in the vacancy occasioned by the resignation of Mr. D. H. Monckton.

MILITARY.—57th Foot: Acting Assistant Surgeon, T. Clark Brady, to be Assistant-Surgeon, *vice* Jackson, promoted on the Staff. Hospital Staff: Assistant-Surgeon James Jackson, from the 57th Foot, to be Staff-Surgeon of the second class.

PRIZES AWARDED BY THE ACADEMY OF SCIENCES OF PARIS.

We earnestly solicit the attention of our readers to the following list, which will show in a very impressive manner how extensively scientific labour is rewarded in France, and how certain a man of ability and industry

may be of acquiring distinctions adequate to his labours. We refrain from sketching a parallel with this country in this respect: our professional brethren know but too well how scanty are the rewards of scientific labours in this gifted land.

On the 22nd of March, 1852, the public sitting of the Academy of Sciences was held, under the Presidency of M. Rayer, on which occasion the following prizes were announced:—

1. *Experimental Physiology*.—The prize is awarded to M. Claude Bernard, for his paper "On a Newly Discovered Function of the Liver of Man and Animals," wherein the author has brought to light a function of the liver hitherto unsuspected, and shown that the production of sugar belongs as much to the animal as to the vegetable kingdom. 2. A favourable notice is granted to M. Brown Séquard, for his paper "On the Transmission of Sensitive Impressions along the Spinal Marrow." 3. Another favourable notice to M. Dufour, for his "Anatomical and Physical History of Scorpions." 4. A favourable notice to M. Jobert de Lamballe, for his paper "Researches on the Electrical Apparatus of the Torpedo and Gymnotus."

On Unhealthy Trades.—1. A prize of £80 is granted to M. Masson, for having introduced means of preserving vegetable substances, which means are of great benefit to the crews of French vessels. 2. A prize of £80 to M. Sucquet, for the introduction of a process wherewith the unhealthy emanations of dissecting-rooms are neutralized.

Medicine and Surgery.—1. A prize of £100 to M. Guérin, for his "Generalization of Subcutaneous Tenotomy." 2. £80 to M. Huguier, for his work, "Researches on the Diseases which may attack the Female Generative Organs, and especially on Abscess of the Vulva." 3. A reward of £80 to Messrs. Briquet and Mignot, for their "Analytical and Practical Treatise on Cholera." 4. A reward of £80 to M. Duchenne, (of Boulogne,) for his "Electro-Physiological Researches applied to Pathology and Therapeutics." 5. A reward of £80 to M. Prosper Lucas, for his "Physiological and Practical Treatise of Natural Heredity in Health and Disease." 6. With a view of favouring and extending the use of physical agents in therapeutics, the Academy awards £80 each to Messrs. Tabarié and Pravas. To the first gentleman for having originally used compressed air in the treatment of pulmonary affections; as well as for trials of the same means in other diseases in which an increase of atmospheric pressure might appear useful. And to the second gentleman, for his "Essay on the Medical Use of Compressed Air," and for having elucidated, by means of actual observation and the most recent physiological inquiries, facts relating, on the one hand, to the influence of compressed air on the organs of respiration, on audition, on hæmotosis, and the circulation of the blood; and on the other hand, for having duly appreciated its beneficial effects on digestion and assimilation. Finally, for having varied and extended the use of this powerful modifying agent of the organism, and for having ever done so rationally and practically, with results which might hardly have been expected to be so successful. 7. A reward of £80 granted to M. Gluge, for his work "On Pathological Histology," wherein he has studied, with the aid of the microscope, a certain number of alterations of the animal textures. 8. A reward of £60 to M. Gosselin, for his "Researches on the Obliteration of Spermatie Canals." 9. A reward of £80 to M. Gariel, for his medical and surgical applications of vulcanized India-rubber. 10. £60 to M. Vidal, for the invention of "Serre fines," (little silver spring forceps to facilitate union by first intention, which should be more extensively tried in this country.) 11. £40 to M. Serres (d'Uzès), for his "Researches on Phosphenes." 12. £40 to M. Boinet, for his paper on "The Treatment of Congestive Abscess by Injections of Iodine." A favourable notice to the

"Compendium of Practical Medicine," of Messrs. Monneret and Fleury, and to the "Treatise on Nervous Diseases," written by M. Sandras.

By offering this list we are rendering no small service to our readers, for therein they will find which are the most esteemed works that have of late been published in France, and what inventions have, within the last year or two, been found deserving of the approbation of so learned and independent a body as the Academy of Medicine of Paris.—*Lancet*.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 4th instant:—J. Clarke, London; Thomas Hillas, Brompton, Middlesex; Edward John Longport, Lancashire; George Nayler, Hon. East India Company's Service; Robert Reynolds, Debach, Suffolk; Charles Royston, Harrow Road, Paddington; Benjamin Simpson, Dublin; William Snell, Neston, Cheshire; Henry Tournay Stiles, Spalding, Lincolnshire.

The following gentlemen were admitted members on the 11th instant:—Josiah Austen, Plymouth; George Church, Listowell, Kerry; John Andrew Clarke, Army; Savill James Coombs, South Lambeth; Francis D. Kelly, Liverpool; Henry Lankester, Poole, Dorset; James Martin, Quebec, Canada; George Mason, Deal; George Selwyn Morris, Wye, Ashford, Kent; John Barry Murphy, Cork; John Smith, Daventry; John Fremlyn Streatfield, Wanstead, Essex; Thomas Wyld, Ramsbottom, Lancashire.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 3rd instant:—Henry James Ellery, Truro, Cornwall; Charles Dudley Kingsford, Wellington Street, Southwork; Benjamin Richard Lawrence, Cheddar, Somerset; William Boyd Mushet, Coventry.

Gentlemen admitted members on the 10th instant:—James Balfour Cockburn, Guernsey; Thomas William Damant, Fakenham, Norfolk; Henry Richard Foquett, Newcastle Emlyn, Cardiganshire; Benjamin Lawrence Hawkins, as an assistant; John Henry Hewer, Chobham, Surrey; Joseph Hooper, Milton Terrace, Wandsworth Road; William Price Jones, Bala, North Wales; Ezekiel John Lock, Barton, Norfolk; James Rolph, London.

Gentlemen admitted members on the 27th ultimo:—William Charles Rockett; Clark Armstone Duckett, Quadring Eaudike, Lincolnshire; John Edmund, Bangorwood, Flintshire; Charles Harris, Northiam, Sussex; John Hancock Wolstenhome, Bolton-le-Moor; Leonard Keatley Yelf, Ryde, Isle of Wight.

OBITUARY.

June 21st, in Barnsbury Road, William Webber, M.D., surgeon R.N., aged 34.

June 21st, at Star Hill, Rochester, John Lewis, Esq., surgeon, H.P., and in charge of medical stores, Fort Pitt, Chatham, aged 78.

June 2nd, at Bideford, in Devonshire, Henry C. Boisragon, M.D., of Cheltenham, aged 74. Dr Boisragon was one of the oldest members of the Council of the Provincial Medical and Surgical Association, having joined in 1832; he was elected President in 1837, and was subsequently one of the permanent Vice-Presidents, which office he held until the period of his death.

June 18th, at Cambridge, after a few hours illness, Frederick Thackeray, M.D., Consulting-Physician to Addenbrooke's Hospital, aged 78.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

LANCASHIRE AND CHESHIRE BRANCH.

IMPORTANT NOTICE TO MEMBERS.

In consequence of the 8 P.M. train from Liverpool having been discontinued, the Sixteenth Anniversary will be held on Wednesday, the 30th of June, in the Medical Institution, Mount Pleasant, Liverpool, at *twelve* o'clock instead of one, as previously advertised; and the dinner will take place at *three* o'clock instead of four.

ROBT. BICKERSTETH, Esq., Liverpool, President.

JOHN HATTON,

114, Oxford Street, Manchester, Hon. Sec.

SUFFOLK BRANCH.

The annual meeting of the Suffolk Branch of the Association, will take place at the Railway Station Room, Needham Market, on Friday, June 25th,

Dr. BEDINGFIELD, President, in the chair.

JOHN KIRKMAN, M.D.,

Honorary Secretary.

SOUTH-EASTERN BRANCH.

The next meeting of the members of the South-Eastern Branch of the Association, will take place at the Pavilion Hotel, Folkestone, on Wednesday, the 30th inst., at twelve o'clock precisely.

THOMAS MARTIN,

Secretary and Treasurer.

WEST SOMERSET BRANCH.

The annual meeting of this Branch will be held at the residence of H. W. Randolph, Esq., at Milverton, on Wednesday, the 30th of June. The chair will be taken by the President, S. F. Bridge, Esq., at two o'clock.

F. HENRY WOODFORDE, M.D.,

Honorary Secretary.

Taunton, June 19, 1852.

SHROPSHIRE BRANCH.

The annual meeting of the Shropshire Branch of the Provincial Medical and Surgical Association, will be held at the Boreaston Arms Inn, Baschurch, on Thursday, the 8th of July next. The chair will be taken by J. Hickman, Esq., President, at one o'clock. Dinner will be provided at half-past four, for all members who intimate to either of the Secretaries their intention of being present.

T. J. DRURY, M.D., } Hon. Secs.
J. R. HUMPHREYS, }

TO CORRESPONDENTS.

Communications have been received from Mr. Humphry, Dr. Nelson, Mr. Matterson, jun., Dr. Laycock, and Dr. Barker.

In consequence of the great length of the proceedings at the anniversary meeting of the Midland Branch, we are obliged to postpone the insertion of several important communications.

NOTES

ON THE

TREATMENT OF CURABLE DISEASES.*

BY W. S. OKE, M.D.,

Extra-Licentiate of the Royal College of Physicians, Physician to the Royal South Hants Infirmary, &c.

OBSTRUCTION OF THE INTESTINAL TUBE, CONTINUED.

IV.—*Incarceration.*

OBSTRUCTION of the intestinal tube may be caused by incarceration—1st, when a portion of bowel is forced out of the abdomen through one of the hernial openings; 2nd, when it is strangulated within the cavity of the abdomen by bands of fibrinous lymph, by the mesentery or the appendix vermiformis cœci, &c.; 3rd, when it incarcerates itself by invagination. The two last will be alluded to in this place. The symptoms of internal incarceration are, in fact, those of strangulated hernia, except that the external physical signs are wanting. The patient, having been previously in good health, is suddenly seized with severe pain in some part of the belly, which is almost immediately followed by vomiting. From a conscious feeling that something serious has taken place within him, he is at once prostrated by alarm and anxiety. Various medicines are given in the hope of relieving the pain by acting upon the bowels; but these all return—nothing passes; the pain is unabated, and the vomiting continues and increases till it becomes stercoraceous; in short the case becomes what is commonly called *ilius* or *iliac passion*; a term which has not the slightest reference to the cause of the disease.

In the treatment of obstruction from this accident, bleeding to syncope, morphia, the warm bath, distending the colon with copious injections—each containing five grains of the extract of belladonna, and mercury to salivation—are all clearly indicated to relax the grasp that has strangulated the intestine. If these means fail—and alas! fail they generally will—gangrene and death will soon release the sufferer from his agonies. But it must be borne in mind that the fatal issue of such a case does not arise from any impracticability or even difficulty of cure; for it may be truly asserted that if we could accurately diagnose this accident soon after its occurrence, a considerable number of those who perish from it might be saved by the operation of cutting through the parietes of the abdomen, and dividing the stricture. I shall, therefore, mention, some diagnostic signs which would indicate internal strangulation:

1st. Previous good health up to the occurrence of the accident.

2nd. Instantaneous and severe pain within the abdomen, caused either by sudden exertion, external violence, or otherwise.

3rd. Vomiting immediately following such a sensation.

4th. Liability to hernia, although there be no existing protrusion discoverable.

These signs would, I think, be sufficiently conclusive in proof of internal displacement to warrant an abdominal exploration after all the ordinary means had failed. To show the value of the second diagnostic sign, there is a case recorded by Mr. Charles Bailey, of Chippenham, in the *Provincial Medical and Surgical Journal* of April 14th, 1852, in which a young man, aged 25, by falling over some large stones, occasioned a rent in the mesentery, through which three feet of the jejunum were found to have been forced and strangulated. Death was caused by mortification of the incarcerated bowel.

There does not appear to be a much greater risk in laying open the cavity of the abdomen to set free an incarcerated bowel within it than in the operation for a strangulated scrotal hernia of an average size. The division of the integuments, of the peritoneum, and of the stricture are nearly of the same extent; and yet it is remarkable how few cases of the former operation are found recorded, compared with the number of internal incarcerations that must have taken place.

On examining Dr. Hennen's excellent "General Index of the Medico-Chirurgical Transactions," I find only one case of internal strangulation, which was relieved by an operation; and this will be found in vol. xxx, p. 50.

When the patient has been subject to inguinal hernia, lest the obstruction might be caused by a small portion of the circumference of the bowel being grasped by the internal ring, it will be right to try to disentangle it by gravitation before any operation is performed. The attempt may be made in the following manner:—The knees of the patient are to be lifted up and flexed over the shoulders of a strong assistant; and in this position the trunk is to be suspended for some minutes, during which it may be suddenly elevated by the assistant three or four times. I saw one instance in which there was reason to believe this practice succeeded. A labourer, past the middle age, was suddenly attacked with abdominal pain, vomiting, and constipation, for the relief of which all ordinary remedies had failed. Being informed that he had been for a considerable time previously subject to a reducible inguinal hernia, the groin was attentively examined, but no trace of hernia could be detected. Supposing, nevertheless, that a small portion of the bowel may possibly be grasped by the internal ring, he was submitted to the above treatment of gravitation, which was soon followed by copious discharges of fæcal matter, and a favourable termination.

It must, however, be confessed that we shall not often have distinct diagnostic signs of internal incarceration; and that from the want of these, and from the failure of other remedies, we shall be under the necessity of relying almost entirely on the *vis medicatrix nature* to effect some favourable change; and fortunately once now and then such a change is effected.

In the *Provincial Medical and Surgical Journal* of March 17th and 31st of the present year, two interesting cases of recovery from supposed internal strangulation are recorded; the first by Mr. John Soden, of

* Continued from page 297.

Bath, after thirteen days' constipation; the second by Dr. Barclay, of the Leicester Infirmary, after an obstruction of eight days; both of which appear to have recovered by the reparative powers of the constitution.

A few weeks ago Mr. Davids, of Cowes, requested me to accompany him to a case of intestinal obstruction, the symptoms of which appeared to be similar to those related by Mr. John Soden in the case above alluded to; but it terminated very differently. A sailor, of middle age, after eating a supper from oysters, was seized the following morning with griping pain of the bowels, which resulted in obstruction, sickness, &c. The seat of the pain was in the right iliac region, which was tender under deep pressure, and tympanitic. He had been judiciously treated by blood-letting, by aperients, by calomel and opium, and by injections thrown into the sigmoid flexure of the colon. It was about the thirteenth day of constipation that I saw him. He had had stercoraceous vomiting for some days; but at this time it had subsided. There was not much inflation nor pain, excepting from deep pressure over the termination of the ileum, and wind occasionally passed from the rectum. His pulse was 84, regular, and of sufficient volume. His aspect was cheerful, and free from anxiety. Under these circumstances, all active treatment was withdrawn. He was supported with glysters of beef broth, in which were a few drops of laudanum, and a reasonable hope was entertained that he might recover; but shortly afterwards an unfavourable change took place, and he rapidly sunk under the symptoms of gangrene.

On examining the cavity of the abdomen, it was found to contain a considerable quantity of serous fluid, mixed with a small quantity of pus and flakes of lymph. The peritoneum was in some measure inflamed, and the small intestines congested, and of a dark mahogany colour. About three inches above the ileo-cæcal valve the ileum was constricted with a band of fibrinous lymph, not so as to obliterate the cavity of the bowel, but enough to arrest its peristaltic action, impede the circulation, and destroy its vitality. Betwixt the constriction and the valve the gut was dilated into a blackish pouch, and at two points almost perforated by ulceration.

Here is a case of obstruction, which was evidently caused by internal strangulation; and yet there were no diagnostic symptoms which indicated such a cause. The fibrinous band was the result of sub-acute peritoneal inflammation, set up by the irritation of crude undigestible food.

When a portion of intestine has incarcerated itself by invagination, it may be explained by there being an inequality of peristaltic power between different portions of the tube; thus if the normal vermicular action of one portion cannot be continued along another, from its being incapable of maintaining the same degree of action, the stronger portion forces itself within the weaker, and at once doubles the parietes of the intestine; and this doubling process goes on contracting more and more the diameter of the intestinal tube till it becomes choked and impervious.

It appears that children are more liable to intussusception than adults. In a child of three years old, who died of intestinal obstruction, I found three portions of the small intestines which were invaginated. There are, I believe, no diagnostic signs that can be depended upon to indicate the occurrence of this peculiar accident, except that if by a careful manipulation of the abdomen soon after it is presumed to have taken place, any local hardness can be detected in the course of the intestinal canal, such hardness may be fairly imputed to intussusception, and dealt with accordingly. An early operation to disentangle the invaginated bowel is the only possible means of saving the life of the patient that the medical man can suggest; if this proposal be rejected, death will be the result. It is true that a very few cases are recorded (and two in the second volume of the "Transactions" of a Society for the Improvement of Medical and Chirurgical Knowledge, by Dr. Baillie,) where the mortified portion of the gut was separated, and was passed through the rectum; but these are the barest exceptions to the fatality of the rule.

V.—*Impassable Bodies.*

Intestinal obstructions may be caused by impassable bodies, either individually or collectively. By the former, when an indigestible substance is too large to pass the narrow parts of the tube; and by the latter, when a large quantity of crude substances having been swallowed, collect together in some part of the intestinal canal and block up the passage. As there is one part of the tube—the ilio-cæcal valve—which is perhaps more liable to this cause of obstruction than any other, I will briefly describe its construction. It is found where the bowel ileum terminates in the sac of the cæcum, commonly called the "cæcum caput coli." This is not an imaginary but a well-defined termination of the alimentary into the excrementitious intestine. The ileum passes obliquely up on the internal or left aspect of the cæcum, and, having reached the upper part of the sac, empties its contents into it. The valvular opening is elliptoid, and about an inch an half long from point to point. It is formed by two membranes—a superior and an inferior. The superior membrane is of a crescentic shape, about three quarters of an inch in breadth over the centre of the aperture, and with its cornua extends transversely across half the circumference of the cæcum, forming the boundary of the upper part of the sac. The inferior membrane completes the aperture of the valve by a short semilunar margin, the cornua of which are attached to the superior membrane under and a little behind its crescentic margin, consequently the superior membrane of the valve lies over the termination of the ileum. The use of this valve is obvious. It allows an easy passage of the fecal fluid from the small into the large intestine, and prevents its being impeded by the gravitation of the contents of the ascending colon. The inferior membrane, which is in fact the terminating boundary of the ileum, allows of the former, whilst the superior mem-

brane, acting as a kind of roof over the opening when the cœcum is distended, effects the latter.

The symptoms of this case are characterised by great severity. The pain well deserves the term "dolor atrox," and forces the sufferer to vociferate with agony. The severity of the pain may be explained by the sensitive villous coat being compressed from within by an impacted body, and from without by the vehement action of the muscular fibres in their instinctive efforts to propel it along the canal. The vomiting is incessant, and eventually stercoraceous. The abdomen is more or less inflated and tender over the seat of the obstruction; and any movement of the trunk tends to aggravate the pain.

If any crude matter has been swallowed that could account for the obstruction, the diagnosis would be easy enough; but it often happens that the obstructing body is furnished by the morbid action of the internal functions in the form of concretions, and then the diagnosis becomes exceedingly difficult. There is one symptom only, that I am aware of, which can be relied upon, and it is this:—If the symptoms of obstruction above described should suddenly cease, and be followed by liquid stools, and the pain afterwards return with renewed aggravations in another spot, we may be assured the obstruction has been occasioned by a large concretion, which has shifted its place. I will now adduce two examples of this kind of obstruction. The one where the cause was known from its being swallowed; the other, where it was correctly inferred.

Case 1.—A married lady, well formed, aged 26, having just arrived at Southampton from Ireland, incautiously made a hearty meal from stewed mushrooms, and the same afternoon went into a cold bath. Soon afterwards she was seized with most severe pain in the right iliac region, accompanied with constipation of the bowels and incessant vomiting. All the usual remedies—such as bleeding, the warm bath, calomel combined with large doses of opium, and various injections thrown up in the colon were tried; but as these means were of no avail, and as the anxiety for the result became intense, a consultation was held. At this time her sufferings were intolerable; and I well remember how earnestly she implored her medical attendants to perform an operation for her relief. This being considered inadmissible, and everything subsequently recommended having alike failed, she sank and died. Unfortunately permission could not be obtained to examine the abdomen; but there can be no doubt that the mushrooms, which probably had been hastily swallowed and but little masticated, collected *en masse* at the ileo-cœcal valve, obstructed the bowel, and caused her death.

Case 2.—A widowed lady, aged 50, of healthy aspect and rotund form, who had been recently exposed to great mental excitement and distress, was seized with vehement pain of the abdomen, below the umbilicus. Her agonies were extreme, and quickly returned in excruciating paroxysms. The vomiting soon became

stercoraceous, and was so incessant that nothing could be kept down for an instant. On this account it became necessary to abandon all remedies by the mouth, and employ them through the rectum; copious injections were therefore thrown up once about every four hours, which at length succeeded in causing the bowels to discharge a large quantity of fluid fecal matter. This gave relief, and of course promised recovery to herself and all around her; but alas! the cheering prospect was soon again to be clouded over. The pain returned; and although still below the umbilicus, it was felt to be in a different spot. It was of equal vehemence, and with all its distressing associations, and she speedily sank under the renewed severity of her sufferings.

In this case the diagnosis was by no means easy during the first attack, but a ray of diagnostic light broke in upon the second; for the sudden and unexpected return of all the symptoms after the bowels had been freely relieved, and the pain being felt in a different part of the abdomen, could only be attributed to some obstructing body which had moved from its first lodgement to become fatal in the second.

On opening the abdomen a nest of large calculi was discovered impacted in the lower part of the ileum, which was the manifest cause of her sufferings and death. Each of the calculi had smooth flattened phases, showing where it was fitted to others. All might doubtless have passed singly; but the whole being nested together, and crusted over by layers of fecal deposit, a mass was formed, which would not pass the termination of the ileum. The calculi were analyzed and found to consist principally of cholesterine, of which a considerable quantity was obtained in a pure crystalline state. It is scarcely possible that these concretions could have primarily formed in the gall bladder, because I never heard that she had complained of the sufferings which they must have occasioned from time to time in their passage through the biliary ducts.

In the treatment of intestinal obstruction from the lodgement of indigestible or extraneous bodies, all will of course depend upon whether the smallest diameter of the obstructing cause be less or greater than the smallest diameter of the intestinal canal through which it has to pass. If the former, some hope may be entertained from large doses of morphia—say a grain of the acetate once in two hours—a full bleeding, the warm bath, and a belladonna plaster over the seat of pain and repeated copious injections; but if the latter, no cure can be effected by any such means, because it is simply an impossibility. There only remains the "anceps remedium" of laying open the bowel and ridding it of its death-plug. And why should not this be done? There is no difficulty in the operation if there be courage to perform it. The surgeon does not hesitate to invade the trachea with the knife and abstract any foreign body that is threatening life by obstructing the respiratory canal; nor to divide the uterine parietes to extract a fetus that is too large to pass through a narrow pelvis; nor to pierce the colon in stricture of the large intestine. Why then should we hesitate to open the intestinal canal in a case of this kind, to

extract obstructing bodies which are sure to destroy life? If we had ventured to perform such an operation in the cases above stated, it is possible that one or both of the sufferers might have been living at this time. When there is the certainty of death in the one scale, and the possibility of life by an operation in the other, there can be no difficulty in the choice; and although it is admitted to be the "*anceps remedium*," it is nevertheless the "*melius quam nullum*."

It was formerly the practice to administer several ounces of quicksilver to remove obstructions of the intestinal canal, and sometimes it was followed by apparent success; but the case about to be related will, I think, show the absurdity and danger of its adhibition.

A tradesman's wife, aged 50, of stout form and healthy aspect, was seized with severe spasmodic pain on the right side of the abdomen, followed by symptoms of obstruction of the intestines. The disease continued with great severity for several days, and various remedies were tried to subdue it, but as the bowels showed no disposition to act, it was resolved to give six ounces of quicksilver, which were readily swallowed. No relief, however, followed its adhibition, except that the character of the pain became in some degree changed; and shortly afterwards she sunk under symptoms of supervening gangrene.

On examining the abdomen, a large gall-stone, the shape and size of the transverse section of a common-sized mould candle, and two-thirds of an inch in length, which had passed the *ductus communis choledochus*, was found lying in the jejunum; and farther down the quicksilver was detected gravitating in a pouch of one of the convolutions of the ileum, where it had produced mortification of the gut, and thus the intended remedy and not the disease had caused the death of the patient. This must be looked upon as an unfortunate and at the same time an instructive case, showing the great importance of *post-mortem* explorations. It was unfortunate because it appeared that the passing of a large biliary concretion had been mistaken for obstruction of the bowels, the action of which had been merely suspended, whilst an immense gall-stone was being forced into the duodenum. It was instructive because it shows the absurdity and danger of giving quicksilver to remove an intestinal obstruction in quantities that might overpower by its gravity the peristaltic action of the bowel. It might be useful in these cases, if it had run down a continued descent; but as it has often to be propelled against its own gravity by the vermicular force, it is clear that if its gravitating weight be more than equal to the propelling force of the bowel, it must lodge and endanger the vitality of the part on which it lies, as it did in this case.

VI.—Organic Disease.

Obstruction from this cause is not of rare occurrence. In my own practice I have met with many instances. Organic disease, especially when situated in the cavity of the pelvis, may cause a total obstruction of the intestinal canal simply by external pressure, an instance

of which I have lately seen terminate fatally in this town, independent of any disease of the bowel; but it more commonly obstructs the canal by involving the bowel in its morbid action. The latter cause is that which will be treated under this head.

Organic stricture is generally met with in the large intestine, and more frequently in the sigmoid flexure of the colon and in the rectum. I have but seldom seen it occur in the small intestine between the pylorus and the termination of the ileum. It is always eventually fatal; for although a patient may survive a few attacks of obstruction, he is sure of being destroyed by the disease as the canal becomes either blocked up by it or perforated. The symptoms are much the same as in other intestinal obstructions, except that the pain is comparatively less spasmodic, and that, if the stricture be situated low down in the colon or in the rectum, the abdomen becomes inflated to an enormous extent, indeed I have so frequently seen extreme tympany in these cases, as to consider it almost diagnostic of this disease.

In some instances, before the first obstruction takes place, there is a sickly aspect and an occasional feeling of illness; whilst in others the general health is unimpaired, so that the patient is not at all aware that so serious a disease exists within him. When this disease is situated in the excrementitious part of the intestinal canal, it does not much atrophise the body; but on the other hand, when it involves the alimentary portion there is great emaciation, as we find in disease of the oesophagus, the pylorus, or of the small intestine. The following case was attended with previous illness:—

Admiral Sir Samuel W., of sallow and unhealthy aspect, aged 70, had felt himself ailing for a considerable time, which he attributed to bilious causes. He was not much attenuated and thought lightly of his complaint. At length he was attacked with severe pain in the left side of the abdomen, associated with obstruction of the bowels and vomiting. Every means were employed that could be suggested to mitigate his sufferings and move the bowels, but without any good effect. The disease went from bad to worse, the transverse arch of the colon and the intestines above it became enormously inflated, and he rapidly sunk. On examining the intestinal canal no obstruction was found till we came to the descending portion of the colon as it passes over the left kidney. There a carcinomatous stricture was discovered, which involved about two inches of the length of the bowel; and at this point the aperture was so contracted as not to admit the end of the little finger. The crown of one of the molar teeth was lying upon it.

The next case will show that an extensive scirrhus stricture might for a long time coexist with the possession of apparent good health.

A lady, aged 55, of fair complexion, plump form, and remarkably healthy aspect, who had been long accustomed to daily walking exercise, became at once affected with pain of the lower part of the abdomen, and

all the sufferings of obstructed bowels. These symptoms took her by surprise, as she had always enjoyed uninterrupted good health and had rarely occasion to resort to aperient medicine. Various means were tried to relieve her, but as they did not succeed it was deemed necessary to explore the rectum, when its upper part was found almost impervious by indurated masses of scirrhus disease. She was at length relieved principally by the introduction of a wax bougie and diluent injections; but a few months afterwards, when residing near London, she died of a second obstruction.

In the case also about to be related the general health was not previously impaired, and it will be found interesting from a trocar having been used to lessen the inflated distension of the colon.

A lady, aged 35, of fair complexion and well nourished. but of delicate constitution, was attacked with the symptoms of severe colic, the pain of the abdomen returning in vehement paroxysms. The case was obstinate, and resisted the remedies employed in the way of aperients, calomel and opium, enemata, the warm bath, &c. After some days the colon had become inflated beyond anything of the kind I had ever witnessed, so much so that the inaction of the bowels was reasonably attributed to the loss of peristaltic power from overdistension, and in consultation with Dr. Wood and Mr. Simpson, it was agreed that the transverse arch of the colon should be perforated by a fine trocar, and the rectum injected with cold water at given intervals. The first was done at once by the latter gentleman, and a large quantity of foetid gas escaped by the cannula; this caused the volume of the abdomen to subside, and by the repeated injection of cold water, a considerable quantity of liquid faecal matter passed the bowels. This was highly encouraging, but the improvement was only temporary. The symptoms of obstruction returned, the colon became again inflated, though in a less degree, and in about twenty days from the commencement of the attack she died.

The body was examined, and at the inferior termination of the sigmoid flexure of the colon, where the gut is about to enter the cavity of the pelvis, an organic stricture was detected, of a carcinomatous character, which, although it did not involve more than an inch of the length of the bowel, had almost closed the tube.

By an attentive examination of the symptoms, the diagnosis in intestinal obstruction from morbid stricture will not be difficult. The rectum should always be explored, either by the finger or a bougie, and if there, the disease will at once be discovered. If the rectum be found free, then, if the aspect of the patient have been for some time sallow and sickly,—if there be want of nutrition and wasting,—if the abdomen has been occasionally affected with darting pains, and be resonant under percussion,—if the stools have been previously relaxed, unhealthy in appearance, and mixed with blood and mucus,—and, in addition to these signs, if there have been previous obstruction, an organic stricture is clearly indicated.

In the treatment of this case all harsh measures are to be carefully avoided; and with a view to overcome any spasmodic or inflammatory action which the irritation of the stricture might have induced, it will be right to give half a grain of opium, and two grains of calomel, every two hours, whilst the pain remains, after which the draught (1) should be given every three hours till the bowels are acted upon:—

1.—R. Magnesiae Sulphatis,
Mannæ Optimæ, utrque, dr. ij.
Misturæ Amygdalæ, dr. x.

Misce fiat haustus.

If there be no action from these means in four or six hours, it will then be necessary to throw up into the sigmoid flexure, once in four hours, a copious glyster of warm water, with four grains of the extract of belladonna, in the hope of dilating the constriction sufficiently to let the faecal discharge pass through it.

This treatment may succeed once or twice, but eventually, as the intestinal canal is more and more filled up by the morbid growth, all remedies of this kind must fail. To save life under such imminent danger, M. Amussat, a French surgeon, in 1839 introduced the practice of perforating the colon above the stricture at some point where the wounding the peritoneum could be avoided, *i.e.*, through the lumbar region. This operation since that period has been performed many times by English surgeons, and sometimes also through the peritoneum; and it is probable that the latter has been occasionally preferred on account of the difficulty of maintaining an artificial anus through the depth of the lumbar muscles.

At a recent meeting of the Royal Medico-Chirurgical Society, Mr. Cæsar Hawkins read an important paper on this subject, and having related a successful case in his own practice, he brought forward tables showing the results of this operation, in various points of view, which occurred in 44 cases. In one of these tables it appears, that of 43 cases 21 had died within the first five weeks, and of these that ten had died within forty-eight hours; that 22 only could be fairly stated to have recovered from the operation, that of the 22 six had died in about six months from the time of the operation, and that only nine patients were at present known who had survived it more than one year, one of whom (Mr. Clement's case,) lived three years, and another (Mr. Maitland's,) lived seventeen years.

This statement is certainly discouraging; but when neither scirrhus nor carcinoma is *known* to characterise the stricture, when the obstruction is in the large intestine, and when the constitution does not appear to be much exhausted, the operation is justifiable, and if it can be performed without wounding the peritoneum, there will be a greater probability of success.

The constitution appears to sanction this mode of proceeding by sometimes taking the same course. Although the following case would in nowise have justified the operation for its own relief, still, as it will show the ulcerative process by which a communication was effected between the cæcum and the external part of the abdomen, and, as it is interesting in other points

of view, I will briefly relate it, and conclude the subject:—

J. J., of tender age, quick intellect, slight conformation, and delicate constitution, became gradually ailing with symptoms of mesenteric disease. The abdomen was swollen and painful, he lost flesh, and his general health declined. On this account he was placed under the care of eminent medical men in London, who sent him for a time to the sea-side; the disease, nevertheless, steadily though slowly advanced, and whilst the enlargement and tenderness of the abdomen increased, the rest of the body became attenuated. At length the quantity of the alvine discharges, which were of a pale-white colour, was observed to decrease, and as the quantity became less and less, an abscess was discovered to be forming externally on the right side of the abdomen, below the umbilicus. When it broke the faecal smell of the discharge at once proved that it came from the cavity of the intestine, and very soon afterwards a calculus, of a whitish colour, and about the size of a nutmeg, was found on the poultice. This abscess was succeeded by another more posteriorly; and through these openings several more calculi, of nearly the same size and colour, were from time to time expelled with the faecal matter. The expulsion of these concretions gave some hope of recovery, and every effort to effect it was redoubled, but no improvement took place. All the stools continued to pass through the abdominal openings, he became colourless and atrophied, the peritoneum infiltrated, his lower extremities anasarous, and he gradually sank from exhaustion.

On examining the abdominal viscera, the omenta and peritoneum were found studded with a multitude of small tubercles; and the mesentery, from the quantity and size of the tubercular masses it contained, was like a net bag full of white marbles. The external openings communicated with the cavity of the cœcum, which had become the seat of an abscess, extending almost as high as the transverse arch of the colon. The involved portion of the gut was fixed by peritoneal adhesions superiorly to the acute margin of the large lobe of the liver, laterally to the omentum majus and small intestines, and inferiorly to the fundus of the bladder. The cavity of the cœcum at its inferior extremity was freely open to the ileum; but its superior part was so blocked up by a fungoid growth that it would scarcely allow of the small end of a blow-pipe being passed into the transverse arch of the colon. The internal surface of the bowel presented a mass of chronic and irregular granulations of a dark red colour, some of which were elevated into nipple-like processes. The same dark colour pervaded the villous coat of the intestinal canal at either end of the disease, and that of the ileum, close to the ileo-cœcal valve, was extensively ulcerated.

The *rationale* of this interesting case may be summed up in the following order:—Debility of constitution; tubercular diathesis; tubercles of the mesentery more actively developed; atrophy; softening of the tubercular matter in the villous coat of the cœcum; super-

ficial ulceration of the same, extended and kept open by the irritation of faecal matter; granulations shooting up, and by degrees obstructing the passage of the colon; formation of concretions by the gradual deposit of the phosphates upon indigestible nuclei, namely,—orange pips, apple pips, &c., which were found in their centres; and lastly, ulcerations through the abdominal parietes, to expel the calculi, and serve as an outlet for the fæces.

[To be continued.]

Southampton, May 17, 1852.

REMARKS ON THE TREATMENT OF BURNS AND SCALDS.*

By W. J. MOORE, Esq.,

Resident Surgeon to the Queen's Hospital, Birmingham.

BURNS or scalds involving the neck and upper part of the chest, are undoubtedly to be dreaded more than those of other parts of the body; first, from their tendency to terminate fatally, either by laryngitis or pneumonia; and secondly, from the great difficulty of preventing the deformity so liable to occur in such a situation during the healing process. Bandages and splints are here not easily applied; and it likewise requires much firmness, both on the part of the patient and surgeon, to prevent the head from inclining downwards. If a patient, severely burned, does not die of the collapse consequent on the accident, there are still other grave causes of danger, most frequently, perhaps, having reference to the respiratory organs, congestion of the lungs, sometimes complete pneumonia, and more rarely laryngitis, coming on. Sometimes, however, there is no collapse present, and the patient goes on well for one, two, or three days, when suddenly the breathing becomes difficult, the pulse perhaps being increased in volume, and countenance flushed; in a short time, however, (an hour or two,) the extremities become cold, the pulse intermittent, and the patient rapidly dies by asthenia; at other times he seems to rally from this state, and then the lungs certainly become affected.

When a patient is seen thus, the difficulty of breathing having come on suddenly, it is often a nice point to diagnose the probable termination, and therefore to determine with certainty the proper treatment. Supposing the case to terminate by asthenia, wine and brandy should certainly be administered; but if given, and the patient should survive and have pneumonia, they will without doubt do injury. Leeches, with antimony, are here called for; and with children the application of two or three to the spine, and the exhibition of small doses of antimony, combined with tincture of cardamons, has often been followed by success.

Amongst the numerous affections which may arise after a burn, I may mention the phenomena of epileptic convulsions. These probably depend on irritation of the peripheries of the nerves, and may be relieved by immersion in warm water, or sometimes by the exhibition of full doses of tartar emetic, to produce vomiting. In this latter case, however, it will generally be found that the stomach has something to do with the convulsions; and it will be likely that the child has been eating some rather indigestible substance prior to the burn, which the stomach, sympathizing, as it necessarily must do, with the disturbance of the whole system, is unable to digest, although in a state of health it would have done so with ease. I therefore always inquire if anything likely to disorder the stomach has been taken latterly, and then (*ceteris paribus*) act according to the information obtained. Relief frequently follows vomiting, just as we find the same thing happen in convulsions from a similar cause, where there is no complication of burn. In our inquiries it is well to bear in mind that an article which would not cause irritation in a healthy state would do so after a scald or burn.

Another cause of death, but one which happily occurs rather seldom, is tetanus; sometimes partial, sometimes involving the whole muscular system. If this complication happens the case must be considered all but hopeless; and it is therefore good that it does not more frequently occur, particularly as the suffering then experienced must be of a horrible description. One case of lock-jaw, following a superficial burn of the chest, just now occurs to my recollection, where it was with the utmost difficulty that any sustenance at all could be administered. The trismus came on gradually, commencing on the fifth day, and the girl died on the thirteenth in an asthenic condition. Such a case, although bad, does not strike the beholder with such horror, as others were opisthotonos or the other forms of spasms are present. A friend of mine, who holds large colliery appointments, and often has occasion to treat burns, informs me he some time back had two cases where opisthotonos was observed; and, what is strange, they occurred both within a very short time of each other. The treatment in the one case was stimulating, in the other the reverse; but both were equally fatal in their termination.

When we consider the numerous complications which may arise and endanger life during the progress of a burn, we naturally turn to *post-mortem* appearances, as a means of elucidating some fact, and throwing some light on a sufficiently dark subject. But here we are defeated; for it often happens, particularly in cases such as those last mentioned, that morbid anatomy adds nothing to the subject. It is true there are certain appearances often met with after death from burning; and it is likewise true that inflammation and congestion of various organs show their presence by their appropriate signs—serous effusions and the like; but when the nervous system has to be searched, we in vain look for the causes of convulsions—epilepsy, tetanus, &c. In the case referred to above, where trismus resulted, there was no evident cause for such

affection. The brain was but little congested, and apparently healthy in structure, and the medulla spinalis was also free from morbid appearances. I regret I have no account of a *post-mortem* on the other cases; but from a consideration of the morbid appearances usually found in tetanic cases, I do not apprehend much would have been elucidated.

After a burn has healed, and a cicatrix formed, it often happens that it becomes a question if any operative interference will relieve the state of contraction too often present. Much depends upon the depth of the burn in the first instance, as should the muscular structure be destroyed, no good can possibly result from any interference whatever; thus in a case latterly brought under notice, the whole of the triceps muscle on the posterior part of the humerus was destroyed, and the integument and periosteum of the bone firmly united for some distance up the arm; the forearm was extended, and of course could not be flexed, there being little or no motion of the elbow-joint. The deformity is irremediable.

Sometimes, however, when the cicatrix and contracted portion is not very firm, and cartilaginous, some good may be done by the use of the knife, either dissecting off the cicatrix, or dividing the prominent bands resulting from it. This, however, frequently fails, as the new granulations have the same tendency to contract exhibited by the old wound. I have never seen subcutaneous section tried for the cure of such deformities, but am of opinion that good would result from its adoption; the hardened tissues beneath the integument being divided, and the integument stretched, which it would allow of when the resistance beneath was gone; the integument, although newly formed, and perhaps but partially organized, evidently retaining more elasticity than the condensed fibro-cartilaginous structure found in these cases beneath it.

Sometime ago I had occasion to treat a case of very bad contraction following a burn, of which the following is a brief account:—A lad about twelve years old, had the misfortune to get severely burned about the back, left axilla, left arm, and side of the chest. In the course of time the wound had almost healed, but the arm remained nearly touching the side from the contractions which had taken place, and therefore motion was almost lost. Under these circumstances screw splints and other contrivances of the kind were brought into requisition, but with little, and only temporary benefit to the arm. One morning while attending to the case, I was inducing him, as was my habit, to move the arm as much as possible, and to aid him in the attempt applied my hand to raise the elbow from the side, exerting but a slight degree of force. That force, however, was sufficient to rupture much of the newly-formed material and a gaping wound resulted, some five inches in extent, and passing horizontally round the chest, about two inches below the axilla. It was not in a line but very zig-zag in direction, which, as afterwards proved, was a great means of procuring a better medium of union. The dressings were lint and water; and presently, from the numerous promontories of integu-

ment spoken of, fresh skin began to form, so that when it was again healed, there was very tolerable motion of the arm.

I have not had many opportunities of trying rupture of contracted parts, but in one other case where the contraction occurred in front of the elbow-joint, the same means were adopted, and with much success. Should I have cases of a like kind to treat, I should feel disposed to follow out the plan; at the same time I would, for two or three obvious causes, limit its employment to recent cases. There also seems to be no reason why the same principle should not guide the knife in cases of this description. Instead of dissecting the cicatrix, or dividing it, as is usually done, I would make incisions in different directions, and even leave small detached portions of integument, and thus imitate what occurs when the parts are ruptured by force. Each promontory or isolated portion of integument becomes as it were a spring, from which new matter is formed. This suggestion, however, requires to be practised, ere its efficacy can be fully established, and I probably shall practise it in a case now under my treatment, and give the results to the profession.

CASE OF

WOUND OF HEART BY A NEEDLE.

By FLOYD PECK, Esq., NEWMARKET.

*Read at the St. Ives Meeting of the Cambridge and Huntingdon Branch,
June 16th, 1852.*

ELLEN PAVIS, aged 6, a healthy child, was observed to come home crying about eleven A.M., on Friday, August 1st, 1851. She complained of pain in her chest till about one o'clock, when some tea was given her and she became better, and played about till evening, when she became sick and continued so all night. About two P.M., she brought up worms, and at eleven A.M., on Saturday, she became worse, and the Union Medical Officer was applied for. The Relieving Officer came to see her, but finding her asleep did not think the case sufficiently urgent to require a doctor, consequently she had none. She complained of pain sometimes in the belly, sometimes in the chest, till she died, at eight, P.M. on Saturday.

I was requested by the coroner to examine the body, which I did forty hours after death.

The abdomen was first examined, but all the organs in it being healthy, the chest was next inspected. In separating the sternum from the anterior mediastinum, the scalpel struck against a metallic body, which proved to be a stout and strong needle, which had been thrust through the junction of the sternum with the cartilage of the third rib, and broken off short externally. A corresponding small spot was then noticed on the skin of the chest, but which, under ordinary circumstances, would have attracted no attention. The part projecting inwards measured about an inch, and had wounded one or two mediastinal veins, and made a small opening into

the pericardium, which was full of blood. There was considerable bloody infiltration into the tissues around. The lungs were congested. The external wall of the right ventricle of the heart was frayed as it were by the point of the needle, in a peculiar manner. On making closer inquiry, some complaint had been made by the child of a needle she had in her pinafore having been broken and pricked her. The points of interest in the case seem to be the unsuspected existence of so serious a lesion, and the absence of any detailed symptoms which might have led even a medical man, had she been seen by one, to have inferred any injury of that nature. The situation of the injury to the heart would indicate with much precision the movements of that organ to be two fold—up and down, and over from right to left.

TWO CASES OF VITILIGOIDEA.

By W. FOSTER, Esq., HUNTINGDON.

*Read at the Meeting of the Cambridge and Huntingdon Branch,
St. Ives, June 16, 1852.*

ABOUT twelve years ago I saw a young lady with a curious affection of the skin of the neck, traversing the left side diagonally from the ear towards the sternum, about one inch in width. At first sight it appeared as the scar of a burn, or skin removed from some superficial cause, not unlike a prolonged scar from the pustule of vaccination, but at the lower part the skin was elevated for a short distance, smooth, and of a colour something like a permanent wheal of urticaria; it seems that it spread by this elevation, which was succeeded by the scar-like appearance; there was no pain or uneasiness; the general health good. The appearance was anything but prepossessing, but as no indication of treatment presented itself, the case passed away with the impression on my mind "that I knew nothing about it." I saw the young lady the other day; there is a very slight elevation just above the collar bone, and the scar-like appearance is much more superficial, and has now nothing more than a dirty appearance.

I saw no other case until last autumn, when a young gentleman, just about to enter Oxford University, showed me what I recognised as the same disease. It appeared in his case after suppressed perspiration, as he supposed; it shewed itself just above the left eyebrow on the forehead in one or more patches. I recommended him to try collodion and *live well*. I could not give him the name of the disease, nor say more about the treatment. I heard from him soon after, when he stated the same affection had all at once darted up his head for about an inch and a half in length, and one in width, entirely destroying the hair at the roots. He applied the collodion assiduously, took more animal food, and a few weeks since I saw him, the disease was evidently stayed on the head, (but the hair had not grown in the least,) also on the forehead it was healed,

but just on the eyebrow it was not gone. He complained of a sense of stiffness over the parts affected, and expressed himself very anxious as to the results. Very soon after this latter case presented itself, I found this disease described by Dr. Addison and Dr. Gull, in Guy's Hospital Reports, vol. vii., p. 2, under the name of "Vitiligoidea."

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES

Reported under the terms proposed by the Association.

By SCRIVATOR.

Fractured Skull; Depression of Bone; Laceration and Loss of a portion of the Brain; Removal of Depressed Bone; Death.

HENRY HOLLIES, aged 16, admitted November 21st, under the care of Mr. Parker. It was stated that he had just been knocked down and kicked by a boat horse. There was shivering, paleness of the features, and cold extremities; the pupils were contracted, the pulse intermittent, and the heart's action feeble and irregular. There was a wound in the scalp above the right ear, and somewhat profuse bleeding from the arterial branches situated there. On examining the wound, there was found a depressed fracture of the skull, the depressed portion of bone seeming to be about the size of a shilling. It was situated obliquely, one portion projecting from the wound, the other evidently having entered the cerebral substance for some distance. There was also another portion of bone depressed, triangular in shape, and as much as an inch in length, the base of the triangle being applied to the posterior surface of the rounded depressed portion. There was also considerable escape of the cerebral substance itself, as much as a teaspoonful having found its way through the wound. There was a bad cut on the forehead, and another over the occiput.

When seen by Mr. Parker, a short time after admission, the surface had become much warmer, and the pulse of better calibre. He was also sensible, and would answer any question put to him, lying in the meantime perfectly still, and evidently much disinclined to any mental exertion. Mr. Parker determined to raise that portion of bone which was lacerating the cranial substance, and in order to accomplish this was obliged to enlarge the opening in the scalp. This having been effected, several loose portions of bone were readily removed by the forceps, the largest of them being the round portion before mentioned as tilted inwards. During the operation some more of the substance of the brain escaped, but the boy still continued perfectly sensible, and could tell the number of fingers, or any object held before him. Wound to be dressed with plasters.

Vespere.—Still continues sensible; surface is hot; pulse counting 90; countenance slightly flushed; has made water, but bowels not open.—Hab. Ol. Croton, grt. j.

22nd.—Bowels have been moved during the night; he is still sensible but appears stupid, and answers very deliberately, and with evident exertion; pulse counts 96, and is intermittent; head is somewhat hot, and countenance slightly flushed.—To have an injection of castor oil.

Vespere.—Pulse 100, full; head hot; countenance flushed; restlessness; surface dry; bowels not moved.—Mittatur Sang. ex brachio ad, oz. xviii.

23rd.—Has passed a very quiet night, and appears going on well. He is perfectly sensible; pulse counts 90; surface moist; bowels open; tongue moist.

Vespere.—Going on well. To have effervescing draughts.

24th.—No bad symptom present. Strong beef-tea. Wound to be poulticed, as it had put on rather a sloughy appearance.

25th.—Still going on well.

26th.—About the same. No prominent symptom; pulse 90, and moderate as regards force; tongue clean; quite sensible. Takes broth and beef-tea with readiness. Bowels confined.—Hab. Haust. Purgant, oz. ij. statim.

27th.—Does not appear so well this morning, being somewhat hot and feverish; he has been restless during the night, and several times wished to get out of bed, &c. Pulse does not exceed 90, but the tongue is slightly furred.

28th.—Although sensible this morning, he has been delirious during the night, trying to get up, and talking about his friends and employment; pulse counts 90, and is soft; bowels open; tongue furred. On examining the wound there is a slight protrusion of the cerebral matter, which it is stated was first noticed yesterday; it pulsates regularly, and appears likely to become a large hernia cerebri. The edges of the scalp-wound are granulating.—R. Ant. Pot. Tart., gr. ij.; Liq. Opii. Sed., dr. j.; Aquæ, oz. viij. Fiat mist. sumat. oz. j. quartis horis.

Vespere.—Has had two doses of the medicine, and is now much less restless; pulse counted 90, and is reduced in volume; appears inclined to sleep, but makes no complaint, although he continues quite sensible.

29th.—As before in every respect. Takes his beef-tea, broth, &c., well.

30th.—Appears weaker to-day, and the pulse is not so strong as before; the tongue is also brown and dry, although sensibility is perfect. To continue beef-tea with wine in addition.

Dec. 1st.—Is evidently growing weaker, and lapsing into a typhoid state. Continue aliment.

2nd.—Died: having gradually become comatose, with dilatation of the left, and contraction of the right pupil for some hours before death. The wound the last day or two has assumed an ashy pale hue, but without further protrusion of the cerebrum.

Post-mortem.—There was extensive wound of the brain, which appeared to communicate with the lateral

ventricle. The hole in the bones of the skull was found to correspond with the pieces taken away, and there was also an extensive deposition of lymph over nearly the whole surface of the base of the skull.

MARY HALL, aged 6, was admitted as an out-patient under Mr. Sands Cox, in February last, having a portion of the skull, the size of a crown piece, depressed to the depth of the one-sixth of an inch. The fracture was situated at the superior part of the occipital bone, and the depressed portion was perfectly sound. It appeared the child had been thrown down four days before on some hard stones, a large swelling on the head immediately forming afterwards. The tumefaction had now in a great measure subsided, and the depression was very evident both to the sight and touch. The child had complained of headache, but no prominent symptoms had been present, and when brought to the hospital, sight, hearing, and every other faculty were perfect. She was ordered a few calomel and jalap purges, and attended several times. She is now quite well, never having made any complaint. The depression remains.

Wounds of the brain are certainly amongst the most dangerous injuries to which the human frame can be subjected, and are popularly supposed always to be fatal in their results; but it is now well known that occasionally such lesions are recovered from; and instances of such a nature may be found, in most surgical works, and moreover, are frequently recorded in the medical journals of the day. Fracture and laceration, with loss of a portion of cerebral matter, as exemplified in the first case reported, are not of necessity attended with loss of life, and even may exist without the occurrence of any bad symptom; there being instances of recovery from such state. This is not only interesting as a physiological fact, but is also important in a medico-legal point of view; as ere now it has been questioned if a person could commit any act requiring the exercise of the mental faculties, with the brain injured to such a degree. Dr. May mentions a case where the man walked two or three miles with fractured skull, lacerated brain, and ruptured lateral sinus,* and Cooper also mentions another of the same nature.†

Regarding the treatment of these cases it has now become the established practice of all experienced surgeons to "leave well alone," that is to say, although depression of bone be present, not to attempt elevation unless there be some urgent symptoms of coma or pressure. This is certainly correct, there being no external scalp wound; but the integument already being open, authorities differ concerning the exact line of practice to be followed. If, however, it can be ascertained as in the case reported, that any portion of bone has penetrated, and remains undoubtedly irritating the cerebral substance, there seems to be no question of the propriety of removing that which is to all intents and purposes then a foreign body. The symptoms observed

during the progress of the case were oftentimes similar to those of delirium tremens. One fact is also worthy of notice, that the tendency was to a typhoid condition, which would seem to point to the propriety of keeping up the *vis vitæ* by nourishing diet, and not applying antiphlogistic remedies to too great an extent in such cases.

The second case reported exemplifies the tolerance of pressure the brain sometimes shows. At such an age the diploe of the bone would be so small that the pressure would be exercised directly internally. Probably, however, from the situation of the fracture, the cerebral substance has somewhat escaped, the depression being directly over the base of the superior longitudinal sinus, and the upper part of the torcular Hierophili.

Provincial Medical & Surgical Journal.

WEDNESDAY, JULY 7, 1852.

WE may remind our Associates that the Twentieth Anniversary Meeting will be held at Oxford, on the 21st and 22nd of the present month, when those who have not already visited that University will have an opportunity of inspecting all those local features which must be so well known to them by report; whilst others will be able to renew their acquaintance with them, to which the interval can only add fresh zest and relish. In addition to the interest attached to the locality, may be mentioned that connected with the ceremony of conferring the degree of D.C.L. upon our distinguished Associates, Sir CHARLES HASTINGS, Dr. FORBES, and Dr. CONOLLY, a compliment equally deserved by the individuals, and due to the Association.

The questions which may be expected principally to take up the attention of the meeting, are those of Medical Reform, and the management of the publications of the Society. The former, we think, is in such a train as to give unmixed satisfaction, and the only point at all likely to lead to discussion is the apportionment of the sum to be devoted to the further superintendence of the Bill, which having already been approved of by the District Branch Meetings, will, we have no doubt, receive the assent of the assemblage at Oxford. With regard to the publications, we have already adverted to them, except upon one or two points, upon which some of our readers have required explanation, and which will be alluded to below. It is proposed by the Worcester Council that the consideration of this question should be referred

* *Provincial Medical and Surgical Journal*, Jan. 9, 1850, p. 10.

† Cooper. Med. Dic.

to a Committee, but we are inclined to think that it would lead to a more satisfactory result if the discussion moved for by Dr. COWAN should be allowed to take place in the general meeting, since it is one in which all the members are equally interested, and equally capable of forming a correct opinion.

We are requested by the LOCAL SECRETARY at Oxford to call the attention of the members of the Association to the notice put forth in the programme of the proposed proceedings at the meeting to be holden in Oxford on the 21st and 22nd inst.:—"Local circumstances make it indispensable that for securing suitable accommodation, gentlemen who purpose to join the Breakfast or the Dinner Party on Thursday, the 22nd inst., do make intimation of such intention to the Honorary Secretary, R. HANSARD, Esq., 31, High Street, Oxford, on or before SATURDAY the 10th inst."

Members who intend to visit Oxford on the occasion are particularly requested to call at the TOWN HALL IMMEDIATELY ON THEIR ARRIVAL, where all necessary information respecting the Meeting will be supplied to them.

On WEDNESDAY, July 21, a table d'hôte BREAKFAST will be provided at the STAR HOTEL, from 8 till 11 o'clock, Tickets 2s. 6d. There will also be a table d'hôte DINNER at the STAR HOTEL, at half-past five, Tickets 4s., exclusive of Wine and Dessert.

On THURSDAY, the Members and their Friends will BREAKFAST together at the STAR HOTEL, at Half-past Eight o'clock, Tickets 2s. 6d. each; and on the Evening of the same day, they will DINE together at the TOWN HALL, at Half-past Six o'clock, Tickets One Guinea each, including every expense.

Beds at the several Hotels, 2s. 6d.

IN connection with our remarks on the conduct of this journal, we have received several letters, some for our private perusal, and one signed "W.," for insertion in the present number. Most of them contain a demand for an explanation, which will be found in this article, relative to the items of expense in its printing, editing, &c., together with other observations to which we will also allude, and to which this notice we hope will supply a full and satisfactory reply.

Our correspondent, "W.," in comparing the expense of the publications of the Society with that of the *Medical Times*, estimates this journal at 19s. 4d. per year. Now, so far from

this being the case, according to the following calculation, it costs each subscriber, in round numbers, 10s. only. The charge for printing amounts to £700 per annum, which, together with the expense of editing, after deducting the receipts for advertisements, sale of extra journals, &c., average as near as may be £800 yearly. This expenditure we believe to be as low as it is possible to reduce it, if conducted in the usual way of employing a respectable printer and publisher, and instead of exceeding that of the *Medical Times and Lancet*, is beneath them by more than one-third, since the sum named by "W.," is only the subscription for the unstamped paper, whereas the charge for the *Journal* includes that important item. The *Lancet* is furnished, stamped, for £1. 14s. 8d. per fifty-two copies, making the charge for twenty-six numbers—the number furnished by us—17s. 4d. Thus we think we have shown to the satisfaction of every one, that in a commercial point of view the Association cannot be said to have been supplied with "a bad article at a high price," which has been the remark of one of our private correspondents. We may thus dismiss the subject of the *cost of the article*, which, as we before observed, we believe to be reduced to the lowest possible price, unless printed by the Society on its own account, when of course the fair and reasonable profit of the printer might be retained by the Association, but which it has hitherto declined to interfere with.

Now, as to the reasons which may be alleged why the Editorial matter has not what our friend "W." requires—"more spirit in it," our readers are probably aware that on more than one occasion cold water has been thrown upon any discussion of medical politics, and that any unfavourable opinion awarded to any book in its review, has been thought to be prejudicial to the interests of the Association; so that we think that it must be evident to any unprejudiced mind that the subjects upon which to exercise our ingenuity are materially limited, and that we are somewhat in the position of a man thrown into the water with his hands tied, who is abused for not readily swimming to shore. We can assure our correspondent that there is more difficulty in reducing the "spirit" of our effusions to the desirable standard than there would be in instilling enough to satisfy even him.

We have before alluded to the importance of our Associates supporting our efforts by their

contributions, but here again there is no little difficulty in avoiding both Sylla and Charybdis, since we have found on more than one occasion that fault has been found, (and we have no doubt arising from real injury in a limited circle, to the extension of the Association,) with our refusing admission to articles unfit for the pages of a medical periodical or in some cases for any periodical at all. We are well aware that it is impossible to please all parties, and that in the exercise of our duties we cannot possibly avoid wounding the *amour propre* of some, but we can conscientiously affirm that we never exceeded what we thought our duty, and we can with thankfulness recal many instances in which the contributors themselves have most handsomely admitted the truth of our objection. Still there are reasons for the admission of many articles, which perhaps the Editor of an independent *Journal* would reject, but when it is considered that the promotion of journalism is not the sole object of the Association, but that it can only be usefully carried on by making all its several purposes run on smoothly, *pari passu*, we think we have exercised a sound discretion in sometimes sacrificing the interests of the *Journal* to those of the Association at large, and from many years' experience of the working of the two, we are quite confident, that whoever conducts the one without reference to the other, will irreparably injure the whole cause, and put a stop at once, not only to the progress of the *Journal*, but to the Association itself.

Proceedings of Societies.

YORKSHIRE BRANCH.

THE annual meeting of the YORKSHIRE BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION was held at the Medical School, Leeds, on Thursday, June 10th. There were present—Dr. Chadwick, of Leeds, President; Mr. Hey, Mr. S. Hey, Mr. T. P. Teale, Mr. S. Smith, Mr. Garlick, Mr. Price, Mr. Nunneley, Dr. Heaton, Dr. Mayne, Dr. P. Smith, Dr. Castle, Mr. Ikin, Mr. Reynolds, Mr. Baker, Mr. Scattergood, Mr. Wheelhouse, Leeds; Mr. Hemingway, Dewsbury; Mr. Hill, Knottingley; Mr. Hornby, Pocklington, Mr. W. Matterson, York.

Dr. CHADWICK, the President, then addressed the meeting as follows:—

GENTLEMEN,—I have to thank you, in the first place, for the complimentary and high honour which

you have conferred upon me by placing me in this chair; and to assure you that, in return for your kindness in so doing my best endeavours shall be exerted to render the year of my official tenure as successful as any of its predecessors. I cannot hope to equal the efficiency of the gentleman who this day vacates the office, and many others who have on former occasions occupied the post; but to none of them, I may venture to assert, am I inferior in the strong desire which I entertain of rendering these meetings efficient to the objects for which they were commenced; and I am induced to hope, from the communications which I believe are to be brought forward to-day, that the present meeting may prove as profitable and as interesting as any other previous annual assembly.

I have another preliminary duty to discharge, and that is to welcome those of you who come from a distance once more to Leeds. Whilst I am warranted in expecting that we shall offer you something of novelty on the present occasion, we still regard ourselves in the position of recipients, in a double sense—of yourselves as visitors, and also of the professional information you are willing to communicate. For, after all, gentlemen, this is the grand object we should ever have in view in thus meeting together,—to benefit each other by the mutual interchange of ideas. To this end may I venture to detain you from the more useful business of the day, by devoting the few minutes ordinarily given to the Presidential Address to a few desultory remarks.

The year that has passed over since our Sheffield meeting cannot, in any professional sense, be regarded as eventful. Ours is a profession rarely marked by the occurrence of convulsive or organic changes; yet it had well nigh proved so in regard to the first subject which I have to mention, and which for the past few years has formed the staple of many similar addresses.

During the present Parliamentary Session, the almost tedious subject of Medical Reform might, but for the occurrence of a remarkable political *contretemps*, have received its final quietus. The late Home Secretary, it is well known had given much attention to this subject; and had rendered himself, it is believed, thoroughly conversant with the wants and wishes, as well as the multifarious requirements of the profession; so that, had it continued his duty to deal with the measure emanating from the Council of our own Association, we might reasonably have anticipated a termination of this long-debated question. I speak, gentlemen, merely as a chronicler of passing events of professional interest, and not as one who has ever been sanguine as to the results of legislative interference with us; but I must admit that the propositions of our Central Council, which have formed the basis of the new Bill, and upon which we, as a Branch of the Association, have passed our general approbation, have unquestionably been more favourably received by the entire body of the profession than any previous proposal. It combines in its enactments all that, in my belief, can be effected by legislation in favour of the profession. It avoids all extreme, and therefore objectionable, interference with

the rights of the existing *strictly-professional* corporate bodies. It leaves the present professional distinctions intact, whilst it provides for the efficient education of all classes. It resorts as little as possible to pains and penalties for illegal practice, whilst it secures the legitimate practitioner all the protection the law can afford him, in the least objectionable manner, by an admirably devised system of registration. The measure, therefore, whether regarded as a positive or negative good, secures our approval; and had not the political event to which I have referred transpired—with which, however, *in this meeting*, except as it bears upon the matter now noticed, we have no concern—we might have attained, in the passing of this Bill and the simultaneous production of the new and liberal Charters of the Colleges of Physicians and Surgeons, that consummation we must all agree is so devoutly to be desired—the final settlement of Medical Reform. We must never, however, gentlemen, forget that the primary and most effectual element of Medical Reform is personal; and unless we all of us act on this belief, legislative enactments and corporate enfranchisement will alike prove futile. In justice to myself, however, it is right, before quitting this subject, that I observe, in reference to the Charter of the College of Physicians, as at present propounded, that it will, I apprehend, require some material alterations before it meets with the general approval of the provincial physicians.

Medicine is a progressive, and consequently, to a certain extent, an ever changing science; but the contrary is frequently urged against us, that we, as a profession, are so wedded to our fixed and antiquated notions, that we can neither admit nor tolerate anything that is new. This assertion, I maintain, is as calumnious as it is untrue, for I know no set of men more open to conviction, more ready to receive and investigate new propositions, than the members of our profession; indeed, as regards the trial of new remedial agents, and the admission of, and inquiry into, the value of proposed theoretical and practical improvements, the fault lies in the opposite direction, that we are often too open to admit as possibilities those things which too frequently disappoint our expectations. But when we are called upon, by those who thus assail us, to ignore the accumulated and growing experience of ages,—when we are required to subvert the principles upon which the noblest minds that from time to time have adorned our profession have based their conclusions,—and when we are expected to abandon the guidance of common sense, in admitting the crude and unphilosophical vagaries of any upstart theorist, the rational scepticism which, under these circumstances, we are justified in exercising is, I firmly believe, in the present day, the grand safeguard of our science. Not to dwell further upon this tempting topic, I would remind you of the dignified rebuke administered to the more glaring forms of empiricism, by the splendid resolutions of our Parent Association at its Brighton meeting.

In returning from this digression, I would attempt to illustrate, by a reference to a few of the more prominent topics of the day, that active spirit of investi-

gation, that eager inquiry after truth, which, I maintain, as distinctly characterises us as a profession in the present day, as at any other previous date.

Many important and laborious investigations, now conducted by the members of the Epidemiological Society, into the efficiency and true value of vaccination, as a preventive of small-pox, will, I am satisfied, lead to important practical results, and will, I trust, re-establish the professional and public confidence in this simple means, whether by prevention or modification, of diminishing the mortality of this once fatal malady. The stirring of this very important question suggests many grave reflections which time will not permit me to pursue. Knowing, as we do, the readiness with which the public omit all precautionary and preventive measures, unless the disease against which they should be adopted be actually at their door, and the aptitude with which they avail themselves of any doubt as to their efficiency, particularly when that doubt is propagated by the profession as an excuse for their own neglect, we cannot fail to regard the statements which have thrown a suspicion upon the efficiency of vaccination as most unwisely made, unless the evidence supporting them be better established than I am willing to admit. I contend, then, that the inquiry, by this important society, is fully justified by the circumstances of the case, and we owe to it, as a profession, a deep debt of gratitude for its spirited conduct in the matter.

The splendid application of Dr. Marshall Hall, of his truly philosophical views of the physiology and pathology of the nervous system, to the alleviation and possible cure, in some cases of epilepsy, claims at any rate our admiration; and, should farther experience confirm his statements, a great advance is unquestionably made in the management of this almost intractable disease.

The former discussions as to the nature of continued fever, and more particularly its supposed varieties, have recently been revived, and still occupy the attention of those members of the profession enjoying more extended opportunities for observation. A marked tendency has become apparent, at any rate in the London schools, to divide these forms of fever into several varieties, with the more important of which—typhus and typhoid, we have long been familiar. It is contended, that by many marked symptoms,—by a peculiar rash, almost invariable in its occurrence,—by a particular morbid condition of the mucous membrane of the intestines,—by its almost constant mode of origin and duration,—and by a vast variety of subsidiary phenomena, the form of continued fever, denominated typhoid, is distinguished, and at any period of its course distinguishable from another variety known as true typhus. This is said not to be so commonly marked by an eruption (which is of a different character when it does occur) to be free, or nearly free, from the peculiar intestinal morbid changes, and to have a different origin and course.

The result of my own experience in the observation and treatment of fever, has led me to very different conclusions. We constantly find in the fever hospital

in this town, that the ulceration of the mucous surface exists along with the dark-coloured rash of typhus, or with no rash at all,—that the typhoid rash occurs in cases where the mucous membrane is not affected,—that this condition is by no means necessarily marked by a diarrhoea,—that the two forms of eruption sometimes occur simultaneously in the same case,—and that, in every conceivable form, the symptoms said so strongly to mark the special forms of fever, are mixed together in the same individual. This active spirit of inquiry, the existence and operation of which I am thus attempting to prove as directed in the above channel, must eventually lead to an improved pathology and treatment of this very frequent disease.

I would claim, too, as efficient to my argument, the valuable results obtained from the analytical and microscopic investigations into the purity of various articles of food, of common consumption, so successfully promoted by the proprietors of the *Lancet*. Should these investigations, as I think has been promised, be carried on to the examination of drugs, and the consequent exposure of the adulterations to which they are subjected, a still more weighty obligation will be conferred upon the profession by the spirited conductors of that journal.

How rarely we find that the satisfactory results obtained from the first trial of any new remedy are realized in its continued employment. We must all of us have instances fresh in our remembrance illustrating this fact; and although the adulterations to which it may be subjected, as soon as it acquires popularity, will not alone account for the discrepancy, yet I am satisfied that not unfrequently they have much to do with its explanation. The general employment of the microscope in recent years, has aided materially in the improvement both of the science and art of medicine, and the zeal with which its revelations have been pursued, furnishes most important indices of the zealous activity of the professional mind, which, I am contending, still continues to operate. A reference to this instrument, however, becomes highly suggestive of a prudent caution in its use, lest it should be abused, as it is liable to be, by its too enthusiastic advocates and admirers, or to serve the purpose of unscrupulous empirics. Speaking of medicine in its double character, as a science and an art, I have no hesitation in affirming that the microscope is more really valuable in the study of the one than the practice of the other: in other words, the physiologist, the general anatomist, and the pathologist, will derive more aid from the use of the microscope than the practising physician, who, although he may be aided in his diagnosis, by the employment of this instrument, will not find it particularly suggestive of remedial measures. Far be it from me to decry or limit the employment of this instrument, when used with proper and strictly scientific intentions; all that I desire is, that it should be placed upon its proper footing—that it should be regarded merely as one of the many valuable adjuvants to the successful prosecution of our work. Instruments like this, have, I contend, like newly-introduced remedies, two severe

ordeals to undergo—first, the enthusiasm consequent upon the introduction; and, secondly, the temporary neglect following their early and indiscriminating popularity. The stethoscope has survived both these trials. The microscope and the speculum are still, in my opinion, contending with the first. Time warns me, however, that I must not detain you longer from the more instructing as well as more necessary duties of the day. I have said sufficient, at any rate, to establish my position, that, contrary to the statement of interested parties, we of the “old school” are still actuated by an active and willing spirit of improvement, and I trust that the reflections I have engrafted on each of the employed arguments for the purpose, may not prove destitute of interest.

Mr. W. MATTERSON, the Secretary, then read the

Report of the Council.

“Your Council, in presenting their Annual Report, would congratulate the Branch upon again revisiting Leeds, where so many of its members have always taken an active part in furthering its interests, and where so much has been done in elevating the character and rank of the Provincial Medical and Surgical Practitioner.

“The long and much-agitated question of Medical Reform, has again been brought forward by the Central Council at Worcester, who issued the draft of a bill for the consideration of the different branches, and at their request, as the members are aware, a special meeting was held at Leeds, at which the details of the proposed Bill were fully discussed. The meeting was of opinion that the Bill represented the principles previously entertained and advocated by the Branch, but that several modifications in its details were required. It is unnecessary to enter fully upon the alterations suggested at the meeting, as they have been already laid before the members in the journal of the Association. After receiving the different reports of the various Branches the Central Council conferred with the late Secretary of State, who expressed his readiness to assist them, and had fixed a day for that purpose, but a change of Administration rendered it impossible to introduce a Bill during the present session.

“The Central Council have, however, issued an amended Draft, which your Council earnestly recommend for your consideration. Some of the suggestions adopted at your special meeting have been introduced into the Bill—as for instance, the appointment of the Medical Council is vested in the Secretary of State, instead of the Apothecaries’ Company. Another important alteration is, that after the student shall have passed all the Examinations appointed by the General Licensing Board, and before taking advantage of his licence, he shall obtain the diploma either of the College of Physicians or that of the College of Surgeons. Upon the whole, the proposed changes are certainly a great improvement, and since the Colleges of Physicians and Surgeons necessarily exercise a considerable influence in any changes that may be made, it will be most conducive to our interests to make the best use of the materials offered by these two existing bodies.

“Your Council would also draw your attention to the contemplated changes in the Royal College of Physicians

The Draft of a Charter has already been issued, the object of which is to enable all physicians, from whatever College they may have derived their diploma, to become members of the College which is to be designated the Royal College of Physicians of England, and of which members will become fellows by examination or election.

"The College of Surgeons has now received a new Charter, identical with a Draft issued last year, by which, with some other important changes, the members of the College fairly entitled to the Fellowship are to receive it; surgeons are to be examined in midwifery, and provincial surgeons may henceforth enter the Council, but have not had conceded to them that which was held out to us,—the privilege of voting by proxy at the election of the Council; an omission which this Association cannot but regret. Imperfect as these changes may be, still your Council would view them as steps in the right direction, and would hope that ere long every member of the profession will enjoy that right and protection to which he is justly entitled.

The Council would suggest to the meeting the propriety of the expression of its general accordance with the admirable resolutions adopted at the Brighton meeting for the suppression of quackery, and its condemnation of those medical practitioners who pander to the popular delusions of the day.

"Your Council have pleasure in informing you that the Branch has increased in the number of its members, which now amount to 127; and in resigning their trust would urge upon you the necessity of a fuller attendance at its meetings, as nothing could more seriously impair its interests than the diminution of spirit consequent upon the falling off in the number of members attending its annual reunions, assured as it is that occasional exchanges of hospitalities, no less than interchanges of professional knowledge, tend to increase our sympathies for each other, and make us more useful to our fellow-creatures. In explanation of the deficiency of attendance it has been suggested that the time of meeting hitherto adopted interferes with the meeting of the parent Association and other kindred institutions. It will, therefore, be proposed that in future we shall hold our Anniversary during the first fortnight in May, which period we hope will be more convenient, and thereby secure a better attendance."

The following resolutions were then unanimously adopted:—

Moved by Dr. HEATON, seconded by Mr. HORNBY,—
"That the Report of the Council just read be received and adopted."

Moved by Dr. P. SMITH, seconded by Mr. HEMINGWAY,—
"That the following gentlemen be appointed the Branch Council for 1852-53:—Mr. J. Allen, H. S. Belcombe, M.D., Mr. B. Dodsworth, Mr. R. Hey, T. Simpson, M.D., Mr. C. W. Williams, Mr. W. D. Husband, Mr. W. Matterson, York; C. Chadwick, M.D., Mr. G. F. Garlick, Mr. W. Hey, Mr. T. P. Teale, Mr. T. Nunneley, Mr. S. Smith, Leeds; F. Branson, M.D., Mr. H. Jackson, M. De Bartolomè, Mr. W. Jackson, Mr. G. Turton, Mr. G. Reedal, Sheffield; T. Sandwith, M.D., Beverley; H. Y. Whytehead, M.D., Craike; Mr. J. Ness, Helmsley."

Moved by Mr. S. SMITH, seconded by Mr. GARLICK,—
"That Mr. W. Matterson be reappointed Secretary."

Moved by Mr. T. P. TEALE, seconded by Mr.

PRICE,—
"That the meeting of the Branch for 1853 be held at York, and that R. Hey, Esq., be the President-Elect."

Moved by Mr. GARLICK, and seconded by Mr. S. SMITH,—
"That in future the time of meeting be during the first fortnight in May."

Moved by Mr. NUNNELEY, seconded by Mr. S. HEY,—"That this meeting desires to express its general accordance with the admirable resolutions adopted at the Brighton meeting for the suppression of quackery, and its condemnation of the conduct of those medical practitioners who pander to the popular delusions of the day."

The following communications were then presented to the meeting:—

"Cases of Chronic Affections of the Stomach, accompanied with Vomited Matters in which Sarcinæ were Detected," by T. P. Teale, Esq. Illustrated by drawings and the microscope.

"On the Foramen Centrale of the Retina, &c.," by T. Nunneley, Esq. Illustrated by drawings.

"On Tracheotomy," by Samuel Hey, Esq.

This concluded the business of the meeting. Thanks to the President for his conduct in the chair were proposed and seconded, and carried unanimously.

The members then adjourned to the White Horse Hotel, where a most excellent dinner was provided and a pleasant evening spent, under the able Presidency of Dr. Chadwick.

NORTH WALES BRANCH.

THE annual meeting of the NORTH WALES BRANCH of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION took place on the 15th ultimo, at the National School, Conway. There were present—Dr. E. HUGHES, of Mold, President; Dr. Edwards, Benarth; Dr. O. Roberts, St. Asaph; Mr. H. Williams, Llansaintffraid; Mr. H. A. Roberts, Penrhyn Hospital; Mr. John Lloyd, Mr. D. K. Jones, Langeffni; Mr. D. Hughes, Bangor; Mr. J. W. Pring, Llandudno; Mr. G. T. Jones, Denbigh; Mr. Owen, Abergele; Mr. Salusbury, Conway; and Dr. Hughes, Rhyl.

Letters were received from Dr. Cumming, Dr. Edward Williams, Mr. H. Williams, of Llanrwst, &c., &c., regretting their inability to attend the meeting from urgent professional engagements.

THE PRESIDENT said he was sorry that they were deprived of the services of the retiring President, Dr. Lloyd Williams, and was sure that they would all join with him in sincere regret that illness was the cause of his absence. They were also deprived of the pleasure of offering their thanks to him for the very able and courteous manner in which he had presided at their last meeting. Might he soon be able to resume the duties of the profession in which for years he had served so eminently, and with such distinguished success. He knew this was the sincere and earnest wish of all who had the pleasure of his acquaintance, and of none more so than of those amongst them who were wont to recognize

his valuable services in consultation. Would he permit him to thank them for the honour which they had conferred upon him in electing him President, and allow him to assure them that it was ever his most anxious desire and endeavour to promote the honour of the profession, and further harmony and good feeling amongst its members. Such were some of the avowed purposes for which this Association had been established. Its other objects were so well known, that by recapitulating them he should only be repeating an oft-told and well-remembered tale. He would detain them but a short time while he briefly referred to those subjects which had specially engaged the attention of the medical profession since their last meeting. The prospect of Medical Reform, blighted by the adverse opinions as to its attainment which had confounded and set at naught the good intentions of Sir George Grey, in 1850, had again been revived, under the auspices of a Committee of their own Association. The proposed measure had been for some time made public; it had received great consideration, both from their own and other medical associations, and they were unanimous in recording their opinions that it was the best which had been submitted to them. At the coming anniversary at Oxford the Bill would be further discussed, and every means taken to forward it. The medical corporations had held silence so far on the matter, but it was to be feared that this was merely the precursor of a storm. It was hard to imagine how the medical colleges would allow duties to be thrust upon them, which it had long been in their power to have undertaken. The Apothecaries' Company, too, would not willingly resign functions which they had so long exercised, unless they were assured that the charge passed into equally efficient hands; however, they could only wish the measure good luck, and that these opposing parties, if they *should* turn out to be opponents, would be propitiated, and the Bill carried. While these matters were exciting the anxious interest of the profession, it was a great necessity that they should repudiate all connection with those members who deserted the truths of science for the mummeries of mesmerism, and the charlatanisms of homœopathy and hydropathy. He believed it would be found that of these, those who practised what was called homœopathy set forth the loftiest pretensions, and broached the greatest absurdities. Nobles and divines, good, and perhaps in other matters learned men, but whose knowledge of medicine appeared to be wonderfully akin to the skill of Falstaff's honour in surgery, had claimed for their imaginary doses superhuman perfection, and enforced their arguments in language as visionary as the principles they vindicated. How truly did this illustrate the remark of a lately-deceased physician:—"Talk of the gullibility of the lower orders of society, when listening to the harangues of political quacks! Their credulity is not half so great as that of their superiors, when swallowing the matchless absurdities of the most unprincipled charlatans." He trusted, however, that in no part of the day's proceedings they should be more unanimous than in recording their opinions of the matchless absurdities

of homœopathy. He then wished to draw their attention to a leading article in the last number of the *Journal* relative to a proposed notice of motion given by Dr. Cowan, of Reading, to the effect that the *Journal* should be hereafter printed and published in London, and issued once a week. The editor spoke of this as a great alteration, and invited all the members of the different Branches of the Provincial Medical and Surgical Association to duly consider the matter before coming to any determination. If any of them thought proper, it was quite possible for them to entertain the subject at their present meeting, and if they chose, to depute one of their members to attend the Oxford anniversary, shortly to be held, and there express their own views. He would now no longer detain them from the more important business of the meeting.

The annual report was then read by Mr. D. K. JONES, Llangejni, one of the Secretaries, as follows:—

"The Report of the affairs of the 'North-Wales Branch' may be briefly noticed. This Society is steadily advancing in the good opinion and support of the medical profession of the principality, and some new members have been added to our ranks since our last meeting. When we view the principles upon which our noble Institution is founded, and dwell upon the many advantages it affords, it gives us hope that ere long many more will enrol themselves under its banner.

"The state of the funds of this Society is—as it always must be—an important feature in the transaction of business. The expenses incurred in its establishment, and in conducting its proceedings up to the present time, have been defrayed by the usual allowance of one-seventh part of the guinea paid by each subscriber during the first year, which was sanctioned by the Council of the Parent Association, and by the kind and liberal donations received from many of the members. The balance in the Treasurer's hands is 12s. 1d., a sum inadequate to meet the demands."

Dr. EDWARDS proposed, and Mr. WILLIAMS seconded the adoption of the report. Agreed to.

Dr. ROBERTS proposed—

"That Dr. Peter Williams, of Holywell, be President-Elect for 1853, and that Holywell be the place of next anniversary."

Mr. OWEN, of Abergale, seconded the resolution, which was unanimously adopted.

Mr. G. T. JONES, of Denbigh, moved, seconded by Mr. D. Hughes, of Bangor,—

"That Dr. E. Williams, of Wrexham, Mr. D. Kent Jones, of Llangejni, Honorary Secretaries, and Mr. J. Lloyd, of Llangejni, Treasurer, be re-elected; and that the following gentlemen be named for the District Council for the next year:—Mr. T. T. Griffith, Wrexham; Dr. Roberts, St. Asaph; Dr. J. Roberts, Bangor; Mr. W. P. Jones, Holywell; Dr. Edwards, Benarth; and Mr. Hamilton A. Roberts, Brynmeurig, Bangor."

Mr. HAMILTON ROBERTS proposed—

"That the members of the 'North Wales Branch of the Provincial Medical and Surgical Association,' assembled at their annual meeting in Conway, having taken into consideration the 'Amended Draft Bill of Medical Reform,' as put forth and adopted by the Council of the Parent Association, do (with the exception of the 35th clause) approve of the measure as one more eminently calculated to heal the distracted state of the profession than any that has been hitherto proposed."

The motion was seconded by Mr. D. KENT JONES, and unanimously passed.

Dr. ROBERTS, of St. Asaph, moved—

"That this meeting considers that it is imperatively necessary that 'chemists and druggists' should be prohibited from pursuing counter practice, and visiting the sick and prescribing for them; that it is an anomaly which should be immediately and effectually put a stop to by a Legislative enactment; and that with this view, a more stringent clause be inserted in the "Amended Draft Bill of Medical Reform," than the one which is alluded to therein."

Mr. G. T. JONES, of Denbigh, seconded the resolution, which was adopted.

Mr. J. LLOYD, of Llangefni, moved—

"That it is the opinion of this meeting that the doctrines of 'Homœopathy' are based upon most erroneous and false data, and are propagated through ignorance and imposture. That the system of homœopathy is prejudicial to the cause of science, and dangerous to the public health; and that this meeting, therefore, considers that it is the imperative duty of all regularly-qualified members of the medical profession, on no account, directly, or indirectly, to meet *homœopathic* or other *irregular* practitioners in consultation."

The PRESIDENT had already referred to this subject, and to his remarks he had little to add. With reference to the latter part of the resolution, however, he had an observation to make. Besides homœopathsists it spoke of other irregular practitioners. He thought the terms of the resolution were such as seemed to include in its strictures a class of members of the profession who had commenced practice before the passing of the Apothecaries' Act. A few years ago in Liverpool there had been only one medical practitioner who was both a member of the College of Surgeons, and a Licentiate of Apothecaries' Hall. Since then the advancement of the science had been very rapid; and there were still many medical men whose only legal title to practise consisted in their having been members of the profession before the passing of the Act. [The President here explained that the resolution was not intended to have any reference at all to these parties.] With respect to homœopathy, he could not help making a few observations. He most heartily concurred in the remarks of the President on a system so utterly absurd. It was as much opposed to logic as it was to medical science, and equally belied the conclusions of ordinary reason as it did the universal results of professional experience. He was clearly of opinion that it formed a part of an attempt to begin to oppose the great and true doctrines of philosophy, on many points—matters connected with general science, as well as those specially relating to medicine. Even those scientific facts which had been demonstrated by Newton had been called in question. It was evident that parties figuring as patrons, who strongly recommended homœopathy, were endeavouring to oppose and controvert the very best established doctrines of philosophy. It behoved them all, as members of that Association, to set their faces not only against the innovations and ridiculous pretensions of homœopathsists, but against a set of men who had made up their minds to oppose everything great in science and philosophy.

Dr. HUGHES, of Rhyl, seconded the resolution.

Dr. EDWARDS said he begged to be allowed to make one or two observations on the subject which was before them; but after the able manner in which it had been alluded to by the President and the mover of the resolution, he would not long occupy their time. He did feel strongly on the subject of the mockeries and delusions of the day. He felt that it was a melancholy reflection that in the age in which they lived these doctrines should have obtained credit so extensively as they had. He did feel that it was one of the most melancholy views which the present aspect of society presented; and hoped and trusted that all of them would be determined to hold no intercourse whatever with those backsliding members of the profession; they were members of their body certainly, but they had gone out from them. If they were to countenance these men, either by meeting them in consultation, or in any other way, it would be wrong. Even if they were called in to assist in any case, they should rather decline all interference, unless the case was given up wholly to their management. It was in this way—by meeting these men in consultation—that the error had already spread so widely. It had been by their own lukewarmness, and their continued friendship and intercourse with the men who had embraced these fallacies, that the doctrine had obtained the standing which it had. They ought to have cast them off at once, and disclaimed all connection with them, as the physicians of Edinburgh had done, and in doing so set them a right example. He felt that it was impossible for any one of them to meet homœopathsists in consultation without tarnishing their individual character, and casting an odium on the profession. He was very glad that the subject had been brought before them, and felt that they should be only doing their duty in decisively recording their adverse opinion.

Mr. H. A. ROBERTS said he very strongly coincided with the remarks which had been made on homœopathy and other similar delusions. He thought that great blame attached to their own medical institutions for not more promptly and decisively publishing their estimate of them. Abroad, when any new doctrine was broached, there was always a public and authorized inquiry made as to its intrinsic merits. In such cases the Institute of France always appointed a properly qualified body of men as a commission of inquiry. The new professor had a certain number of patients in the hospital placed under his charge, and these men watched his operations upon them, and their effect. Such had been the case with homœopathy and other things, and the consequence was, that after an inquiry of this sort, and an adverse report, the system had died away there, and taken refuge in England, where but too many other delusive doctrines found a field of action.

Dr. EDWARDS proposed a vote of thanks to the retiring President, with sincere regret for the cause of his absence.—Passed unanimously.

The PRESIDENT said they had now completed their preliminary business, and should be glad to hear any papers or statements relating to medical science which any of them might be disposed to give.

Mr. H. A. ROBERTS said, that before proceeding further he wished to ask—Was it the general wish of the meeting that any medical or surgical papers which might be read, or cases which might be brought forward, should find publicity in the local papers? He certainly thought that discussions on purely medical and surgical topics should not go beyond themselves.

Mr. LLOYD said he was at a meeting of the Parent Association held two or three years ago at Derby, and their idea was that a slight sketch of the proceedings was not at all inappropriate. It appeared to him that they considered that these meetings were intended to interest the public generally in the profession, and that that was a proper mode of doing so. He did not think there was any great danger of unfit details being published, and as to a slight sketch he thought there could be no objection to such being given.

Dr. EDWARDS said there were so many objections, and those insuperable ones, to medical reports being published in the provincial newspapers, that he thought they should at once determine not to allow it to be done. It more became them that these matters should remain with the profession.

The subject then dropped for the time, and

Dr. EDWARDS originated a discussion on that portion of the President's Address relating to the proposal of Dr. Cowan, of Reading. He stated in his notice of motion "that the *Journal* be published weekly instead of fortnightly, and henceforth be edited, printed, and published in London." As a very old member of the Parent Association he had had an opportunity of feeling the pulse, as he might say, of the members generally with regard to the position of the Association. He could not but look at it in prospective as well as in its present state. Their great anxiety should be to extend their boundaries. He felt bound to state what he knew to be the very general feeling of the members, and also his own individual feeling on this matter,—it was, that they ought to have a journal, an organ of the Association, more worthy of them than they now had. Without at all disparaging the efforts of their friend at Worcester, no gentleman in the provinces could give that journal the value and position which it ought to have as the organ of the Provincial Medical and Surgical Association. He did know that the character of the *Journal* had, to a certain extent, a damaging effect upon them. He did not say that it was not what it could be as long as it was issued in Worcester, but it was not what it ought to be as their recognised organ. He thought it only fair that the editorial notice of Dr. Cowan's intended motion should be read at that meeting, as they were invited duly to consider the proposed alterations. [The speaker then read the leading article in the *Journal* which referred to this matter. In this the Editor maintained the advisability of allowing the affairs of the *Journal* to remain in their present state, rather than attempt any alteration.] He must say that he could not see any weight of argument in this article. There was a free admission that the change would be for the better, and the only question the Editor urged was, whether the funds of the Association could afford

to remove the *Journal* to London, and bring it out weekly instead of fortnightly. Now, when he maintained the propriety of these alterations, he cast no reflection whatever upon the gentlemen who now had the management of the *Journal*. It was all that it could be in their hands, but at the same time not that powerful organ of the Association which was to be desired.

Dr. O. ROBERTS, St. Asaph, said he felt a great objection to removing the *Journal* from Worcester. The fault of its not being so efficient an organ as it ought to be was not at Worcester, but with themselves. They were the parties to blame. The *Journal* was published for the purpose of affording an opportunity to the members of the Association of recording their experience in general practice, and if that opportunity were not taken advantage of, the members themselves were at fault. If the *Journal* was moved to London, it would no longer have the character of a provincial journal, but become a second or third-rate London journal.

Dr. EDWARDS said the *Journal* was first issued in London, and the leading articles sent up from Worcester. He was far from wishing to destroy the provincial character of the *Journal*, but he thought that that would not be at all lessened by its being published in London. He should not have said a word upon the subject, but he did know the effect which the *Journal* now had upon them, and the general opinion with regard to it. He felt extremely interested in the efficiency and progress of the Association, and he thought nothing would tend more to promote this than the proposed change in the publication of their organ.

The PRESIDENT said he was glad they happened to differ on the subject, as then the arguments on both sides would probably be brought forward. Whatever might be the opinion as to the desirability of removing the *Journal* from its present place of publication, and issuing it oftener, there was a very general complaint that it was not what it ought to be. The discussion of this matter at the general meeting would, he hoped, result in improvement one way or other. At any rate the present notice at Worcester would have the effect of making them do their best there.

Mr. LLOYD said, unless there was some chance of improving the *Journal* by the alteration of its place and time of publication, he felt strongly inclined to allow it to remain as at present. He thought the removal to London would be altering the character of the *Journal* and making it a metropolitan instead of a provincial publication; though if they chose they might certainly alter its title at the same time, and call it the *London and Provincial Journal*.

Mr. H. A. ROBERTS said, as to altering the title of the *Journal*, there would be no necessity for that, as the removal to London would not affect its character as a provincial journal in the least. It might be printed at London or Worcester, or any where else, and still be a provincial journal—the organ of the Provincial Association.

The subject then dropped.

The meeting then proceeded to the discussion of professional topics, the reading of cases, &c., and was so occupied the remainder of the afternoon.

Mr. Robert Jones, of Carnarvon, sent a preparation of "Intussusceptio" for the meeting. It was taken from a man who was attacked with severe pain in the abdomen after having taken a dose of Pulv. Rhei, which operated inefficiently, and from which time he had no alvine evacuation. He lived for about ten days, having had stercoraceous vomiting for many days. The lower part of the ileum was invaginated into the caput coli. There was considerable inflammation of the lower part of the ileum, for about six inches of its length, but none elsewhere. The man had been leeches and had taken a considerable quantity of calomel and opium.

Mr. Hamilton A. Roberts read a "Case of severe Injury of the Elbow-Joint, where portions of Humerus and Radius were divided by a large Chaff-cutting Engine." The patient was a lad about 17, and the case was successfully treated without amputation. The bones were shown to the meeting and handed round for inspection. Further particulars of this interesting case will be found in the *Lancet* for January 27th, 1849.

Mr. Lloyd, of Llangefni, communicated a "Case of Purpura."

Dr. Hughes, of Rhyl, also related a "Case of Purpura."

Dr. EDWARDS, of Benarth, moved a vote of thanks to the worthy President for his very excellent address and conduct in the chair, which was carried with acclamation.

At five o'clock the members of the Association adjourned to the Castle Hotel, to partake of

THE DINNER

which had been there provided for them. Here they were joined by the Rev. Mr. Morgan, Vicar of Conway; Dr. John Roberts of Bangor; and Mr. Jones of Carnarvon. Dr. Hughes, of Mold, President; Mr. D. Kent Jones, Llangefni, Vice-President. The repast was everything that could be desired and was done ample justice to by the guests.

On the removal of the cloth,—“The Queen,” and “Prince Albert and the rest of the Royal Family” were proposed from the chair.

The PRESIDENT then gave—"The Bishop and Clergy of the Diocese," connecting with the toast the name of their guest, the Vicar of Conway. Their respective professions were frequently associated, and no class of men could bear higher testimony to the zeal, assiduity, and fearlessness the clergy evinced in the performance of their various duties than the medical profession. He begged also at the same time to thank Mr. Morgan for the use of the National School, and he wished they could have filled it better.

The Rev. Mr. MORGAN said, they—the medical profession and clergymen, were frequently called upon to meet on sad and solemn occasions, and therefore he was all the more gratified to join them on this pleasant

occasion—a meeting, allow him to say, not only for social and convivial enjoyment, much as they might delight to attend, but productive of permanently beneficial consequences; inasmuch as by holding friendly intercourse with one another on matters connected with their profession, and frankly conversing together, they not only advanced the progress of medical science, but in the same degree in which they did that, contributed to diminish the amount of pain and suffering around them. Perhaps they would allow him to observe that there was only one cloud which cast a shadow over that meeting. In saying this they would at once anticipate that he referred to the absence of their retiring President and Mr. Hope Jones, a very respectable practitioner, he need not say, but also well known for his habits of the greatest benevolence and highest moral worth, always the first to suggest, and the most active to carry out any measure for the physical and moral improvement of the neighbourhood in which he lived. The loss to him of Mr. Jones's co-operation was great at the present time. Might it please God—whom he did not hesitate to name in that assembly—to bless and reward him for his efforts. And now he most heartily thanked them, in the name of the bishop and clergy, and begged to drink the health and prosperity of them all. They were frequently called upon to meet in the exercise of their several duties, and none could so well appreciate the advantage of co-operating with good professional men, as clergymen. He considered that their profession and his own were inseparably connected. It was too often their lot to meet in cases which were more fitted to the care of a medical man than of a clergyman, and which the latter was not called upon to attend through any appreciation on the part of the sufferer of the fundamental principles of religion—cases which were much better suited to the physician of the body, than to the physician of the soul. He begged to drink to their very good healths, and that they all might experience that solid satisfaction which only a faithful discharge of their duties would carry home to their hearts.

The PRESIDENT said, having now disposed of the toasts, which on all festive occasions they delighted to honour, he came to that which more immediately applied to the events of the day. Twenty years ago the founder of their institution and about twenty other gentlemen met at Worcester, to try to connect in one bond of union the disjointed members of the medical profession scattered throughout the provinces, and give them that influence to which singly it was impossible for them to attain. It was a matter of great congratulation that an association of so much consequence had been formed,—one which had offered to legislate on one of the most difficult matters connected with the profession, namely, Medical Reform, and in which every important and useful measure had hitherto failed, through the different views of professors. This was the case in 1850. He begged to give "Success to the Provincial Medical and Surgical Association," and to couple with the toast the name of its distinguished founder, "Sir Charles Hastings, with every good wish that he may live long to enjoy the title conferred on him by Royalty, the honours which learned men were about to bestow upon him, and what, he doubted not, would be treasured by

him more than either, the high esteem in which he was held by his professional brethren."

The PRESIDENT said he had now to propose a toast which was particularly interesting to themselves, and was in fact their own healths,—“Success to the North Wales Branch of the Provincial Medical and Surgical Association.” He only wished he could congratulate them on a better attendance; but they all knew that medical men were often called upon to fulfil duties of which they could have no previous intimation, and which imperatively demanded their immediate attention. And he was sure there were some friends absent to-day whom it would have taken a great deal to keep away, and therefore they must not look upon that paucity of their number as any indication of the decline of the Association. This Association had already been productive of great good, as it had brought its members into more courteous and familiar intercourse than would otherwise have subsisted between them. He had great pleasure in welcoming the new members which had joined them since their last annual meeting. There were still other members of the profession of no mean standing in North Wales, who held aloof from them; he trusted, however, that a good time was coming when they also would attend their gatherings, and see that they were not only festive meetings, but meetings held for the purposes of mutual instruction, and in which individual members might ask the advice of their more experienced brethren on cases which might come under their notice. He connected this toast with that of a gentleman who was prevented from being there that day,—the first President, Mr. Griffiths, of Wrexham, of whom they might all be proud.

Dr. EDWARDS said, it devolved upon him to propose a toast which could not precisely be pronounced with decorum from the chair, and having made this remark, they would all understand to what he referred. When the President proposed “Prosperity to the North Wales Branch of the Association,” he waited to see whether he would sit down without uniting that toast with the name of any individual. Had he not done so, however, he was prepared to rise and propose a rider to that toast, namely, the health of the President himself, but as he had not an opportunity of doing so, he had greater pleasure in proposing the President’s health in this way. A more valued friend, and a more honest practitioner, did not exist. He must avail himself of that opportunity of thanking the President for the able and excellent address with which he had opened their meeting that day.

The PRESIDENT said, he assured them that it was his most anxious wish to stand well with the whole body of professional men. He believed that from their increased intercourse and improved knowledge, resulting from their being members of this Association, there would be daily less and less of those petty jealousies which had disgraced the profession, and disgusted its members. He thanked them for the compliment, and at the same time for the attention with which they had listened to the address which he had the great privilege of delivering to them in the morning.

Mr. R. JONES, Carnarvon, proposed the health of Dr. Lloyd Williams, much regretting the great affliction which he laboured under.

The PRESIDENT proposed the health of the President-Elect for 1853. Might they have a jolly good meeting under his Presidency.

Dr. WILLIAMS responded to the toast.

The PRESIDENT proposed the health of the Honorary Secretaries, and Mr. Lloyd, the Treasurer.

Mr. D. K. JONES, Vice-President, said, as one of the Secretaries, he begged to return them his sincere thanks, and much regretted that his colleague was absent, though he knew his heart was with them. He assured them that any small services which they (the Secretaries) could render, always were and always would be done with very great pleasure. He was sorry that there were so few present, but he hoped for better things at their next meeting. They had heard that day, and with very much gratification, the relation of some extremely interesting cases connected with the medical profession, and to the gentlemen who had communicated them they were greatly indebted; but he wished more particularly to propose the healths of the new members, Mr. H. A. Roberts, Dr. Hughes, of Rhyl, Mr. Salusbury, and M. R. Jones, and, with the President’s permission, he gave this toast.

The gentlemen whose healths were drank severally responded.

Mr. LLOYD proposed the health of Mr. H. Williams, of Llansainffraid, who acknowledged the compliment.

Mr. SALUSBURY proposed the health of Dr. Edwards of Benarth.

Dr. EDWARDS, in responding, observed that he had been sometimes the sole representative of this district in the annual meetings of the Parent Association, but as several of them had promised to accompany him next time, he hoped he should not be so again. He was one of the oldest members of the Parent Association, and he thought he might say one of its most constant attendants, but he had never attended one of their meetings without being amply compensated for his expense and loss of time.

The PRESIDENT next proposed the health of Dr. John Roberts, a gentleman who had been very instrumental in originating the North Wales Branch of the Association.

Dr. J. ROBERTS, of Bangor, in replying, expressed his regret that an accident had prevented his attendance at the morning meeting, and proposed the health of Mr. R. Jones, of Carnarvon.

Mr. R. JONES responded, and proposed the health of Dr. Owen Roberts, of St. Asaph.

Dr. O. ROBERTS, of St. Asaph, replied, and proposed the health of Mr. Owen, of Abergele.

Mr. OWEN acknowledged the compliment.

Mr. SALUSBURY proposed “The Press,” which was acknowledged by the representative of the *North Wales Chronicle*.

Dr. O. ROBERTS, of St. Asaph, proposed the health of Mr. Jones, of the North Wales Lunatic Asylum.

Mr. JONES responded.

The PRESIDENT proposed the health of their President two years ago, Dr. Cumming, one of the oldest medical men in North Wales.

Mr. JONES (North Wales Lunatic Asylum) proposed the health of Mr. Hughes, of Mold, the father of their President that day.

The PRESIDENT, on behalf of his father, acknowledged the compliment.

Dr. EDWARDS proposed the health of Mr. Hope Jones, of Conway.

Mr. SALUSBURY thought it incumbent upon him to respond on behalf of his very kind partner, and at the same time to testify his gratitude for the kind introduction which Mr. Jones had given him in that neighbourhood.

Mr. WILLIAMS, Llansantffraid proposed the health of Mr. Pring.

Dr. O. ROBERTS, of St. Asaph, gave "their next merry meeting."

The members then separated.

CAMBRIDGE & HUNTINGDON BRANCH.

G. L. GIRLING, ESQ., IN THE CHAIR.

MEETING OF THE CAMBRIDGE AND HUNTINGDON BRANCH, AT ST. IVES, JUNE 16, 1852.

Obstruction of the Bowels.

Dr. WEBSTER, of Cambridge, read an instructive paper on this subject containing the abstract of cases furnished him by members of the Association, and drew conclusions as to the causes and treatment of the affection. He reprobated strongly the indiscriminate and careless exhibition of purgatives, and said that the cases in which operative proceeding could be resorted to with a prospect of success, were very few and very difficult to distinguish, it being usually very hard to ascertain the seat and nature of the stricture. Often it is of a spasmodic nature, and yields, even in cases apparently desperate, to opiates and enemata, which should be exhibited slowly, and with care. This was well illustrated by an interesting case furnished by Mr. Few, of Ramsey. It had been supposed by some writers that an inference as to the seat of the stricture might be drawn from the quantity of urine passed, which would be small in proportion as the obstruction was near the stomach. His cases did not corroborate this opinion. In one of the cases the history of symptoms extended only to three weeks, the patient having been reported quite well till attacked with ordinary symptoms of obstruction of the bowels, following a slight attack of diarrhoea, yet a *post-mortem* examination revealed a cancerous stricture of the ascending colon, which disease had doubtless existed for some months. In another case, where the same disease existed, the nature and seat of the affection had been inferred with tolerable certainty from the symptoms which preceded the fatal obstruction. He exhibited a specimen of deficiency of small intestines, the canal terminating in a cul de sac at the first part of the duodenum. The great intestine contained brownish matter unlike meconium; this was taken from an infant who rejected its food, had no action of the bowels, and lived only two days, during which time urine was passed freely.

Mr. HUMPHRY mentioned two specimens in the

museum at Cambridge, of congenital imperforate condition of the duodenum. He did not find that that part of the intestinal canal was considered by pathologists to be especially liable to this imperfection of development, nor was he aware of any peculiarity in its mode of formation that would be likely to render it so. He believed that strictures (intrinsic strictures) of the intestinal canal which produce serious obstruction, are almost invariably cancerous, and the propriety of an operation for artificial anus is, under such circumstances, questionable, even when the seat of the disease is ascertained to be favourable, though the urgent sufferings of the patient may perhaps sometimes warrant the attempt to afford relief in this way. The cases in which an operation can be successfully attempted for the relief of extrinsic stricture, by dividing constricting bands, &c., must be very few, the difficulty of forming a sufficiently accurate diagnosis is so great; and the distended softened condition of the bowels above the stricture must add much to the hazard of the proceeding.

Cases and observations in confirmation of the views of Dr. Webster, were offered by Dr. Ward, Mr. Sayle, Mr. Crisp, and Mr. Foster.

Mr. FOSTER, of Huntingdon, related a case of "Unilateral Anasarca." E. N., aged 49. Left side weak from birth. Two years ago swelling, stiffness of left hand, without discoloration; swelling extended to the shoulder, then appeared in the left thigh and leg. No albumen in the urine, or signs of diseased heart. A year ago health began to fail, swelling increased, and induration of left subclavian glands and mamma were perceived. The case was considered well nigh unique by all the physicians and surgeons who saw the patient. A few days before death the right leg swelled, and fluid was detected in the peritoneal cavity. On *post-mortem* examination a scirrroid condition of the left breast was found. A scirrroid gland implicated, and by its pressure nearly obliterated the left axillary vein. Peritoneum in pelvis thickened, and studded with millet-seed-like tubercles. Adhesions about the left lateral ligaments and side of the pelvis. Enlargement of ovaries. No decided obstruction in the veins of the left lower extremity in any one part, though they were subject to general pressure in the iliac region.

Mr. FOSTER read a case of "Fracture of the Clavicle near its External End, and Injury to a Goitre, causing extreme Difficulty of Breathing, with Croupy Inspiration, sense of Choking, and Difficulty of Swallowing." These severe symptoms were supposed to be caused by extravasation of blood consequent on some laceration of the very vascular tissue of the goitre. Gradually the swelling subsided, the severe symptoms were mitigated, and the patient recovered.

Mr. FOSTER also related two cases of "Vitiligoidea;" Mr. PECK, of Newmarket, related a case of "Injury to the Heart by a Needle" (published at page 336); and Dr. WARD related a case of "Popliteal Aneurism, Cured by Pressure," which will be published in a future number of the *Journal*.

Nævus.

Mr. HUMPHRY made a communication on the result in cases of congenital vascular nævus where the disease has not been treated. This communication embodied the information furnished him by several members in answer to a query circulated among them. He found little bearing upon this question in surgical books, and many persons of large experience had been unable to give him information, he therefore gladly embraced the present opportunity of collecting facts. There is a man in Cambridge with vascular nævus involving the whole thickness of a considerable portion of the left cheek, causing a good deal of swelling, and most unsightly appearance; this had existed at birth, and had increased at any rate since his childhood only *pari passu* with his growth. In this case, therefore, the disease arrived at a certain point, and then became stationary. Five years ago there was a child in Addenbrooke's Hospital with venous nævus beneath both internal malleoli, besides a diffused nævous state of the skin of the soles of both feet and the left side of the scrotum. In the latter situations the disease looked not unlike varicose veins, and illustrated admirably the true nature of nævus, which consists in a dilated or hypertrophied condition of the small vessels, of a part cutaneous or subcutaneous, as the case may be.* The disease was too extensive to treat by any radical means, and was therefore left to take its course. The lad had been sent to the meeting that members should have an opportunity of examining the disease. It had advanced somewhat since he left the hospital. In this case, therefore, nævi left to themselves are making slow progress; they do not interfere with the lad's movements or enjoyments. Mr. Isaacson, of Huntingdon, had communicated the case of a little boy, now five years old—a nævus on the scalp increased up to the age of two years, and having been left alone entirely disappeared. Mr. Rix, of St. Neots, wrote word that cases of nævus which he had seen left alone had done well. Mr. Few, of Ramsey, used to extirpate all nævi, but what he had seen lately had induced him to alter his opinion with regard to the necessity of such procedure. In three cases where the parents refused him permission to treat the disease, it is either gone, or is gradually disappearing. Mr. Leigh, of St. Ives, furnished another similar case. Mr. Reid, of Canterbury, had seen two cases of severe subcutaneous nævus, in which a cure had followed the employment of means so little proportionate to the extent of the disease, that he was inclined to attribute the favourable termination in part at least to some spontaneous curative process. Inquiries made of a very great number of persons had failed to elicit a single case in which common untreated nævus had proved fatal. Just before the meeting Mr. Humphry had seen a paper upon this subject in the seventh volume of "Guy's Hospital Reports," by Mr. Birkett, in which five cases (three quoted from Vidal, and one furnished by Mr. Taylor, of Guildford,)

were related of spontaneous atrophy of nævus. Quite sufficient information had been thus collected to warrant the conclusion that a great number of vascular nævi, if left to themselves, will, in course of time, disappear. Some increase for a time, and then disappear; some increase for a time, and then remain stationary. Mr. Humphry had met with no evidence that they go on increasing to a fatal termination, though he was quite prepared to learn that such is the occasional result. That it is not so more commonly probably depends upon the fact, that in the greater number of instances the disease is cured by timely treatment. These remarks were not intended to apply to the disease called aneurism by anastomosis, which, commencing at some period after birth, is active in its progress, and if not arrested, is liable to bleed, and kill the patient. Dr. Ward and Mr. Isaacson furnished an interesting case of this kind. The disease was seated beneath the scalp in a young woman, and was at first supposed to be a cyst. A lancet had been thrust into it before the patient came under their care. They applied pressure well, and long-continued, without avail. Subsequently she was in St. George's Hospital, where it was decided on consultation that no operation should be performed. The tumour increased, she went home, and died.

A specimen of Dislocated Knee was exhibited, in which the crucial ligaments were torn; the lateral ligaments remained entire. The tibia was thrown quite forwards upon the condyles of the femur. It was easily reduced, and was going on well, there being no great swelling; but mortification of the foot and leg ensued, and amputation was performed by Mr. Lesturgeon, in Addenbrooke's Hospital, a month after the accident. Dissection showed that the popliteal artery and vein had been torn across; the divided ends were plugged, and healed.

Mr. EVANS, of St. Neots, showed a calculus which he had extracted from an oval fistula. It appeared to have as its nucleus a pebble, which had become slowly encrusted with feculent matter, forming a sort of hard shell over it.

SUFFOLK BRANCH.

The ninth anniversary meeting of the SUFFOLK BRANCH of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION was held on the 25th of June, at Needham Market. The general attendance was not quite so numerous as usual, which was partially accounted for in the letters of several of the absentees by the attractions of the approaching meeting at Oxford. Many of the members who felt compelled to abridge the scanty relaxation they allow themselves from laborious duties, could not attend both meetings, and we trust that the reservation which limited the number of attendants here, will tend to increase it with efficiency there.

The following members were present:—Dr. Ranking, Norwich; Dr. Durrant, Dr. Chevallier, Ipswich; Dr.

* See "Lectures on Surgery" by Mr. Humphry in this journal for 1850, p. 202, *et seq.*

Robert Growse, Esq., John Growse, Esq., Hadleigh; Dr. Bedingfield, Henry Beck, Esq., James Pennington, Esq., Needham Market; R. Martin, Esq., Holbrook; Wm. Jeaffreson, Esq., Framlingham; Dr. Kirkman, William P. Kirkman, Esq., Melton; William Ebdon, Esq., Haughley.

W. JEAFFRESON, Esq., of Framlingham, before resigning the chair, made a few observations on some of the events of the past year in connection with his Presidency, and on the tendency which these annual meetings have to promote courteous and gentlemanly conduct from member to member, and to cement those professional and social ties which have bound the general body together.

The chair was then taken by the President, Dr. BEDINGFIELD, who spoke as follows:—

Gentlemen,—I cannot take possession of the chair to which you have done me the honour to appoint me without some feeling of regret. I regret, that in order to make room for me, it has been vacated by one who has filled it so worthily, so wisely, and so well; and I regret, also, my own inability to perform its duties in the efficient manner they have hitherto been discharged. These regrets, however, are blended with much pleasure and satisfaction, for it does truly afford me both pleasure and satisfaction to meet my professional brethren upon this occasion, and to bid them, both individually, as well as collectively, a hearty welcome to Needham Market—to Needham Market, the place of my birth—a place endeared to me by many early recollections. It was here that, under the auspices of my uncle, the late Mr. Beck, one of the most indefatigable, as well as one of the most successful practitioners I ever knew, that I commenced my professional career; and it is here, should it so please my God, that I wish to bring it to a close. The time embraced between these two periods is now just half a century. Alas! how little have I accomplished: not only morally but professionally speaking. How many things have I done that I ought not to have done; and how many things have I left undone that I ought to have done. Were it not for this reflection, to day would be indeed to me a day of jubilee. But, notwithstanding these short-comings and backslidings, I sometimes flatter myself that the mites which I have from time to time thrown into the treasury of medical literature, may not have been scattered there in vain. We are told that the grain of mustard seed became a mighty tree; and we are told that bread cast upon the waters returneth after many days; and, although “hope deferred often maketh the heart sick,” I patiently and cheerfully “bide my time.” Nay, is not that time already come? Is not the establishment of Medical Provincial Associations a great and accomplished fact? It was in the year 1826 that I first proposed and advocated the formation of such Associations, and under the most discouraging circumstances, through evil report and good report, I continued that advocacy until they became established throughout the length and the breadth of the land; and to day I have had the high gratification to receive the Council of our Association beneath my own roof, and

in my own native town. This is indeed, Gentlemen, a rich reward; but I must abstain from self-gratulation, and without further loss of time, call your attention to the business of the day.

I believe it is usual in the first place to read the apologetic letters of the gentlemen who are prevented by other engagements from favouring us with their presence. These, I am sorry to say, are rather numerous; we have, however, no alternative but to accept the will for the deed. Their absence is, I doubt not, a source of mental regret.

I had hoped, Gentlemen, to have had the pleasure to introduce to you a friend of mine from Birmingham, who had given me reason to expect that he would do us the favour to come over and deliver a lecture on the construction and management of the microscope; an instrument which is daily unveiling to us the marvels of Nature and the mysteries of disease; an instrument, a thorough acquaintance with which is become an essential part of medical education. The stethoscope and the microscope have already achieved wonders, and they will continue to add to our knowledge, and to our successful treatment of “all the ills that flesh is heir to.” We shall, in the second place, proceed to the hearing and discussion of the papers which some of our members have been so kind as to prepare for our consideration. Upon this I shall only observe, that our time for this purpose is very limited; and as brevity is said to be the soul of wit, and as the power of steam is increased by compression, so may a little condensation or compression of the details of some of the cases and papers, be attended with its advantages. This, however, is a mere hint, which I leave to the discretion or good taste of the authors of the papers to avail themselves of or not, as they may deem advisable.

In the course of our proceedings the subjects of Medical Reform, of homœopathy, and of vaccination, may fall under review.

With regard to Medical Reform, I have been its zealous and straightforward advocate from my youth up until now. One of the objects which I have kept constantly in view, has been the strengthening and tightening those bonds of unity between the physician and the general practitioner, which, unhappily for the interests of both parties, have been so long impaired and loosened. To enter into a statement of the causes of this estrangement would occupy more time than can be spared; but I cannot help feeling apprehensive that the measures of Medical Reform which are now contemplated have a tendency to widen the breach between the physician and the general practitioner; and that, unless some vigorous remonstrance or demonstration be made, they will terminate in the abasement of the general practitioner, and the exaltation of the druggist. The general practitioner will, in fact, become a non-entity; the druggist the apothecary. I think I am borne out in this feeling by a letter of my friend, Dr. Webster, of Dulwich, which appeared a short time ago in our journal, as well as in the *Lancet*. But for circumstances over which we have no control Dr. Webster would have been here to-day to explain his

views. With your permission I will read some parts of a letter which I received from him on the subject. He writes,—

"I do wish that, in addition to what you intend to say so well and so truly on the subject of medical affairs, you would allude to the *Pharmacy Bill*, and also get up a resolution and a petition against it in the House of Lords. I am sorry to say, that though I have been able to raise a strong opposition to the measure, almost single-handed, and though it has been considerably amended, yet it passed the Commons yesterday morning (the 18th) at two o'clock, without a clause to prevent chemists practising. You may commend or censure me as you think proper; but pray do move in the question, for the Bill is fraught with the greatest danger to the public health, and with great injury to the general practitioner. Petition the Lords; there is no time to be lost."

With regard to homœopathy, that *ignis fatuus*, set afloat by knaves and simpletons, and which the fatuitous so eagerly pursue, I am of opinion that it would have been advisable to have allowed it to extinguish itself in the quagmire, or rather quack-mire, of its own absurdity. The opposition it has met with has given to it a temporary notoriety and importance which it would never otherwise have attained. We may, however, console ourselves with the assurance that it is concocted of such *perilous stuff* that it will not be much longer tolerated. Why, the ingredients thrown into their cauldron by the three weird sisters formed a scientific and comprehensible compound, in comparison with the drivellings, and the drippings, and the droppings, and the ass's sugar, and the ass's milk, of the homœopathists. I would seriously recommend "these devisers of cunning fables" to introduce these respectable old ladies' ingredients into their pharmacopœia:—

"Eye of newt, and toe of frog,
Wool of bat, and tongue of dog;
Liver of blaspheming Jew,
Gall of goat, and slips of yew;
Witch's mummy, maw and gulph;

But more especially,—

"Finger of birth-strangled babe,
Ditch-deliver'd by a drab,
Add thereto a tiger's chauldron,"

Would form a very valuable addition to their infinitesimal doses.

My faith in the preventive power of vaccination remains unshaken; and I still adhere to the sentiment expressed in my "Compendium of Medical Practice," some thirty-seven years ago, that, despite the baneful combination of ignorance, prejudice, and self-interest, the time will arrive when the name of Jenner "will be pronounced with rapture by a grateful world." Gentlemen, I would rather have been Dr. Jenner than the Duke of Wellington. The Duke has slain his thousands; the Doctor has saved his tens of thousands. How much more noble—how much more glorious, is it to preserve life than to destroy!

I had prepared a paper on the subject of vaccination, which it was my intention to have submitted to this meeting; but I was requested by Dr. Baird, (whose absence on this occasion, but more especially his removal from this neighbourhood, is very generally regretted,) to send it to the Epidemiological Society.

Anything worthy of remark it may chance to contain will probably be placed before the public by that highly-important and most valuable Association.

Before I conclude my observations, which I dare say many of my auditors are by this time of opinion might have been advantageously subjected to the *condensing* process I have already recommended, there is one circumstance to which I wish to advert, namely,—our want of Representatives, both as a profession and a provincial Association, in the House of Parliament. Without representation we shall never attain that rank, that *status* in society, to which our education, our talent, and our vast importance to the well-being of the community at large, so richly entitle us. Gentlemen, I first called your attention to this desideratum in 1834, in my address delivered in the Town Hall, Ipswich; and I have repeatedly recurred to the subject since that period. It has recently met with several able advocates; and I still hope to see the interests of our profession fully and fairly represented in a British House of Commons.

Letters expressive of regret at their inability to attend the meeting, were then read by the Secretary, from Mr. Williams, of Southwold; Mr. King, of Hartest; Mr. Lock, of Debenham; Mr. Mudd, of Hadleigh; Mr. Carley, of Laxfield; Mr. Marshall, of Woodbridge; Mr. Gross, of Earl Soham; Mr. Gorham, of Aldborough; Mr. Hammond, Mr. Bullen, and Mr. Bartlett, of Ipswich; Mr. Crowfoot, of Beccles; Mr. Read, (with the withdrawal of his name from the Association,) and from Mr. Bree, of Stowmarket.

On the mention of the name of Mr. Bree, the thanks of the Council and members were expressed for his able and energetic services as Secretary to the Suffolk Branch since its formation, with the conveyance of their assurances to him of the high sense they must ever entertain of his long-continued labours for its welfare.

The new members received were Mr. John Mitford Ling, of Saxmundham, on the nomination of Mr. Jeaffreson; and Mr. William Phillips Kirkman, by Dr. Durrant. The Secretary made a very satisfactory statement in regard to the Benevolent Fund. He said he had received several promises of an increased amount to former subscriptions, and he endeavoured to urge its peculiar claims on every member of the Association. This fund, he observed, was an integral part of the Association, and its appeal is made on the principles of *unmixed* benevolence. It has nothing for the encouragement of the giver of a *showy* character; and its supporters, whose names so liberally appeared lately in the pages of the *Journal*, have a register in a higher court than any of mere human approval—a register of the names of men who *literally* give, "hoping for *nothing* again."

The following papers were read, several of them eliciting most interesting and profitable discussions:—

"On the Efficacy of the Tinct. Ferri Sesqui-Chloridi in the Treatment of Erysipelas," by Dr. Ranking. Several similar cases were referred to in the discussion,

in which the iron was given in smaller doses than Dr. Ranking stated, and apparently with success.

"On Calculary Deposits in the Excretory Ducts of the Sublingual Glands," by Robert Martin, Esq. The case excited great interest. The calculi removed were shown.

"An Extensive Injury of the Knee-Joint," by Robert Martin, Esq. An interesting case. The patient was kindly brought over for the inspection of the members.

"A Case of Puerperal Convulsions," by Robert Martin, Esq.

"On a Variety of Latent Pneumonia," (in which he specially deprecated the use of the lancet,) by Dr. Durrant.

"A Case of Hay Fever," (from which he is himself the annual sufferer,) by Mr. W. P. Kirkman.

"A Case of Inversio Uteri, (read by the Secretary,) by Mr. Marshall.

The following resolutions were unanimously passed:—

Proposed by Dr. RANKING, seconded by Dr. DURRANT:—"That the place of annual meeting of the Suffolk Branch of the Provincial Medical and Surgical Association for the year 1853 be in Ipswich, and that Robert Martin, Esq., be requested to preside."

Proposed by Dr. ROBERT GROWSE, seconded by JOHN GROWSE, Esq.:—"That the best thanks of this meeting be presented to those gentlemen whose instructive papers and interesting cases have been read."

Proposed by ROBERT MARTIN, Esq., seconded by Dr. CHEVALLIER:—"That the regret of this meeting be conveyed to Dr. Baird, on the loss that this Branch has sustained by the removal of so valued an associate from Ipswich, and that their best wishes be expressed for his future professional and domestic welfare in his new abode."

Proposed by Dr. KIRKMAN, seconded by WILLIAM JEAFFRESON, Esq.:—"That this meeting is anxious to convey their united sentiments and wishes that the Editorship and Publication of the *Provincial Medical and Surgical Journal* be continued under its present arrangements, to which their entire concurrence is unreservedly given."

A vote of thanks was proposed to the President, Dr. Bedingfield, and the meeting separated.

The members dined together at the Swan Inn, and though the attendance was not large, the topics introduced by the President, and his supporters, Dr. Durrant, Dr. Ranking, &c., &c., professional and private, were very instructive, and the day passed throughout with those feelings of mutual cordiality which it is the great object of these branch meetings to promote.

JOHN KIRKMAN, Hon. Sec.

PROTEST OF THE ASSOCIATED EXTRA-URBEM LICENTIATES OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AGAINST THE PROPOSED NEW CHARTER.

To J. A. Paris, M.D., &c., &c., President of the Royal College of Physicians of London.

SIR,—The Committee of the Associated *Extra-Urbem* Licentiates of the College have had the Draft of the Proposed New Charter under their consideration, and have desired me to communicate with you respecting it.

The Committee observe, that it is proposed to incorporate the *Extra-Urbem* Licentiates in a new College, to be called the Royal College of Physicians of England, on the following conditions:—

1. That they present testimonials of character satisfactory to the Censors.

2. That they pay to the funds of the new College the sum of fifteen pounds, fifteen shillings.

3. That they contribute to the National Exchequer by the payment of a stamp duty.

As to the *first* condition, they desire me to say that the *Extra-Urbem* Licentiates already hold letters-testimonial as valid in law as the Charter of the College itself, and they are of opinion that the rights attached to these letters-testimonial ought not to be placed at the arbitrary discretion of the "Censors." The Committee also wish me to call your attention to the fact, that they were only granted upon the production of testimonials of character satisfactory to an examining board, constituted of yourself, (or your predecessor in the chair,) and three senior Fellows of the College, and are duly signed by the Examiners according to the statute; and that, consequently, any further testimonials are quite unnecessary, unless it is proposed to extend the inquiry to the Fellows and *Intra-Urbem* Licentiates.

As to the *second* condition, the Committee desire me to say, that they are willing to contribute a proportion of such sums of money as may be found necessary to place the proposed new College in a sound and honourable position; but they would also urge, that it is manifestly unjust to demand the same payment on admission from the physician, legally qualified by compliance with the statutes of the realm, as is demanded from the physician not so qualified.

As to the *third* condition, the Committee cannot comprehend why the incorporation, for the public good, of a body of professional men, already heavily taxed, should be made the occasion for inflicting further taxation. In addition also to the fact, that the majority have already paid a stamp duty on their diploma, the Committee would state, the University-of-Oxford-Commission recommends the abolition of the stamp duties on matriculation, and on certificates for degrees, thus affording an example worthy the consideration of the College.

The Committee would state, that they deeply regret there are persons practising as physicians whose conduct renders them unfit to be incorporated with the general body; but as such are to be found in every class, they think it both impolitic and unjust to single out one class, or more, for special inquiry. Further, however

unfit any one may be, they think no one should be deprived of his position and privilege by an irresponsible Board, however designated, nor without an impartial inquiry, according to legal forms, and under the guidance of a written code of medical laws, to be appended to, or embodied in, the Charter.

The Committee observe that it is now ten years since the organization of the Physicians of England was first undertaken by the College, and that this is the *third* Draft Charter which it has edited. It is obvious that this will never pass into law, and that another attempt will have to be made. On every account the Committee regret these repeated failures, being convinced that they are injurious to all parties; and they cannot but urge most earnestly upon the College the propriety and wisdom of ascertaining by full and free communication, the feelings and wishes of the Physicians of England, resident both in London and the provinces—not only as to the terms of incorporation, but also as to the future government of the College; so that they may be all united into one body, jealous of the honour of the profession, able to defend and maintain its dignity, zealous for the advancement of medical science, and anxious for its applications to all those great improvements in social economy which the age so earnestly demands.

I have the honour to be, Sir,

Your most faithful Servant,

THOMAS LAYCOCK,

Hon. Sec. to the Associated Extra-Urbem Licentiates.

York, June 10, 1852.

THE MEMORIAL OF THE EXTRA-URBEM LICENTIATES, AND THE NEW CHARTER OF THE COLLEGE OF PHYSICIANS.

The following letter has been received by Dr. Laycock from Dr. Hawkins, in acknowledgment of the Memorial of the Associated Extra-Urbem Licentiates:—

"College of Physicians, London, June 22, 1852.

"SIR,—I beg to inform you that your Memorial, addressed to the President of the Royal College of Physicians, has been laid before a Committee of the College, and has been received by them with the attention due to it. I am directed, however, to state that no further measures can be taken at present towards obtaining a new Charter for the College, on account of the impossibility of procuring an Act from the present Parliament. And I am to assure you that, before any settlement is come to between the College and the Government, the arguments contained in your Memorial shall receive the fullest consideration.

"I am, Sir, your obedient Servant,

"FRANCIS HAWKINS, M.D., Registrar.

"To Dr. Laycock, &c., &c., &c."

Correspondence.

DR. COWAN'S PROPOSED ALTERATION OF THE "JOURNAL."

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—As Dr. Cowan is about to propose some alteration in the publications of the Association, the present is the fit time for the members to state their opinions; and as one who for some years has rejoiced in the well-being and well-doing of the Society, I venture to make a few remarks, which I shall be glad to have inserted in the next number of the *Journal*, that they may be considered before the Oxford meeting.

An objection of some importance in these times, is made by those who view it as a commercial question—that for the guinea subscription they do not receive twenty-one shillings' value. They say that they only have a *Journal* twice a month, and now and then some cases and essays sewn together. Now, certainly this ought not to cost a guinea. If we look at the *Medical Times and Gazette*—a good weekly paper—we find that the publisher supplies it at 25s. a year. If it were to come out fortnightly it would be 12s. 6d. a year. Now the cost of the *Journal* is 19s. 4d. a year, instead of 12s. 6d. But it ought to be much less than the price of the *Medical Times*, for there is no person to be paid except the editor and the printer. There is not, as is the case with the London Medical Journals, a weekly amount payable to home and foreign correspondents, no sub-editors, no occasional contributors, no publisher, and lastly, no proprietor to receive remuneration and profits out of the returns. Surely then a weekly journal could be and ought to be issued at a less expense than the fortnightly one now is. The "Transactions," too, have much fallen off. Instead of being published in a bound annual volume of 500 or 600 pages, there are now irregular deliveries of a "part" in a paper cover. As regards material, there have been and now frequently are, highly important and interesting communications, both in the *Journal* and "Transactions." But I would suggest that their pages, being for the perusal of practitioners rather than of students, are not adapted for the publication of courses of lectures. As you, Sir, remark in your last article, it is to the members that the Editor looks for papers and cases; and they ought to be supplied in abundance sufficient for you to have an ample choice. All will agree that the larger the Association, the more efficient it will be; it therefore behoves the Council to use every effort to induce all regular practitioners to become members, and I suggest, as a means of increasing our numbers:—1st. That the *Journal* shall be published weekly, improved by infusing more spirit into the leading articles, and giving more general intelligence, so as to preclude the necessity (which at present exists) for every member to take in also a London Medical Journal to learn what is passing in the medical world. 2nd. To improve and increase the "Transactions" by adding to their quality and quantity; or, by omitting them altogether, to lessen the subscription from 21s. to 15s., or to continue the

present amount and reserve 5s. as each member's subscription towards a Provident Medical Fund.

Such, Sir, are the remarks which, in all good feeling and friendship, I offer to the members of the Association; and I am ready to acquiesce in any improvement which may be made in either or any of the Society's publications.

I am, Sir, your obedient servant,

W.

June 26, 1852.

MEDICAL ETHICS.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—The above subject has long and seriously occupied the professional mind of this country, and is assuming a fresh importance week by week, both among the periodicals and various Societies throughout England, on account of the evils which do arise from the want of corporate government. Under these circumstances would you permit me to suggest, that it would be well if some of the older and more influential of our body would turn their attention immediately to the subject, and propose some feasible remedy for such evils at the forthcoming annual meeting at Oxford. I am aware that a proposition for a Medical Reform Bill will then be submitted by the Council to the Association, which will deal with the heavier grievances under which we all labour; but there are many minor ones which that Bill would never reach, and it is to these I would now draw attention.

It is clear to everybody that the profession is always increasing in members, and that there is no guarantee that they shall all be honourable men, and kept honourable, but that in the heat of the race each one is left to his own discretion, to benefit himself, or damage his neighbour, by whatsoever means he thinks fit. It may be true that persons of downright bad character are comparatively rare amongst us, and that we exhibit as a whole a very noble combination of talent, learning, honour, benevolence, and truth; but still the above state of things ought not to exist, especially when we know that one bad man is enough to sow discord amongst many good ones, and that, as a matter of fact, even the most eminent and most amiable amongst us are apt to fall out, and to remain alienated from each other, because their sense of pride—or dignity, if you will, will not permit them to make the first advances to reconciliation, and also because there is no proper medium through which such desirable reconciliation may be effected.

Now, what I would propose, and what some gentlemen of greater age and influence might readily carry out, or at least lay the foundation of, at the meeting of the Association, is a scheme by which the Council might appoint boards of umpires within each convenient district to whom all differences amongst members might be submitted for arbitration. Although such institutions could affect the members of the Association alone in a direct manner, yet, indirectly, they would exercise a very wholesome influence on the entire profession, and be an excellent temporary substitute for that more

universal corporate government which must, sooner or later, prevail amongst us.

There are some offences that should, and, I am informed will soon be positively uncompromisable and penal; such as, firstly, the semi or extra-professional offence of adventuring to practise without any legal diploma at all; secondly, the fraudulent assumption of additional titles and honors by certain members of the profession, obviously with the view of elevating their own importance as compared with others, and who are evidently only one remove from the open and undisguised quack; thirdly, those who practise the bill-sticking and advertising system. The first of these, never belonging to us, will simply be prevented from attempting to make it appear as if they were medical men; and the two latter classes can only be visited with expulsion under any sound regulations that may be framed for professional government.

Besides such gross derelictions as the above, however, there are sundry lesser deviations from strict rectitude, leading to differences which such boards of umpires might easily heal. Many differences often do arise, not from any real or actual cause, but from misreports of the truth, or from the intermeddling of "good-natured friends;" which differences are prevented from being arranged by that sense of personal pride or dignity above adverted to. Many talented, amiable, and high-minded men are thus kept permanently aloof from each other, who might otherwise easily come to explanations which would terminate in a generous and brotherly friendship. There are also many underworkings, whether of a scientific or a monetary character, yet all springing from rivalry or jealousy in some shape or other, which have for their object the depreciation of other men's talents and virtues, and the depriving them of their practice by innumerable little tricks, all of which it would be impossible to mention, but which each one can understand according to his own experience. These annoyances, which every man, I believe, has felt at one time or other, along with the evils of ruinous contractings and competition, especially in the parochial and club systems, are really deserving of grave attention. The very actors themselves in these cases condemn the nuisance, but say they cannot help it; they must do as others do, in self-defence, because they must live; and all of them yearn with one mind for some authoritative interference. Let the Provincial Medical and Surgical Association take the lead, and we may then have some hope.

I remain, &c.,

June 19, 1852.

VOX.

LANCASHIRE AND CHESHIRE BRANCH MEETING.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—As I shall not be able to forward you a report of the proceedings of the late anniversary of the Lancashire and Cheshire Branch, in time for insertion in the forthcoming number of the *Journal*, I hope you will excuse me intruding this brief communication upon you, and beg the favour of its insertion in *Wednesday's Journal*.

From the first establishment of our Branch, the members have paid their own local expenses; the Council authorising the Secretary to call for a subscription whenever he found it requisite. The uncertainty of this mode of proceeding, in the members not knowing how much they might be in arrear, if they did not attend the annual meetings, induced the Council in 1849, to alter the rules and render it obligatory for each member to pay 2s. 6d. annually, towards defraying the incidental necessary expenses; the consequence of which has been, that although the Association at that time was in debt to the Secretary, we were enabled, out of our surplus, on Wednesday last, to vote a donation of £5 to the Benevolent Fund, which I have handed over to Mr. Newnham.

As the Association will be holding its meeting at Oxford, before the day of your issuing another publication, I shall be obliged by your inserting this, in the hope that it may draw the attention of my brother Associates to so gratifying a result, and that they may induce their different branches to follow our example.

We none of us "*grudge*" the 2s. 6d. If we were to call upon the Association for a seventh part of our subscriptions, we should saddle the Parent Association with an annual payment of nearly £18, as we number about 120 members.

I am, Sir, your obedient Servant,

JOHN HATTON,

July 3, 1852

Hon. Sec.

Medical Intelligence.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 18th of June:—Alfred James Barker, Paramatta, Australia; George Frederick Dansey, Blandford, Dorset; Daniel Gwynne, Brighton; Frederick Lewis Leonard, Royal Navy; Charles Lewis, Killarney; Robert Marsland, Manchester; Charles Palmer, Kirton-in-Lindsey, Lincolnshire; Samuel S. Skipton, London; Charles Taurrette, Mauritius; Thomas Wigglesworth, Coleford, Gloucestershire.

The following gentlemen were also admitted on the 25th of June:—Robert Joseph Biggs, Kingswood Hill, Gloucestershire; Joseph Cockshott, Dublin; William Collingwood, Camberwell; Nathaniel James Grant, Thayer Street, Manchester Square; Thomas Edward Halls, Horselydown; William Little, Corsham, Wiltshire; John Mageniss, Beltrubet, county Cavan; Eugene O'Neile, Cork; Charles Frederick Perceval, Kilmore Hill, Waterford; Matthew Bass Smith, Louth, Lincolnshire; Alderman Thomas Houghton Waters, Minley Manor-house, Hants; Thomas Westropp, Ardcanney, co. Limerick.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 17th of June:—Arthur Dix, Beech Street, Barbican; George Puckle, Camberwell; John Reynolds Salter, Exeter; Peter Vincent Timothy, Redcross Street, Barbican.

Gentlemen admitted members on the 24th of June:—James Atkinson, Malton, Yorkshire; George Dransfield Brown, Croydon; Merrick Lloyd Burrows, Dunkirk, Devides; Maurice Davis, Thame, Oxon; George D. Freeman, Bath; Thomas Artindale Handsley, Alford,

Lancashire; Henry Jardine, London; Richard Balfour Reid, Liverpool; Anthony Ridley, Sunderland; Robt. Todd, Edinburgh.

THE ROYAL SOCIETY.

In the list of newly-elected Fellows of the Royal Society, we are happy to perceive the name of John Higginbottom, Esq., surgeon, of Nottingham. His contributions to medical science, as well as those in connection with a branch of natural history not generally understood, have well entitled him to that distinguished honour which the Council of the Royal Society has conferred upon him.

OBITUARY.

June 28th, at Fitzwilliam Street, Huddersfield, aged 41 years, Dr. John Taylor, Physician to the Huddersfield Infirmary, Fellow of the Royal College of Physicians, and late Professor of Clinical Medicine, University College, London.

Lately, on his passage to the Cape of Good Hope, Dr. Ingram, surgeon of the *Gloriana*, from disease of the heart.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

BATH AND BRISTOL BRANCH.

The annual meeting of the Bath and Bristol Branch will be held on Thursday, July 15, in the Board Room of the Bath General Hospital, Union Street, at 2 p.m., when Dr. Symonds will resign the chair to George Norman, Esq., President-Elect.

After the Report has been read and the ordinary business transacted, John Grant Wilson, Esq., will propose that the following resolution be adopted by this Branch, and recommended for the consideration of the Parent Association at its next Anniversary:—

"That the Members of this Branch of the Provincial Medical and Surgical Association, feeling most strongly the gross injustice of being expected to furnish gratuitously a private report of the healthful condition or otherwise of their patients to any Life-Insurance Company that may choose to apply for it, and being fully convinced that the information so supplied is for the security and advantage of the insurer rather than the individual insuring, do hereby express their determination not to reply to any questions submitted to them by an Insurance office that does not transmit with the questions a suitable fee."

Members having any communications for the meeting are requested to give notice of them to the Secretaries.

The Dinner will be at the Castle Hotel, at half-past five o'clock. Dinner tickets, including dinner, wines, coffee, and waiters, 14s. each.

J. S. BARTRUM,

Bath, 41, Gay Street.

J. COLTHURST,

Clifton, 11, The Mall.

Hon Secretaries.

TO CORRESPONDENTS.

Communications have been received from Mr. Paterson, Dr. Kirkman, Dr. Cotton, Dr. Bayes, Oculus Apertus, Dr. Tilt, Dr. Sandwith, Mr. Cowley, Mr. Hawtayne. It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

ON

A VARIETY OF LATENT PNEUMONIA.

By C. M. DURRANT, M.D.,

PHYSICIAN TO THE EAST SUFFOLK AND IPSWICH HOSPITAL.

Read before the Meeting of the Suffolk Branch, held June 25th, 1892.

MANY cases of a form of pneumonia having presented themselves to my notice, both in hospital and private practice, during the past two years, in which the general symptoms in reference, equally to the patient as to the observer, have been so slight, (the disease at the same time being extensive in its pathological results,) that I have deemed it not an unfit subject to bring before the present meeting.

In the last volume of the "Transactions" of our Association, there is a paper by Mr. Caleb Williams upon "The Present Type and Character of Disease." This paper is one of great value, as setting before the profession in the clearest manner the altered type of disease generally in the present day, as combined with the character which obtained to the majority of disorders some twenty-five years ago.

I have ventured upon this digression—first, because it gives me an opportunity of strongly recommending the perusal of Mr. Williams's paper; and, secondly, because in the very latent form of pneumonia to which I am about to direct your attention, the existence of the present constitutional character of disease exerts, if not a primary, a very strongly modifying influence.

The symptoms as occurring in private practice may perhaps be best detailed by the brief recital of a case which presented itself to my notice a few weeks ago:—

The patient, a middle-aged man, and a stranger to me, commenced the description of his sensations by saying,—“Doctor, I am not well, and I cannot tell what ails me. I am not aware that I have taken cold; I have no cough, and no pain, but still I feel a sensation of weight in my side that reminds me continually that I have a side. These feelings of *malaise* (he continued) have been upon me for nearly three weeks.” Upon inquiring if his breathing were affected, he replied:—“Now you direct my attention to the circumstance, it certainly has been somewhat short at times, but I have not thought much of it.” This gentleman's countenance was dull, and his cheeks reddish; the eyes heavy, and the conjunctivæ slightly yellow; tongue not much coated, and moist; pulse 80, of moderate strength; breathing at the time of examination not accelerated; bowels sluggish; urine occasionally depositing a sediment. His appetite, he said, was “too good,” and he slept well, and the temperature of the skin was but slightly above the natural standard. Upon baring the chest for the purpose of making a stethoscopic examination, I found that the ribs upon the right side acted less freely than on the left, and over a very large portion, nearly two-thirds of that lung, the respiratory murmur (unaffected by position,) was almost inaudible, while the sound elicited by percussion was characteristically dull to a corresponding extent.

This case required a steady perseverance in the treatment presently to be advised, before a return of the feelings of health could be obtained, and which occurred simultaneously with the restoration of the natural breathing.

I have endeavoured thus to give, in the somewhat graphic language of the patient himself, a description of the very few symptoms, and these the most prominent, which presented themselves in this obscure form of pneumonia, and which, whether occurring in what was formerly more particularly designated the plethoric constitution, or its reverse; or whether, attacking the well-fed among the higher classes, or the labourer and artisan, still the symptoms will be found to bear no proportion to the extent of lesion to which the disease gives rise. The affection under consideration is essentially characterized by negative results,—viz., an absence of those symptoms to which we generally refer as evidencing a serious interference with the healthy function of respiration. For example:—We have seldom rigor complained of at the onset; the countenance, although dull and heavy, is not anxious; debility is almost universally complained of as a leading symptom; there is in general no severe pain; the cough, if there be any, is not distressing, and the amount of expectoration either inappreciable, or if more abundant, it is untinted mucus; the breathing may be short, but not sufficiently hurried to attract much attention; the *alæ nasi* are quiescent; the skin is in general moist, and free from that pungent heat so characteristic of the more acute form of attack; the pulse is either natural in frequency, or but slightly accelerated, rarely above 90; the urine is for the most part free from deposit, and in sufficient quantity. The physical signs, however, are well marked, and will, if carefully sought for, unfailingly indicate the true nature of what, without this aid, must often be doubtful and embarrassing.

The tendency of this form of pneumonia, so far as my own observations have led me to observe, has been towards recovery. Tedious,—very tedious, both to patient and practitioner, it will sometimes prove; but I have not found, provided that the subject of the attack be not already labouring under phthisis, that it either predisposes to, or merges into that malady.

The cause of this disease is not, I believe, so much attributable to cold as to a disordered condition of the primary and secondary assimilative processes, inducing as a consequence a morbid state of the blood itself; this, by depressing nervous power, subsequently causes in its transit through the lung, irritation and congestion, followed by adynamic inflammation, with exudation. The disease may pass through its different stages with so little disturbance to the pulmonary organs, that, as in the case above referred to, the patient will attribute his disordered feelings to any but the right cause.

Since writing these notes I have seen another instance in which the patient, unconscious of the existence of any serious lung affection whatever, (but in whom, nevertheless, more than one half of the left lung was in a consolidated state,) attributed all his discomfort to an affection of the stomach. The treatment that I have

hitherto found to be most beneficial has been chiefly confined to counter-irritation, the guarded introduction of mercury, (with a view to the correction of morbid secretions, and carried to the extreme of very slightly affecting the gums,) the iodide of potassium, and cod-liver oil.

Venesection is in no case called for, as a dangerous degree of depression may be expected to follow the use of depletory measures. Cupping, or even leeches, will seldom be needed, unless an unusual degree of pain be complained of, which is quite contrary to what ordinarily obtains. Blisters will be found to be of signal service, and these must be repeated again and again, not kept open, but permitted to heal; and their renewal, as well as any change of locality, must be influenced by the result of carefully-repeated stethoscopic investigation. Should any indication of an indurated portion of lung remain after the application of from three to five blisters, at weekly intervals, a strong solution of iodine (one drachm of iodine, and half a drachm of iodide of potassium, to one ounce of rectified spirit,) painted, if it can be borne, once daily over the affected spot, will be found at this stage very useful. If the secretions be much deranged, small doses of the hydragryum cum cretâ should be given, slightly, and only slightly, to affect the gums; or what will then be found to be a still better form is the bichloride, in doses of one-sixteenth of a grain, night and morning. Iodide of potassium, with alkaline salines, will be called for, to be followed by cod-liver oil, in doses from a teaspoonful to a tablespoonful thrice a day. This latter remedy has given me much satisfaction in the treatment of pulmonary indurations of an adynamic character; and it has exerted a very marked influence in promoting the absorption of morbid exudation. This, I presume, it can alone effect by improving the condition of the general health.

ON THE

TREATMENT OF ERYSIPELAS BY THE MURIATED TINCTURE OF IRON.

By W. H. RANKING, M.D., CANTAB.,

PHYSICIAN TO THE NORFOLK AND NORWICH HOSPITAL.

Read before the Meeting of the Suffolk Branch, June 25th, 1882.

It has always been my opinion that the communications most suitable to the brief reunions which take place at these anniversaries of the several Branches of the Provincial Medical and Surgical Association, are those which are able to convey practical information in few words; for this reason I have selected for your attention a case which has recently come under my notice, and in which a method of treatment not commonly followed has proved eminently successful. I allude to the treatment of erysipelas by the muriated tincture of iron. The case is as follows:—

Charlotte Andrews, aged 23, a fat strumous girl, was

admitted into the Norfolk and Norwich Hospital under my care, in April, for engorged and suppurating cervical glands, which were treated by generous diet, cod-liver oil, free lancing, and subsequent dressing with the iodide of lead ointment, an application which I may state in passing, appears to me to be more suitable to scrofulous ulcers than any other with which I am acquainted. Under this treatment her progress was all that could be desired, until the 26th of May, when my attention was called to an erysipelatous redness over the right breast. This quickly extended, and in spite of the assiduous endeavour on the part of our intelligent house-surgeon, to limit its boundaries by the nitrate of silver, it soon invaded the head and face, inducing those serious symptoms which are observed in these cases. As soon as the disease fully declared itself, no time was lost, as is my invariable custom, in sustaining the powers of the patient by wine, beef-tea, and ammonia, the local application being flour.

On the 28th, the disease had continued to extend, and as the patient was losing strength the ammonia was replaced by quinine.

On the 29th, the report is that the erysipelas had occupied the entire head and face, and was creeping down the back. The patient was delirious, with dry tongue and feeble pulse of 130.

On the 30th she was still worse, the tongue was more dry and dark, and diarrhoea was added to the other unfavourable symptoms. Wine was given in increasing quantities, so that she took more than a bottle in the twenty-four hours.

June 1st.—She was still more depressed; pulse 140, fluttering; the face livid, and she appeared to be fast sinking. At this time I determined to administer the muriated tincture of iron, as recommended by Mr. Bell, of Edinburgh, and did so, as will be seen, with the best results. The dose was forty minims in water, every three hours. In the evening, after three doses, the pulse was still 140, but had more resistance to the finger, and she was left for the night, with orders to continue the medicine and wine.

On the 2nd there was a most marvellous change for the better. The tongue, which the day before was dry and dark, was now moist and cleaner, the pulse had sunk to 120, and the patient was able to raise herself in bed. The face was desquamating and her only complaint was urgent thirst, which was gratified with water *ad libitum*.

3rd.—I continued the iron in doses of thirty-six drops. The improvement was still more manifest; the face had become more natural in appearance, and she was pronounced out of danger. From this time her recovery was uninterrupted.

Knowing how difficult it is to establish a medical fact, I am prepared to find that some of my hearers may dispute the agency of the iron in this girl's recovery. On this point I would only say, that prior to her taking that medicine she lost ground hourly, in spite of the freest exhibition of wine, ammonia, and quinine; and that after three or four doses a perceptible advantage had been gained, which advantage was rendered indisputable on the

next day by the improved condition of the pulse and tongue, and the rapid subsidence of the cutaneous engorgement.

I take no credit to myself for this mode of treating erysipelas, but most willingly record my obligation to Mr. Bell, of Edinburgh, who published a paper on the subject in the *Monthly Journal of Medical Sciences* for June, 1851. That gentleman's testimony as to the value of this treatment is most strong; he says that in every instance in his practice it has been successful. His brother, Dr. Charles Bell, is equally impressed in its favour; and he states that it not only removes the disease in a short time, but also renders the patient less susceptible of returns of the disease. In pursuing the chalybeate treatment of erysipelas, Mr. Bell regards it as important to bring the system rapidly under its influence, and acting on this conviction, I gave in the case above related even larger doses than Mr. Bell had sanctioned.

Although the case I have related was an instance of idiopathic erysipelas, the treatment is said to be equally beneficial in the traumatic form, and in infantile erysipelas. Of the latter, Mr. Bell details some remarkably interesting cases.

CASE OF PUERPERAL CONVULSIONS.

By ROBERT MARTIN, Esq., HOLBROOK.

Read before the Meeting of the Suffolk Branch, held June 25th, 1852.

MARY COUSINS, was admitted into Farningham Union House, at the age of seven weeks, consequent on her mother suffering from puerperal mania. The mother remains to this day a confirmed lunatic in Melton Asylum.

Mary Cousins, the infant, was reared in the Union House, and the nurse who had charge of her states that she was frequently the subject of severe sick headache, which at times confined her to her bed for days together. She was early placed out in service, and but little is known of her, till her readmission to the Union House, in an advanced state of pregnancy. Since her readmission she is said to have suffered much from headache, but never reported herself nor authorised others to report her to the medical officer.

Mary Cousins, aged 21 years, primipara, visited by Mr. Jarman, at 1 A.M., May 3rd, 1852. Was in the first stage of labour, with slight pains, restless, irritable, and constantly walking about the room; pains regular at short intervals, producing little effect on the os uteri; was suddenly seized with convulsions, on the subsidence of which she was conscious, and complained of pain in the head; skin temperate; pulse weak at the wrists, but strong at the carotids; bladder and bowels had been freely relieved.

At half-past three A.M., I saw her, she had just recovered from a severe fit; was conscious, but rather wandering; complained of headache; pupils dilated; face but little flushed; pulse 100; not full, nor sharp,

excepting in the carotids; pains regular at intervals of four or five minutes; os uteri dilated to nearly the size of a crown piece, thin, but rigid; membranes entire; no presentation of the child discoverable; bled to twenty ounces from the arm, with decided impression on the system; several pains succeeded without fit; the head, however, much complained of; suddenly seized with a severe fit, grinding of teeth, torticollis, opisthotonos; the tongue was protected from injury by a gag; at the termination of this fit, the head of the fœtus was advanced, having descended to the hollow of the sacrum; during the fit a considerable but indefinite quantity of blood was lost from the arm into the bed, the bandage having slipped; I applied the forceps, and delivery was speedily and easily effected at half-past five, A.M.

The birth of a living child was instantly succeeded by a violent fit, with, from this moment, no recurrence of consciousness. The placenta was naturally expelled a few minutes after the fit, with more than usual loss. The uterus, however, quickly, by means of friction over its fundus and pressure, contracted firmly. Coma like a heavy sleep, supervened, without stertor or laryngismus; pulse quick and feeble. The hair was removed from the head, and cold applications employed; ten grains of calomel were placed on the back of the tongue, and the inside of the cheeks smeared with croton oil, at intervals of one hour, four times, without effect on the bowels. Mustard poultices were applied to the feet, and the region of the cervical vertebræ covered by a flannel wrung from hot water, and soaked in turpentine. Coma increased in intensity, laryngismus, and forcible expiration. At ten o'clock a few ounces more blood were drawn from the arm; but it was clear the system would not bear much, and death closed the scene about twelve o'clock.

Sec tio-cadaveris.—Pericranium healthy; calvarium natural in density and weight, strongly adherent to the dura mater at the vertex only; dura mater natural in general appearance, but tensely stretched over the brain, especially at the posterior lobes of the cerebrum, and presenting an elevated knotty induration, of nearly an inch and a half in length, over the superior longitudinal sinus, at the posterior termination of the sagittal suture, where it had been adherent to the calvarium, and where the sinus receives the parietal veins. An incision made below this tumefaction into the superior longitudinal sinus, would not permit the fine point of my blow-pipe to be passed forwards through its track, although it was permeable by air. The induration consisted of enlarged Pacchionian glands, which springing from the pia mater, had thrust the floor and roof of the superior longitudinal sinus against the calvarium, and thus obstructing circulation through the sinus; anterior to this obstruction the sinus was much enlarged, and would readily admit my index finger; it contained several clots of blood; on cutting round the dura mater the lobes of the brain expanded with an audible noise; the vessels of the pia mater were much distended with blood; substance of the brain healthy; horizontal sections discovered many spots of effused

coagula, especially in the right posterior lobe; the ventricles contained no fluid; plexus choroides more pale, and less vascular than usual; base of the skull contained three ounces and a half of bloody serum, compressing the medulla oblongata at the foramen magnum.

Now, Mr. President, such a case as the one narrated, viewed irrespectively of its previous history, which can sometimes be only imperfectly, and at other times not at all arrived at, presents a grave question to the practitioners, viz.,—Do the epileptic convulsions depend solely on reflex action of the spinal nerves, or is that source of irritation complicated with intra-cranial pathology? On the first supposition, chloroform to allay spasm, with the speediest practicable delivery by turning or forceps, would be indicated; but on the second, such a case for instance as that of Mary Cousins, I fear chloroform might increase cerebral congestion, while operative measures, without its anesthetic agency, by augmenting spinal irritation, might hasten the fatal coma, and thus rendering necessary the adoption of an ulterior proceeding. An accurate diagnosis is, therefore, of the utmost importance.

I have witnessed, I apprehend, several cases of both kinds, cerebriac and excerebriac, or at least I have inferred so from the results, referring to reflex action those which have recovered, leaving no trace of intra-cranial disturbance, and to cerebriac origin those which have died in which my classification has been guided by *post-mortem* inspection, but which during life presented no appreciable difference in symptoms.

Should this subject have occupied the attention of yourself, Mr. President, or of any of the members of this Association, I shall be glad to learn from you a means of clear diagnosis between puerperal epileptic convulsions dependent on reflex action of the spinal nerves simply, and those which, as in the case I have narrated, are complicated with intra-cranial pathology.

In order to obtain the opinion of that distinguished physiologist, Dr. Marshall Hall, on this subject, I addressed a letter to him, making the direct inquiry of diagnosis, and repressing the previous history of the case I sent its detail. I have now the pleasure to read you his courteous reply, from which I infer, that under any circumstances of the kind, he would not permit his patient to die without the performance of tracheotomy, and it is possible that in the case of Mary Cousins, had it been resorted to before the lesion of vessels occurred, life *might* have been preserved.

CASE OF HAY FEVER.

By WILLIAM P. KIRKMAN, Esq., MELTON.

Read before the Suffolk Branch Meeting, June 25, 1952.

BEING but too personally concerned in the following case, I am induced to bring before your notice this afternoon some brief notes of a very troublesome affec-

tion, which has as yet continued to bid defiance to the skill of the most eminent and learned in our profession; and when I tell you that I am annually afflicted with this "thorn in the flesh," and have been for the last seven years, I doubt not but that you will be kind enough to give my case your favourable consideration; that I, like the bee which gathers honey from every flower, and lays it up for the ensuing year, may, from whatever suggestions you shall kindly afford, gather such an amount of therapeutical information, as will give me the chance of wielding an effectual weapon, with a view to the downfall of my annual visitant.

The disease presents many peculiarities, but little is known of its pathology; and with respect to its cure we are in total ignorance of any remedial agent. There is one circumstance worth remarking before I proceed, which is, that very probably you will, before I have terminated my notes, (brief as they shall be,) have an ocular demonstration of some of the more urgent symptoms of a truly distressing affection, commonly known under the name of catarrhus aestivus, or hay fever. Seeking then, gentlemen, your valuable aid, I proceed to give as concisely and plainly as possible a short detail of my symptoms as they annually attack me.

Every year, at about the latter end of the month of May, a slight irritability and sensation of soreness at the inner canthi of both eyes is experienced. This continues on and off, unaccompanied by any other marked symptoms, perhaps for three or four days (no symptoms of febrile irritation whatever); to these are shortly added slight lachrymation, which subsequently becomes more profuse, and continues daily, with irritation at the inner canthi, to increase; the nostrils, one or both, become obstructed, and this is soon followed by itching, sensation of pricking and soreness in the same region; the Schneiderian membrane now begins to secrete a quantity of thin watery fluid, calling for the almost incessant use of the pocket handkerchief; in fact, by the commencement of the month of June, there are all the appearances of what is vulgarly called, "a running cold;" these daily, but gradually, increase, and as gradually become accompanied by other concomitants, until about the end of June or the commencement of July, when the affection is at its height and presents the following distressing symptoms:—There is intense itching and irritability of the conjunctivæ, especially towards the inner canthi, as well as of the Schneiderian membrane; profuse lachrymation, and when the attacks are severe, considerable intolerance of light; violent and continued sneezing, sometimes twenty or thirty times without ceasing; the defluxion from the nostrils is immense; there is coryza and gravedo with dyspnoea, which is frequently accompanied by wheezing during inspiration; the breathing being carried on by the mouth alone, as both nostrils are blocked up by the amount of secretion given out by their lining membrane. If these continue long, the eyes become bloodshot; there is headache, more or less severe; the pulse becomes small and weak; the tongue white and coated; shooting and darting pains about the back part of the head; lassitude and great debility. One might

be inclined to doubt whether these evidences of the disease were not somewhat exaggerated, but it is not so. I have detailed to you as correctly as I can everything relative to the symptoms and order of their occurrence as they attack myself individually, without any reference whatever to any medical author. I am generally free from the affection about the latter end of July, and I think I may say by the end of the first week in August, no traces of its existence remain manifest. It is equally severe in London as in the country. I am always worse during the day, and if in the forenoon the sun is shining bright, I hardly dare venture out of doors, the intolerance of light being almost unbearable. The relief which is experienced for a few hours after a heavy shower of rain, can hardly be imagined, and the symptoms are always less distressing in wet weather. Again, it nearly always leaves me for a short time, sometimes a day or two after a thunder-storm; and to this partly, is my presence before you now to be attributed, for you will remember that yesterday we had a considerable amount of thunder and lightning; this circumstance, moreover, would tend to favour the idea entertained by some, both with respect to this, as well as to influenza, that the cause is to be attributed to some change in the electrical condition of the atmosphere—whether to an accumulation or deficiency of the electric fluid I am not enabled to state. *Ipecacuanha*, it may be remarked, has no further effect upon me than the application of any other pulverulent matter would be supposed to have. On several occasions a pinch has been taken, the same as one would take a pinch of snuff, without producing any effect. I need hardly state that this was done merely by way of experiment. A sudden draught will bring on an attack immediately, which will continue for an hour or two, or even longer.

One word may, perhaps, be desirable, relative to that from which it has derived its name, I mean hay, which brings on an attack, especially if it be new, almost instantaneously; and what is very remarkable and curious is, that I can always tell when any hay is approaching me, even if I do not see it. On one occasion, when walking in London with my friend Dr. Robert Growse, of Bildestone, I suddenly stopped, remarking that I would take any even wager that there was some hay close by. Before the doctor could hardly reply, a cart full of hay passed the end of the street down which we were proceeding. I could, were it necessary, relate to you many other similar occurrences; the one, however, which I have mentioned, is sufficient to verify my statement, and time will not allow of more. What then, gentlemen, is the cause of this periodical, but unwelcome visitor? I should feel inclined to differ somewhat from the opinion of Dr. Gordon, who supposes that it is produced by pollen from *one particular plant*, viz., the *anthoxanthum odoratum*, or sweet-scented vernal grass; and for this reason, because I am always attacked at least three weeks before the *anthoxanthum* is in blossom. If I may be allowed to offer my opinion, I consider it to be attributable to an idiosyncrasy of constitution, whereby the whole of the gastro-pulmonary mucous membrane is

rendered susceptible of irritation, that irritation being produced by the pollen from a certain class of plants which blossom at that time of the year when the affection is prevalent. I refer to the whole family of the *graminaceæ*, rather than to any individual plant.

And now, gentlemen, one word with respect to the treatment. It would, indeed, be preposterous in me, were I to make remarks on all the so-called remedies which have been recommended by various writers; suffice it to say, that I have tried very many of them, and all without effect; never have I found anything which afforded me the slightest permanent relief. Hot water fomentations, drinking hot water, cold water draughts, effervescing mixtures, pressure on the bridge of the nose, have all in their turns carried off a paroxysmal attack of sneezing; but the good fortune of finding any thing capable of allaying the almost intolerable itching of the eyes and nose, has never fallen to my lot. Dr. Owen Rees, Assistant-physician to Guy's Hospital, recommended large doses of dilute sulphuric acid. I commenced with twenty minims three times a day, which, according to the direction of the Doctor, I gradually increased, until I arrived at a dose of one drachm three times a day. This had no other effect more than occasionally favouring me with a violent pain in the bowels, which compelled me to desist. Dr. Golding Bird and Dr. Gull, in consultation, recommended the disulphate of quinine with iron; this I continued to take for some considerable time, commencing at the ordinary dose, and increasing it gradually, which, however, proved equally ineffectual. *Strychnia*, recommended by Dr. Addison, in doses varying from the one-twentieth to one-twelfth of a grain, *ter in die*, was tried, but proved useless. Arsenic, sulphate of zinc, tincture of the *lobelia inflata*, snuff, laudanum, salines of all kinds, iodine, and a host of others which now escape my memory, have all had pretty fair trials, which, as remedial agents in hay-fever, are all on a par. Such, then, gentlemen, is the hay-fever in my case. If you can kindly suggest any thing, I shall be only too glad to give it a fair trial, and report to you the effect at your next meeting. Some apology may be necessary for the little interest which this case is likely to afford you, nor indeed should I have considered it worthy of your attention, had not the subject been introduced to your notice, and myself as a sufferer, at a previous meeting of the Association.

Hospital Reports.

BRISTOL ROYAL INFIRMARY.

CASES

Reported under the Terms proposed by the Association.

By NIL DESPERANDUM.

Extravasation of Urine.

JAMES CHAPPLE, aged 42, admitted to the Bristol Royal Infirmary, March 20th, 1851, under the care of

Mr. Harrison, with extravasation of urine. He states that he has not had any difficulty in passing water until the last twelve months, but for the last week has been passing it in drops. Scrotum began to swell three days ago, and became red and very painful.

Present condition.—Scrotum is much swollen and of a livid colour; the integuments of the abdomen up to the umbilicus are also of the same colour; there is no appearance of any abscess in the perineum; countenance anxious and pinched; skin clammy; pulse 108, weak, and intermittent; tongue brown. He was placed under the influence of chloroform, and Mr. H. opened the membranous portion of the urethra and made several incisions into the infiltrated parts. (This man had a congenital deformity, the opening or meatus urinarius was situated inferiorly and at the base of the corona glandis.) Ordered brandy to be given frequently.

March 21st.—Has taken sixteen ounces of brandy; but his pulse is weaker and intermits; tongue is browner; scarcely any heat of surface. These typhoid symptoms increased and he died on the following day.

Secitio cadaveris.—On reflecting the integuments of the abdomen, the cellular tissue was found to be sloughed for a considerable extent; there was a large quantity of ill-formed pus present. The kidneys, ureters, bladder, and a considerable portion of the urethra were taken out carefully together. The stricture was at the bulb; an abscess had formed behind the stricture external to the urethra, and had apparently opened into the canal. The bladder was evidently much diminished in capacity, but the coats were much thickened—to the amount of three quarters of an inch; the mucous membrane was rough; the left kidney was lobulated and not much more than half its natural size; the cortical portion was indistinct, almost obliterated. The parenchymatous portion contained several abscesses. The right kidney contained pus, but was not involved to the same extent. There was a calculus almost completely obstructing the gall-duct, the bladder being much distended. The other organs were healthy.

Remarks.—This is one of those cases of stricture of the urethra, in which, if extravasation of urine takes place to such an extent as in this instance, the chances of recovery are very small, on account of such severe structural disease of the kidneys being present. Liston speaks of the wonderful recoveries that patients often make in this affection, when free incisions are made and stimulus is freely given, (the treatment that was adopted in this case,) and gives an example in which the patient was almost moribund, when the above treatment was practised, and was followed by recovery. He states afterwards, that the stricture was got rid of, and restoration to perfect health followed. This, I think, shows that there could not have been any organic disease of the kidneys, at least to any great extent.

Extravasation of Urine.

JAMES CHAPLIN, aged 40, admitted at half-past seven, P.M., March 24th, 1852, under the care of Mr. Prichard,

for extravasation of urine. He states that he has had difficulty in passing water, and diminished stream for the last 20 years. Three years ago an abscess was formed in the perineum which broke, leaving a fistulous opening. During the last fortnight the difficulty in passing water had much increased, and four days ago swelling and tenderness of the perineum and scrotum came on, attended with severe constitutional symptoms, when he applied here as an out-patient two days since, but he did not show the swelling in the perineum. He had some medicine given him, which somewhat relieved his symptoms. Yesterday the swelling in the perineum broke.

Present condition.—Scrotum red, and swollen as large as a child's head, with a small slough inferiorly; there is a slough protruding from the opening in the perineum by the side of the anus; and above and distinct from this there is a large swelling, evidently containing pus. The penis and abdomen are not at all affected; feels much depressed. Mr. Prichard opened the abscess, and evacuated rather a large quantity of pus mixed with urine. Two incisions were made in the scrotum.—R. Tinct. Opii, m. xx. Statim. Poultice to scrotum. To have full diet and a pint of beer daily.

March 25th.—Much relieved; slept well; urine comes freely away *per urethram*, also through the perineum; scrotum is a little reduced in size.

26th.—Scrotum is considerably smaller; the slough is larger and is separating; passes water *per urethram*, in a good-sized stream; pulse 96; tongue clean.

27th.—Slough has separated from scrotum, which is reduced to its normal size; the slough was evidently an obstacle to the infiltrated urine draining away; urine continues to pass through the perineum to a slight extent.

31st.—Urine passed through urethra entirely; cavity in scrotum is granulating.

The wound in the scrotum gradually closed, and he was discharged cured; being able to pass water better than he had done for many years. When the cavity in the scrotum was in process of healing, he had two attacks of retention of urine, evidently spasmodic, as a full-sized catheter was passed on each occasion. Mr. Bransby Cooper, in his works, speaks of abscess in the perineum being the result of stricture, even when the obstruction is not sufficient to produce retention; and goes on to state that these abscesses result from the dilatation of the urethra behind the stricture, producing ulceration of its structures, and consequent infiltration of urine. I think that this is one of those cases, in which abscess in the perineum came on without there being an impermeable stricture present, and which caused such an obstruction to the passage of the urine, that extravasation of urine was the result.

The same author, in speaking of the treatment of abscess in perineo, recommends that a free opening should be made, and the catheter passed, if possible, along the natural passage of the urethra into the bladder; but that the passing of the catheter should never be attempted, until the abscess be opened, as the accumulation of matter itself might cause a considerable

impediment to the passage of the instrument; and he gives a case in which he was sent for to see a patient who had retention of urine. Symptoms being urgent, he attempted to pass a catheter, but not succeeding, he examined the perineum, and found a tumour of considerable size; into this he made an incision, and evacuated a quantity of pus and urine. As the patient stated that he had been the subject of stricture for many years, Mr. Cooper says:—"I considered it better to open at once the membranous portion of the urethra." He therefore passed a female catheter into the bladder, and drawing off the urine relieved the retention; he next passed a male catheter along the natural passage of the urethra, as a preliminary to the division of the stricture, when, to his surprise, the instrument readily passed on into the bladder. He says:—"If I had attempted to pass the male catheter before I had divided the membranous portion of the urethra, I should have found the latter operation altogether unnecessary." In the case I have related, I think the fact of the man passing water freely *per urethram* the day after the abscess was opened, bears out the view that the extravasation was caused by the obstruction of the urethra by the abscess.

Amputation of both Thighs: Recovery.

WILLIAM FAULKNER, aged 22, was admitted May 12th, 1851, at 12 at noon, under the care of Mr. Clark. The right leg was torn off at the knee-joint, and there was a comminuted fracture of the femur in the lower-third of the same limb; the left knee-joint was laid open, the femur being dislocated inwards; the leg and thigh were only held together by means of the soft parts at the external part of the knee-joint. He received these severe injuries from being caught up by the shaft of a steam-engine. He was conscious when brought in, but in a state of considerable collapse; in a quarter of an hour after admission was insensible, the pulse being scarcely perceptible, and the skin very cold. Brandy to be given frequently.—One P.M. Pulse could be felt, but very weak and slow. Scarcely any bleeding from the lacerated limbs. Ordered bottles of hot water to the axillæ.—Three P.M. Pulse a little stronger. Appears to be suffering great pain. He has taken 20 ounces of brandy since admission. *Operation*; Mr. Clark removed the right thigh above the point of fracture. There was but little bleeding, and only two ligatures were required. The muscles were much tumefied. The left thigh was then removed at the lower part of the middle-third. Only one ligature was required. On the completion of the operation, the pulse was scarcely to be felt, although he was taking brandy almost continually during its performance. However, from this time to eleven P.M., his pulse very gradually improved, but was exceedingly weak. He took twenty drops of tincture of opium at nine P.M. Up to about twelve at midnight he lay moaning, and did not recognise his friends when he became conscious. May 13th, 1 A.M.—Has vomited several times. Refuses to take any more brandy. Pulse a little stronger. He complains of great pain, and the stumps jump very much. There has been no secondary hæmor-

rhage.—Five A.M. Is very restless, from the stumps being very painful. He has taken a little beef-tea, and some milk. The bandages were loosened, which has given him ease.—One P.M. Much improved; pulse firmer; not in much pain. Skin has acted freely.

14th.—Looks much better. Pulse stronger 120; great thirst; skin acts profusely. He takes brandy, beef-tea, and milk.

15th.—Skin feels hot; but does not perspire. Pulse is moderately strong, 100. Bowels not moved since admission. The stumps are very painful, and there is a considerable discharge of fætid pus from them. Lemonade *ad libitum*.—R. Liq. Opii Sed. m. xxv.; Mist. Salinæ, oz. j. Ft. haust statim sumend.

16th.—The stumps were dressed to-day, and found to be discharging freely. Pulse 96, soft; skin perspiring.

Sept. 9th.—He left the Infirmary.

This case is interesting as showing what severe injuries may be recovered from, when the patient is of a strong constitution, and has been temperate in his habits; it also illustrates the absolute necessity there is for the profuse administration of stimuli in cases of such extreme collapse. In this instance, I think the man owed his life to the free exhibition of brandy. He was under treatment some considerable time, on account of exfoliation of the bone in the right stump, and a collection of matter amongst the muscles. At the operation there was a good deal of difficulty in covering the bone, from the engorged condition of the soft parts; this arose, no doubt, from the thigh being much contused at the time of the accident, as the femur was fractured on that side. I saw this patient some few weeks back, and his stumps were perfectly well, and he was wearing his wooden legs without the slightest discomfort.

LEICESTER INFIRMARY.

CASES

Reported under the Terms proposed by the Association.

By DR. JOHN BARCLAY.

Scirrhus Condition of the Œsophagus.

A CURIOUS coincidence in connection with the following cases happened in their being both admitted on the same day, November 11th, 1851, and dying on the same day, January 12th, 1852.

Valentine Adams, of Leicester, aged 59, labourer, widower, admitted November 11th, 1851. He states that he has been ill six months, and dates his illness from an attack of "inflammation of the stomach" which he had in the month of June, 1851. He is much emaciated, but has no malignant appearance; he is very nervous, but has no headache, and complains of no pain anywhere; he has palpitation, but the sounds of the heart are normal; he has no cough, and the lungs, on examination, are quite sound; he has no sickness; his appetite is good, but he cannot

swallow solids; he never vomits; his tongue is very foul, and coated; he has a good deal of flatus; his bowels are open; the urine contains no albumen nor sugar, is acid, specific gravity 1020.

On examination of the abdomen it is not much sunk. There is no fulness nor hardness anywhere to be detected.—Capt. ter die Acid. Hydrocy. (Scheele's), m. ij.; Pot. Bicarb., gr. x.; Tinct. Hyoscy., m. xx.; Infus. Calumb., oz. iss.

November 14th.—Much the same. Can swallow beef-tea and slops.—P.

16th.—App. Scrob. Cordis Emp. Canthar.

20th.—A little better since the blister.—P.

22nd.—Hæmatemesis to the amount of two pints to-day. Blood clear, dark, and venous.—Capt. ter die Arg. Nit., gr. 1-6th; Alum. Exsicc., gr. x.

23rd.—Pulse feeble; tongue still very foul.

26th.—Hæmatemesis again, but not to such an extent as formerly.—Capt. quartis horis Acid. Gall., gr. v.; Pulv. Tragac. Co., gr. v.

30th.—Much better. Tongue quite clean; pulse natural, but feeble.—Rept. Vesicat. Scrob. Cordis.

December 4th.—Better. Tongue still clean, can swallow a little better, and gains flesh. No more blood.—R. Quinæ Disulph., gr. j.; Acid. Sulph. Dil., m. v.; Mist. Camph., oz. iss. Omit. Acid. Gall.

17th.—Much better. Gaining flesh, tongue clean, urine natural.

30th.—Continues improving; can swallow better. Blister repeated.

January 4th, 1852.—An examination with the probang shows an obstruction which it was impossible to overcome, just above the cardiac orifice of the stomach. Tongue becoming foul again. He is worse and weaker. The probang to be passed every two days. Bowels open; urine natural.

7th.—Worse. Cannot swallow anything. A table-spoonful of cold beef-tea seems to disappear, after long waiting. He expectorates about half a pint of glairy saliva daily.

11th.—Worse. Tongue very foul; pulse very slow, and feeble; emaciation extreme; the ribs very much projecting over the abdomen; the cartilages apparently ossified, and the abdomen a deep concavity, in which, however, no hardness is to be felt, except in the course of the colon, probably from the lodgement of fecal matter.

12th.—Died.

Post-mortem examination, twenty hours after death.—

Emaciation extreme; the whole of the adipose tissue absorbed; heart and lungs healthy; stomach full of fluid, like gruel. A hardness was felt about three inches above the stomach, in the course of the œsophagus. It did not involve any other tissues, but was in close connection with the arch of the aorta. When dissected out it was seen to be a ring of cartilaginous hardness, involving the whole circumference of the œsophagus, in which the muscular coats were lost. There was an appearance of reproduced tissue where the mucous membrane had been abraded, above the stricture. The passage was contracted, so as to

admit only with considerable force a common-sized catheter. The gall-bladder empty. All the other viscera were healthy, but very bloodless. The colon was filled with lumpy scybala.

JOHN WRIGHT, of Leicester, framework-knitter, married; admitted November 11th. He has been ill two months. His complaint commenced with pain in the left side of the abdomen, and constant vomiting of food and matter like coffee-grounds; he is considerably emaciated, and has a very marked appearance of malignant disease. He has no headache, nor pain anywhere except in the abdomen; he has no cough; slight palpitation; pulse natural; his appetite is good, but capricious; he has much flatus; frequent pyrosis; his tongue is clean; he vomits most of his food, without retching, about an hour after taking it; he never has had hæmatemesis, but frequently vomits altered blood; he has much griping pain, and cannot lie on the right side; the bowels are very costive; the urine is normal; there is slight fulness in the left hypochondrium, but no hard nodules to be felt.—Capt. ter die Mist. Bismuthi; Mist. Mag. cum Rhei, utrq. dr. vj.

November 14th.—No better; emaciation proceeding rapidly; vomited matters consist entirely of food; the abdomen very lumpy.

16th.—No better; vomiting continues; a little fulness in the region of the pylorus; bowels open.—Capt. ter die Creasoti, m. j., formâ pilulæ.

20th.—No better; bowels open; sickness continues.—Omit the creasote pills.

23rd.—A little less pain.—To have only nourishing liquids and wine.

26th.—No improvement.

30th.—The medicine gripes him, he says; bowels rather purged; stools natural; appetite gone; a little fulness and hardness to be felt at the pyloric extremity of the stomach; he is very low; pulse very feeble, and slow.—To have gin in place of wine.

December 4th.—Better, except the pain in the bowels, which is occasionally lancing.—App. Emplast. Sinap. alt. noctibus.

14th.—Worse, vomiting stuff like coffee-grounds.

17th.—Worse; gin heats him, so to be omitted.

27th.—Worse; bowels natural.

31st.—Emaciation proceeding rapidly; eyes much sunk; pain much aggravated on pressure over the tumour; decubitus on the back; urine natural; stools natural.

January 2nd, 1852.—Tongue foul; pulse failing; much distension of the bowels from flatus.—Capt. ter die Pil. Galb. Co., gr. x.

7th.—No relief; pulse almost imperceptible; pain in abdomen excessive.

11th.—Evidently dying, and almost unconscious.

He died on the 12th.

Post-mortem sixteen hours after death.—Thoracic viscera healthy; the whole of the bowels and their peritoneal coat in a most advanced stage of inflammation, and all glued together with exuded lymph; the whole of the intestines distended with flatus, and much

injected; no fluid in the peritoneal cavity; the pyloric orifice of the stomach was enveloped in a mass of scirrhus, of cartilaginous hardness, about the size of a bantam's egg, the passage almost completely obstructed, so that a common catheter could only be pushed through with difficulty; there was much thickening of other parts of the intestinal canal, but no other scirrhus deposits were found.

Provincial Medical & Surgical Journal.

WEDNESDAY, JULY 21, 1852.

How greatly private interest sways the election of officers to hospitals is a fact too well known; but we were scarcely prepared to find so gross an instance of favouritism as is about to be perpetrated at the Bethlehem Hospital. Our readers are aware, that in consequence of some disclosures reflecting on the management of this institution, it was determined for the future to appoint a Resident Physician at a handsome salary, who was to be responsible in the main for the medical supervision of that noble establishment. This doubtless appeared to every one a most eligible proposal; and the satisfaction was enhanced by the open way in which the best qualified men in the kingdom were invited to become candidates. Will it then be believed, that after all, this apparently just proceeding is entirely humbug, and that after putting numerous gentlemen to a great amount of expense and inconvenience, on the faith that merit alone would influence their decisions, the Governors are about to confer the appointment upon a certain individual, not because he is found to be superior to his competitors, but because he is fortunate enough to be connected with one of the most influential members of the Board. That such, however, is the fact, is evident from the subjoined letter from Dr. ROBERTSON, one of the three candidates chosen out of the total number for ultimate selection. We are not surprised at this gentleman's determination, but on the contrary, we give him credit for the manly manner in which he has repudiated the farce in which he would have been made to play an inglorious part. Dr. ROBERTSON's letter is to the following effect:—

"To the Governors of the Royal Hospital of Bethlehem.

"My Lords and Gentlemen,—With reference to my printed letter of the 17th instant, offering myself as a candidate for the office of Resident-Physician to your

Royal Hospital, I would now desire to acknowledge the high sense I entertain of the honour conferred upon me in the return of my name by your Committee, as one of the three candidates selected for election.

Having, however, ascertained that a number of the Governors, such as practically to determine the election, were pledged to the support of one candidate before they had an opportunity of judging of the claims of the other two recommended by their Committee, I deem it more respectful to the Court at once to withdraw my application.

I have the honour to be,

&c., &c., &c.,

C. LOCKHART ROBERTSON, M.D.,

Caius College, Cambridge.

We do not, in thus espousing the cause of Dr. ROBERTSON, intend for one moment to insinuate that Dr. W. C. HOOD, the gentleman decided upon, is not in every respect eligible to the responsible office to which he is to be, or it may be, is appointed, but we protest against the manner in which the decision has been made, as in the highest degree detrimental to the honour of the board of Governors, and insulting to the other candidates. If it were all along their intention to elect the Aldermanic candidate, as it clearly has been, it was a most unworthy proceeding to hide that intention under the solemn farce of appealing to the talent of the country at large. They may boast of their exemption from Government inspection, but assuredly, after this exhibition of their mode of doing business, the public will agree with us, that though there may be institutions which may be safely left free from surveillance, the Royal Hospital of Bethlehem is not one of them.

No inconsiderable excitement has been produced in the profession, by the impression that the unfortunate Mr. PASCOE had been condemned to a felon's punishment unjustly, and mainly in consequence of the unsatisfactory and altogether erroneous evidence of one of the medical witnesses. We did not at the time take up the matter for two reasons—firstly, that the cause of the culprit had been ably and generously advocated by our contemporary, the *Medical Times*; and secondly, because we felt convinced that there must have been some stronger proof of the wretched man's delinquency that had not come before the public, and that he was not transported solely because one gentleman had too hastily stated that savine was now never given by medical practitioners for truly medical

purposes. The result of further inquiry has confirmed our suspicions, as it turns out that abortion was wilfully and knowingly induced, and, therefore, that the convict had justly earned his melancholy fate. We do not, however, on this account, regret the agitation which has been unnecessarily made respecting the case, for if no other result has accrued, it has at least afforded an opportunity for the exhibition of that kindly sympathy which our profession is ever willing to extend to the unfortunate among its members.

Proceedings of Societies.

LANCASHIRE & CHESHIRE BRANCH.

THE sixteenth Anniversary Meeting of the LANCASHIRE AND CHESHIRE BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION was held at the Medical Institution, Liverpool, on Wednesday, the 30th of June. At the commencement of the proceedings, W. S. Turner, Esq., of Manchester presided, and there were also present—R. Bickersteth, Esq., J. Nottingham, Esq., James Petrie, Esq., Jas. Turnbull, M.D., John Burrow, Esq., — Dismond, Esq., P. Macintyre, M.D., D. Paterson, Esq., Ellis Jones, Esq., R. Dundas, M.D., Edward Batty, Esq., Joseph Dickinson, M.D., W. H. Duncan, M.D., John Halliday, Esq., J. Eccleston, Esq., T. Cameron, Esq., W. Eddowes, Esq., and — Edney, Esq., Liverpool; Thomas Turner, Esq., Edmund Lyon, M.D., Samuel Crompton, Esq., G. Southam, Esq., John Hatton, Esq., (Honorary Secretary), Manchester; J. A. Pearson, Esq., Woolton; John Sharp, Esq., Warrington; A. O. Leete, Esq., Newton; G. Daglish, Esq., Wigan; G. Mallett, Esq., J. Black, M.D., Bolton; and A. M. Dunstan, Esq., of Holmes Chapel.

THOMAS TURNER, Esq., having been called to the chair, said it fell to his lot to preside over the meeting of this Branch of the Provincial Medical and Surgical Association, which was held at Manchester last year; and he believed it was usual that the retiring President should take the chair in the first instance, in order to introduce to them the gentleman selected to be their President that day. He alluded to his friend, Mr. Bickersteth. That gentleman was so well known to them, and so distinguished as a surgeon, as to supersede the necessity of any observations on his part. (Applause.) Feeling as he (Mr. Turner) did that the Presidency of this Association involved not only points of honour, but great responsibility, he thought it was the duty of every man who might be called upon to fill that office, especially if he happened to be a senior member of the profession, to weigh well the remarks he might have to make upon subjects connected with the profession. He felt that this was the more imperative upon himself, in consequence of a misunderstanding which had taken

place relative to what he said at the Manchester meeting, and which had exposed him to the lash of one of the medical critics. He was not deserving of the imputation cast upon him; but he thought he might avail himself of this opportunity to contradict the impression made upon the minds of some individuals that he was favourable, or, at all events, not unfavourable, to some of the monstrous views entertained of medical doctrine in the present day. It would be remembered by such of the members as were present on that occasion that he took the opportunity of stating that it was the tendency of many minds to fall into extremes; and they saw that such was the marked feature of the present day, not only in connection with their own profession, but with regard to every other profession and pursuit in life. He stated that whilst they condemned extreme views, whether hydropathic, homoeopathic, or whatever else it might be, that it was well to look to themselves, and ask themselves the question whether they did not, in consequence of individual opinion, doctrine, or belief, as to the seat of disease and an individual system of treatment, expose themselves equally to the charge of empiricism, as other men did who fell into extreme views, whether in reference to theory or the practice of the profession. They must rank amongst empirics all men who were individual in their views. For example, how prone each of them might be to form individual opinions as to the seat of disease. One man might be led away by the belief that all diseases are referable to the brain, the heart, or the lungs; a second would refer it to the digestive organs, and another to the spine; and the cases which fell under their observation would be regulated according to the individual opinion of the practitioner in respect to what he had discovered, or believed he had discovered, as the common source of disease. This was falling under their observation every day; and therefore if an individual was so biased in favour of a particular view, he must fall under the charge of empiricism. How prone they all were to fall into the use of a particular form of medicine; iodine and cod-liver oil for instance. This was the besetting sin of the present day. The medicines to which he alluded were, no doubt, of great use; but they were employed empirically in a great number of cases. Look again at the abuse of chloroform, which was used in certain operations more than it ought to be. His opinion was, that in order to maintain themselves unblemished, and beyond the reach of criticism, it was necessary that they should consider the practice of medicine and the practice of surgery, upon sound scientific principles, divesting themselves of any individual view—to consider them as based upon the knowledge of science, of human nature, and of the diseases incident to the human body. (Applause.) When he stated that he was educated in the school of Sir Astley Cooper it was a sufficient reply to the charge made against him that he was favourable to homoeopathy. (Hear, hear.) He had thought it right to make these remarks, in order that no erroneous impression might rest upon the mind of any one; but those who knew him would be per-

fectly aware that there was no man less given to individual opinions in matters of physic than himself. (Hear, hear.) In conclusion, he said he had great pleasure in resigning the chair to Mr. Bickersteth. (Applause.)

Mr. BICKERSTETH said, that as this was his first appearance at any meeting of their Association, they must not expect any observations from him. Although he had not yet taken an active part in their proceedings, he had been a member of the Society some years. (Applause.) He begged to call upon the Secretary to read the report.

Mr. JOHN HATTON, the Honorary Secretary, then read the

Report of the Council.

"The Council of the Lancashire and Cheshire Branch of the Provincial Medical and Surgical Association have to present to the members their annual Report, which, however, comprises very few details of any important account; the routine transactions, in correspondence with the Parent Association, almost constituting the sum of the last year's proceedings.

"In accordance with the wish of the Central Council at Worcester, a special general meeting of this Branch was held at Newton, on the 11th of February last, for the purpose of considering the "Proposed New Bill (originating with the Central Council of the Association,) for the Regulation of the Medical Profession;" at this meeting the subjoined resolutions were unanimously passed:—

1.—"That this meeting of the Lancashire and Cheshire Branch of the Provincial Medical and Surgical Association, after maturely considering the 'Medical Bill' referred to them by the Worcester Council, and published in the *Provincial Medical and Surgical Journal*, is of opinion that such Bill faithfully represents the principles of Medical Reform so long advocated by the Association, and is worthy of the cordial support of every member of that body.

2.—"That this meeting recommends the framers of the Bill to persevere in their endeavour to pass it into a law, with such alterations in the details as circumstances may require, and trusts that the members of the Association will exert themselves in their several localities to induce members of Parliament to take an interest in the passing of this measure, so important to the welfare of the profession, and of the public.

"Besides the formal adoption of these resolutions, a prolonged and interesting discussion ensued upon the several clauses of the proposed Bill, the result being, that with some unimportant exceptions, the entire document elicited the fullest approbation.

"There was evinced an especial approval of the proposal for a Provident Fund, and of the uses to which it was proposed the surplus provided by the 19th Clause should be applied.

"The Council take this opportunity of soliciting from the Branch some formal and definite approval of the course pursued by all that is honourable in the profession, with respect to homoeopathy and to those practitioners who in any way compromise themselves by countenancing, directly or indirectly, this pernicious and degrading system of quackery.

"The Council have to congratulate the members on the grant of a Supplementary Charter to the Royal

College of Surgeons of England, which, although it may not comprehend every improvement in the constitution of the College that had been sought, remedies, however, the more substantial grievances that had been complained of.

"The successful progress of a Medical Benevolent College, proposed by Mr. Propert, is also a matter of congratulation. Surprise has been manifested that nothing has been done by this Branch towards promoting the Institution.

"The subject of a New Charter for the College of Physicians is now before the profession for discussion; it will be for the members to decide whether, at the present meeting, any expression of opinion with relation to it shall take place.

"*Finances.*—At the last anniversary there was a balance in favour of the Association of £4. 8s. 9d. Since then the receipts have been £11. 10s., and the expenses £8. 17s. 2d., which leaves a balance of £7. 17s. to the credit of the Branch. The Council recommend that a donation of £5 be given to the Benevolent Fund, but this can only be done by a vote of the general meeting at present assembled."

Dr. DICKENSON said that allusion was made in the report to the Medical Benevolent College, and he might state that the Liverpool practitioners had not been backward in their subscriptions. They had contributed £150 already, and they looked with some degree of anxiety to Manchester, seeing that none of the eminent gentlemen there had come forward to support the fund.

Mr. SOUTHAM stated that the subject had not been overlooked, and he believed that after the elections were over an appeal in behalf of the fund would be made in Manchester.

The PRESIDENT said that he should be very glad to hear that such was the case.

Mr. MALLETT, of Bolton, moved that the report be adopted and transmitted to the Secretary of the Provincial Medical and Surgical Association for publication in the *Journal*, together with the proceedings of this meeting.

Mr. PATTERSON, of Liverpool, seconded the motion.

Dr. DUNCAN asked, did that sanction the payment of £5 to the Benevolent Fund?

The SECRETARY said it did.—The motion was then unanimously carried.

Dr. DUNCAN had great pleasure in moving the thanks of the meeting to Thomas Turner, Esq., and the Council for their services during the past year.

Dr. MACINTYRE seconded the motion, which was carried by acclamation.

The SECRETARY said, that last year but one they tried to get up a meeting at Preston, but without success; and it was thought better that they should alternate between Liverpool and Manchester. If this meeting came to that conclusion of course their next meeting would be held in Manchester.

Mr. TURNER thought it would be desirable to consider whether Chester and Lancaster, being county towns, should not be visited,

The SECRETARY said that in Chester they had only

two or three members, and in Lancaster they had not one. He had waited upon Mr. Howitt when he was Mayor of Lancaster, and the conclusion came to was, that they would not get any support there as the profession in Lancaster had a Society of their own.

Mr. PEARSON said the subject of holding a meeting at Chester was gone into at considerable length when Dr. Edwards lived there, but it was not thought advisable. He considered, however, that it would only be paying Chester a proper compliment if they were to go there. He moved that their next meeting be held in Chester.

Mr. TURNER seconded the motion.

In answer to a question, the SECRETARY stated that he believed there were four or five gentlemen belonging to the Parent Association in Chester.

Mr. SHARP suggested that the question should be left with the Council to decide, which was eventually agreed to.

Mr. CROMPTON moved that Dr. Black of Bolton should be president next year; and the proposition having been seconded, was unanimously agreed to.

Dr. DUNCAN suggested, that as Chester would probably be the next place of meeting, they should appoint a Chester gentlemen as one of their vice-presidents.

Mr. ELLIS JONES proposed Dr. Phillips Jones of Chester.

Mr. BURROWS seconded the motion, and it was agreed to.

Dr. MACINTYRE was proposed as the other Vice-President, but having been so recently in office, he declined the honour in favour of Dr. Dundas, who was elected accordingly.

The SECRETARY proposed the following gentlemen as new members:—A. W. Dumvill, Esq., Manchester; Henry Pritchard, Esq., West Derby, Liverpool; Thos. Eccleston, Esq., County Asylum, Rainhill; James F. Pennington, Esq., Ashton-in-Mackerfield; Lorenzo Edward Desmond, Esq., Edge Hill, Liverpool; John Latham, Esq., Wigan, Lancashire; who were unanimously elected.

The PRESIDENT then said he had received a letter from Dr. Cowan of Reading, who proposed that the *Journal* should be published weekly and in London, instead of fortnightly, at Worcester. Every effort should be made to render the *Journal* worthy of the Association, and he hoped to propose some practical plan for its improvement. He was desirous of ascertaining the opinion of the Association upon the subject.

Mr. BURROWS thought that it was questionable if the funds of the Association would allow of a weekly publication, as the *Journal* was reduced to a fortnightly issue in order to save postage. He did not see that it would be any material advantage to publish it in London, unless the residents there might be disposed to furnish communications, and it might perhaps be got up at a less cost. Their great object should be to get valuable information on medical topics.

Dr. BLACK said this was a subject which would lead to a great deal of discussion, and required mature consideration. There would be a variety of opinions, and he himself was in favour of the publication still

being provincial. He should like it to be published either in Manchester, Birmingham, or Liverpool, but it was not to be expected that they could come to any conclusion at this meeting.

Mr. TURNER agreed with Dr. Black that the *Journal* should still be provincial, both in name and publication.

Mr. CROMPTON said it appeared to him that Dr. Cowan's proposition was perfectly legitimate, and he thought they ought to say whether the *Journal* was edited with that degree of ability which was satisfactory to the members. They knew that the cost of the direction of the *Journal* was very large; the Editorial expenses were considerable, and these were questions which should come under consideration. It would be for the Council, after taking the opinion of the members, to determine what steps were desirable.

The PRESIDENT stated, that Dr. Cowan had given notice of a motion on the subject, to be introduced at the next general meeting of the Association. He thought that the best way would be, for some gentleman to move that the *Journal* was satisfactory.

Dr. NOTTINGHAM said they should know the present cost, and then ascertain what expense the alteration would involve. The financial question was the most important.

Mr. ELLIS JONES said that Dr. Cowan merely wished to have the opinion of this meeting as to the desirability of altering the place of publication. The decision would be left to the general meeting.

Mr. TURNER said, that if they went to London they would be considered as putting themselves in antagonism with the metropolitan journals. He thought with Dr. Black, that it would be desirable to have the *Journal* published in one of the large towns, and whether that would be advantageous, was the question they had to decide.

Mr. MALETT thought it very desirable, if the funds would permit, to revert to the former plan of publishing the *Journal* once a week. When that was the case, they had also a large volume, well bound, instead of, as at present, a small volume, unbound. It appeared to him that there was some error in the management of the funds.

Mr. CROMPTON remarked that the Editorship for a leading article and retrospect cost £10; and he really thought the Editor was very handsomely paid.

Dr. BLACK had made investigation, and found that the publication of the *Journal* in Worcester cost a deal more than it could be done for in other places.

Dr. DUNCAN said that the question was one requiring more mature consideration than they could give it at that meeting. He certainly thought that the *Journal* might be improved.

Mr. CROMPTON: Would it not be better to express an opinion at this meeting that the *Journal* was unsatisfactory? He would second such a motion.

Mr. TURNER thought an opinion would be formed as to the general impression from what had transpired; and a decision could be come to at the Oxford meeting.

The discussion then terminated.

Mr. CROMPTON then read the following paper, contributed by Mr. Beardsley, of Ulverston:—

A few Remarks on the Treatment of the Suppurative Stage of Burns by Unguentum Gallæ.

The large ulcers remaining after very severe, and more particularly, extensive burns, frequently prove tiresome and difficult to heal; but I think they are often more so than they need be from the application of unguents, &c., not calculated to work a *speedy* cure, as the more rapid the cures the less likelihood is there of there remaining unsightly and hideous cicatrices, and other malformations witnessed occasionally after these accidents. I have seen very many of these cases of severe burns in colliery practice, produced by the explosion of gages in coal mines, and every practitioner acquainted with like cases knows how extensive they sometimes and most frequently are, and ulcers are not uncommonly resulting of even square feet in size, and I have seen the whole surface of the back completely denuded, and a large suppurating surface remaining; and I have seen it heal without the least cicatrix whatever by the remedy I wish to draw your attention to. I put no faith whatever in the application of unguents containing preparations of chalk, zinc, magnesia, calamine, &c. I think the principle of their application wrong. The best remedy after the suppurative stage is thoroughly established, is an ointment made of Pulvis Gallæ, dr. j.; Adips, oz. j. With this the formation of new skin takes place rapidly, and ulcers of very large size I have seen quite healed in a few days. I am not prepared to explain in what way this application succeeds so well, but I mention the fact, that others may adopt it, and I am quite sure it will never be laid aside for another remedy at the particular juncture for which it is recommended. No doubt it has a chemical action upon the secretion of the granulations, which leads to so speedy a formation of new skin. I have also used tannin and gallic acid, with similar results; but as a general rule I prefer the gall ointment alluded to above. Particular care should be taken in not using powdered galls that look full of black specks. That, I think, is adulterated with pepper, as it proves too stimulating; but if pure, it is cooling and agreeable, and in every case, (and I have seen it applied in hundreds,) I have realised a happy result.

Mr. CROMPTON, before he sat down, begged to move a vote of thanks to Mr. Beardsley, for his communication.

Dr. NOTTINGHAM seconded the motion, which was carried by acclamation.

Dr. DUNCAN said he had not tried the remedy; but thought it was one of great promise.

Cinchonism in Typhus.

Dr. DUNDAS then said, before I proceed to lay before you the notes of two cases of continued fever, lately treated in the Liverpool Northern Hospital by large doses of quinine, a few brief observations on the question of cinchonism, and of its power to arrest the course of the continued fevers of this country, might perhaps prove interesting to you.

Some, at least, of my brethren now present are

already aware that not long since I submitted this doctrine, with the evidence on which it is based, to the judgment of the profession; and although sufficient time may not have yet elapsed to warrant their final decision on a doctrine so directly opposed to the medical authorities in this and other countries, I trust you will be disposed to admit that the decided facts I am about to lay before you afford evidence, neither slight nor inconclusive, in support of the efficacy of the treatment I have advocated, and the soundness of the theory on which that treatment is based.

It would be altogether out of place to enter, here, on any of those vexed questions which have so widely divided the most eminent men in this and other countries on the subject of fever. Still it is necessary that I should briefly state the broad principle on which my own views on this subject are founded,—namely, the essential identity of fever; and that its varieties are determined by the influence of climate, temperament, different modes of living, the sanatory conditions of the population attacked, and numerous other agencies. This view has been forced on me by the observation of fever on a large scale, not only in the different countries of Europe, but in various regions of America, the West Indies, and Brazil, in the discharge of my duties as an Army-Surgeon, and in private life. I would here observe that there is one remarkable fallacy which I find to pervade the great body of the profession in England, and inculcated in the writings of some of our most distinguished authors,—namely, that typhus fever is unknown in hot climates. Nothing can be more untrue. The intermittent and remittent fevers of hot climates do frequently merge into genuine typhus, and into every variety and shade of typhus; whilst conversely the continued fevers still more frequently pass into or assume the intermittent form. These, gentlemen, are the broad facts which first convinced me of the essential identity of the different varieties of fever; and the truth of this conviction has been since established by another great fact,—namely, that all the several varieties and types of fever are under the control of one and the same agent; and I need scarcely observe to an assembly like the present that the results of treatment in numerous maladies will serve more clearly to identify or disconnect diseases than the most careful observation of symptoms, or even of *post-mortem* appearances.

It will also, I believe, be readily admitted, in so far as regards the treatment of fever, that we have advanced scarcely a single step since the days of Hippocrates; each succeeding writer has merely transposed, or played on “the words” of his predecessor; whilst a grand fallacy appears to have pervaded almost all,—namely, that continued fever was a specific malady, and must, therefore, run a specific course; that, like small-pox, the disease could not be arrested. And this ill-founded hypothesis—for it scarcely merits the name of theory—sufficiently accounts for the “*expectante*” system, which, with some exceptions, has hitherto so generally characterized the treatment of continued fever in this and other European countries.

As regards the "cinchonising system," now brought forward, we ought, perhaps, after all, to be less surprised at the opposition it has encountered than at the extent to which it has been already adopted by the profession; and the more especially that, independently of other reasons, one of our leading authorities has long since declared that "in the continued fevers of this country bark might be erased from the list of remedies altogether;" and our standard work on materia medica states "that in febrile diseases, attended with a hot and dry skin, and a furred and dry tongue, quinine acts as a local irritant and stimulant, and adds to the severity of all the morbid symptoms;" whilst one of our most distinguished authors considers it *impossible* that "there can be any practitioner so *utterly ignorant* of his profession as to prescribe quinine in the early stages of fever, *under any circumstances!*" And all appear to adopt the dogma of Pitcairn, that "you cannot *cure* a fever." Now, gentlemen, in opposition to this celebrated and fatal maxim, and in opposition to the opinions of the high authorities I have just quoted, permit me to refer you to recent and undoubted testimony, which will, I trust, satisfactorily prove to you not only that you *can cure* a fever, but that you can, moreover, cure it, in the vast majority of cases, by the very identical agent which the above-named authorities have so especially and emphatically condemned.

In bringing forward the present question I have purposely put my own experience altogether aside; and I refer you alone to the necessarily impartial and unbiassed evidence supplied by St. Thomas's Hospital, the Liverpool Fever Hospital, the West Derby Fever Hospital, the Birkenhead Fever Hospital, the Drogheda Fever Hospital, and the Liverpool Northern Hospital, with that of numerous private practitioners of eminence in Liverpool and the neighbouring towns—as Messrs. Bainbrigge, Blackburn, Jones, Hensman, Pye, and Arnold, all of Liverpool; Mr. Gorst, of Rock Ferry; Mr. Glazebrook, of West Derby; Mr. Swinden, of Wavertree; Mr. Longton, of Southport; &c.; also within the last few days Mr. Woolseley, a medical student from Dublin, informed us at the Northern Hospital that the cinchonising system was now being tried with success at the Hardwicke Fever Hospital, in Dublin. I am also in a position to state that the great majority of the above gentlemen commenced the cinchonising treatment in doubt and hesitation, and yielded their assent to its truth on the sole ground of clear and conclusive experience. In this town the treatment was first publicly adopted by my talented friend, Mr. Eddowes, whilst attached to the Eastern Dispensary, and who, on his removal last year to the Liverpool Fever Hospital, there tested the system both *largely and carefully*; at the same time that my friend, Dr. Gee, the other able physician to that institution, watched, with the caution of a truly scientific observer, the progress and results of the treatment as carried out by his colleague; and only after lengthened and careful observation did Dr. Gee give in his adhesion to the cause of "cinchonism," and adopt it, universally I believe, in his own practice.

You will also, gentlemen, I am sure, be rejoiced to learn that the results of the experience, in such an extensive field, of two such able observers as Drs. Gee and Eddowes, will not be lost to science; and I am satisfied that when these results shall have been laid before the profession, the question of cinchonism in continued fever, will be conclusively set at rest.

Mr. Eddowes has indeed already reaped some *personal* advantage from his early belief in the power of cinchonism. Not long since he became himself the subject of an attack of typhus, and about the same time Mr. G., a promising young surgeon attached to the North Dispensary, was similarly attacked. Mr. Eddowes, strong in his faith, was brought immediately under the influence of cinchonism, and within forty-eight hours every unfavourable symptom had disappeared. On the fourth day he was going about his room, and on the tenth he removed from the Fever Hospital into the country for change of air. On the same day Mr. G. was interred. Cinchonism was proposed in Mr. G.'s case, but not adopted.

Having so recently brought the whole question before the profession, I shall not, gentlemen, occupy your valuable time, especially limited on the present occasion, with any further observations, nor shall I enter into any minute detail; my chief object being to place the broad principle before an assembly so highly qualified in every sense, to decide on its merits; and to request, as I do most earnestly, that you should rigidly test its value, and affirm or condemn it accordingly.

It should be stated that the present cases were admitted, as others are from time to time, for the purpose of practically illustrating the doctrine to the pupils of the hospital. The cases are always selected, and the notes taken, and the treatment carried out by the House-Surgeon, in the presence of the pupils, and without the slightest interference on my part. Mr. Edney is the reporter in the present instance, and I may add that, since I joined the Northern Hospital, Mr. Edney is the fifth House-Surgeon, all men of intelligence and professional experience, who commenced their investigations on this subject as sceptics, but ended as true believers.

The cases are as follows:—

Case 1.—Gilbert Smith, admitted 27th May, 1852, into the Northern Hospital, Liverpool, under Dr. Dundas, at nine P.M. So delirious that no history of his illness can be obtained from him. His countenance expresses great anxiety, and is of a deep purple hue; skin hot and dry; tongue dry, and coated with a dark fur; there are sordes about the lips and teeth; the abdomen is tumid, and he groans when it is pressed; pulse 112. To take ten grains of quinine every hour, and to have four ounces of brandy daily.

May 28th.—Has given the night nurse a great deal of trouble. He wandered about the hospital most of the night, but towards morning became quieter. He is now quiet and sensible. He says he is a sailor, and that he was taken ill at sea; but is not certain when, because he was "crazy;" that he had no medicine, and

was kept on low diet. His tongue is cleaner, there is not so much heat of skin, and he complains of slight thirst; the urine is not scanty, but high coloured; pulse 84; abdomen slightly tender.

29th.—Expresses himself as quite well. All symptoms have left him. Quinine continued in smaller doses.

June 4th.—He was out yesterday and went on board his own ship to see about his clothes. All his symptoms have returned—delirium, anxiety of countenance, furred tongue, hot skin. To take the quinine as before, ten grains every hour.

5th.—No better; complains of "cold shivers."—R. Ant. Tart., gr. ij.; Pulv. Ipecac., scr. j. To continue the Quinine as before, after the sickness ceases.

6th.—Expresses himself as quite "smart."

8th.—Discharged cured.

Case 4.—Richard Reynolds, aged 19, sailor, admitted 15th of June, under Dr. Dundas. States that he has been ill three weeks. He presents the following appearance:—Anxious countenance; great emaciation; eyes sunken; physical prostration and mental depression; dark dry tongue; great thirst and heat of skin; urine scanty, high coloured; pulse 120, small. There was slight delirium and great deafness. To take ten grains of quinine every hour, and have ten ounces of wine.

16th.—There is very little change. The tongue seems to be cleaning about its edges, and there is slight diaphoresis. Pulse 112, fuller. Great deafness. To take the quinine every two hours, and have an egg for dinner. The quinine was not taken regularly during the night.

17th.—There is great improvement. Excessive deafness and lassitude, are the only symptoms remaining. To take the quinine three times a day. A chop for dinner; wine discontinued; pint of porter ordered.

18th.—Convalescent.

Dr. DUNDAS said this was the last case admitted into the hospital. He took no active part in the treatment of the cases himself; but notes were taken for the benefit of the pupils.

The PRESIDENT asked how much quinine was given.

Dr. DUNDAS: Ten grains every hour.

Dr. DICKINSON: Might he ask,—Was there any mention in the cases cited of the state of the skin? There was, he thought, no eruption alluded to.

Dr. DUNDAS said there was no eruption in either of the two cases cited.

Dr. DICKINSON: Then upon what ground were they to come to the conclusion that it was true typhus?

Dr. DUNDAS: The symptoms and the length of time the patient was ill.

Dr. DICKINSON should doubt the existence of true typhus in such cases as those named. He had not heard of any symptom which was to his mind sufficiently conclusive. He had seen a great deal of fever for two years, in a dispensary and in a fever hospital; and the two cases cited were to him by no means satisfactory.

Dr. DUNDAS said there had been cases in which

there was an eruption, but he did not think that was necessary in order to constitute typhus.

Dr. DICKINSON: Might he ask what Dr. Dundas deemed essentially necessary to show the existence of true typhus fever? If they knew the grounds upon which they started, they would be able to advance more conclusively.

Dr. DUNDAS: I will read a letter from Dr. Kelly, of the Drogheda Fever Hospital, which may possibly abate Dr. Dickinson's scepticism on this point:—

"Drogheda, 3rd April, 1852.

"With regard to your original treatment of typhus fever, I must acknowledge myself a convert, as I have treated eight cases of the most severe description with the happiest results.

"I shall, however, enter into details of one of the most severe cases under my care.

"A poor farmer, named Pentony, aged 55, was admitted into hospital 16th February, had been ten days previously ill. The pulse was 120; the tongue dry and brown; he had constant muttering delirium. The respirations were forty; the skin covered with maculæ; the temperature 90°. He had involuntary discharges and subsultus tendinum.

"In two days after the administration of quinine (according to your directions) he was *convalescent*, and left the hospital in excellent health ten days after.

"In my opinion, such a happy result could not have been procured by any other treatment that I am aware of.

"In three of the fore-mentioned cases, four members of the families died in the houses from which my patients were removed; and in one case, the patient had been afflicted with chronic bronchitis for years, but it did not militate against the treatment.

"Trusting that such an invaluable improvement may be adopted by the members of the profession, and that my humble testimony may be of service in the trial of it,

"I remain, &c.,

"To Dr. Dundas, Liverpool."

"R. KELLY.

Dr. DICKINSON said, that when a great question was to be settled, the evidence ought to be beyond dispute.

Dr. DUNDAS agreed.

Dr. DICKINSON: Now, as to the two cases brought forward as examples, of course they were deemed conclusive, but he must say that he did not see sufficient evidence to warrant them in drawing the conclusion that they were true cases of typhus. At the same time he thought the profession was very much indebted to Dr. Dundas for the able manner in which he had brought the subject forward, and the zeal which he had manifested. (Applause.)

Dr. DUNDAS would refer Dr. Dickinson to Mr. Edney, now present, who had the treatment of the cases. There were always some 100 cases in the Fever Hospital. These two cases did not happen to have eruptions, but he had seen hundreds of cases with eruptions.

Mr. CROMPTON thought it was for Dr. Dickinson to state what these two cases were, if they were not fever.

Dr. DUNDAS merely brought forward these two cases because they happened to be the last, but there was Mr. Eddowes present who had treated many hundred cases in the Fever Hospital.

Dr. NOTTINGHAM said they were all perfectly satisfied of Dr. Dundas's great experience with regard to typhus fever, but would he be kind enough to give them a few cases treated simply on the plan alluded to, without the addition of any other agent.

Dr. DUNDAS quoted cases which had been treated successfully with quinine only, by Dr. A. B. Steele, Medical Superintendent of Irish Quarantine and Fever Ships in the Mersey, with the following summary of Dr. Steele's experience:—

"In the first case, the decided effect on the objective symptoms of the disease, in *twenty-four hours*, was so striking as at once to convince me of the value and importance of the remedy; and this improved condition was produced without the collateral advantages of *ventilation, cleanliness, nursing, nutritious diet, or stimulants*,—a fact which greatly enhances the value of this mode of treatment, in the hands of those who, unhappily, have to contend with the disease under the most unfavourable circumstances.

"I have witnessed the results of various methods of treating fever, in several hundreds of cases, during the epidemic of 1847, in our Fever Hospital, and on board the Fever Ships in the Mersey, and subsequently in the town; but I have never found any remedy, or remedies which appeared to me to cut short the disease, or modify the symptoms, in the same decided manner in which the quinine has done when fairly tried."

Mr. CROMPTON expressed it as his opinion that it would be better to use the term *quinism*, or *quininism*, instead of the term "cinchonism."

Dr. DICKINSON wished to say that he did not desire to cast any imputation whatever upon Dr. Dundas's mode of treatment.

The PRESIDENT asked,—Were all the cases of fever treated with quinine now?

Mr. EDDOWES said that only the worst cases were treated by that method, on account of the expense.

Dr. PETRIE thought Dr. Dickinson's observations merely referred to the two cases cited, the history of which appeared deficient.

The PRESIDENT asked whether there were any cases in the hospital at that time under this mode of treatment.

Mr. EDDOWES said there were, daily.

Dr. DUNDAS read over the symptoms in the two cases again.

Dr. DICKINSON still thought they were not conclusive.

Dr. NOTTINGHAM said, perhaps it would save time if Dr. Dickinson would state what he considered symptomatic of typhus fever.

Dr. DICKINSON said there were many cases having the symptoms named.

Dr. LYON said he believed he attended in the unfortunate position of a visitor that day, but, with their permission, he wished to ask a question. He was struck by the statement of Dr. Dundas as to the great number of fever cases in Liverpool. It seemed to him

that that was an enormous ratio of fever at this time of the year. He believed the number of cases in Liverpool did not exceed the number in Manchester. The influx of Irish caused a preponderance of fever.

Mr. EDDOWES said there were 100 cases in the Liverpool Fever Hospital.

Dr. LYON said that in Manchester there were thirty-three or thirty-four cases in the fever-ward at the present time, but that did not include the great body of fever patients which it formerly did, as they had separate establishments in each of the unions of the town. In Manchester, therefore, the number of fever patients collected together in one point had diminished.

Dr. DUNDAS gave the following cases of Mr. Gildersleeves', the Union Medical Officer of Liverpool:—

Extract of a Letter from T. B. Gildersleeves, Esq., Union Medical Officer, of Liverpool.

"51, Great George Street, 23rd of March, 1852.

" Hugh Evans resisted the effects of quinine for some days; he took altogether sixteen doses of ten grains, and the only effect for some time was increased drowsiness. It was not until the last day, when I ventured on six consecutive doses of ten grains, that a favourable change occurred."

Cases 1 and 2 by Mr. Gildersleeves.—"Caroline Moore, aged 35, and Barbara Moore, aged 14, mother and daughter, living in a wretched court, No. 4, Jamaica Street, were both attacked with fever, and lying in the same bed. The mother had been ill seven, the daughter five days. Symptoms of typhus were well marked; the tongue was coated with brown fur and quite dry; sordes were present on the teeth; the skin was hot, dry, and covered with petechial spots; the pulse upwards of 100; the eyes were suffused; there was prostration; in the mother some delirium. They had taken salts and senna of their own accord before I visited them. They refused to go to the Fever Hospital. I ordered for the mother ten grains, and for the daughter five grains of quinine every three hours.

"After the second dose the mother became quite deaf; the daughter, after the third dose, complained of tingling in her ears. The medicine was discontinued with both, and sleep for some hours, followed.

"On the following morning both were quite convalescent. The countenance was cheerful; the tongue moist and the brown fur had disappeared. The petechial spots remained for more than a week, and great debility, but there was no relapse."

Case 3.—"Hugh Evans, No. 3, Crump Street, had been ill two days. I prescribed a dose of calomel and antimony, under the supposition that the disease was simple febricula. Typhoid symptoms supervened on the fourth day. The tongue was brown, with sordes on the teeth; pulse 110. He had severe headache, and low muttering delirium. I ordered three ten-grain doses of quinine, one to be taken every three hours, and six ounces of wine to be taken at intervals; a blister to the nape of the neck.

"Fifth day.—There was no improvement; the quinine and wine were continued as yesterday.

"Sixth day.—There was slight improvement; less stupor. The quinine and wine were continued.

"Seventh day.—The patient was in all respects worse; he was covered with petechial spots; greatly prostrated; and had subsultus and twitching of the limbs. I ordered six ten-grain doses of quinine, one to be taken every three hours; his wine to be continued, and a quart of ale to be given.

"Eighth day.—There was a most remarkable change. The tongue was moist and clean; the brown fur gone. He was perfectly sensible; complained of great debility, but as regarded fever, was quite convalescent. He had no relapse.

T. B. GILDERSLEEVES."

Dr. LYON said that the cases brought forward by Dr. Dundas forcibly recalled to his mind the disadvantages against which they formerly had to contend in cases of typhus. The patients were frequently confined in dirty close habitations, with the absence of anything like pure air. They then used to "throw in" bark and wine, a practice which had become obsolete for a great length of time. Dr. Lyon proceeded to say that fever required different treatment according to peculiar situations and circumstances; but pure air effected more than medicine did formerly.

Mr. TURNER remarked that although there were cases in which the same symptoms did not present themselves as in pure typhus fever; still the symptoms being similar the same remedies were applicable. In one class of cases there was infection, and in the other there was not. In cases like those of the Irish, who some short time ago immigrated into Liverpool and Manchester in such hordes, and in a state of the greatest depression bordering on starvation, quinine must be very beneficial. But the question was respecting those in the Liverpool Fever Hospital. He thought Dr. Dundas was not prepared to say that all the cases admitted into the Liverpool Fever Hospital were cases of fever. Now, there were cases in the Manchester Hospital which were not fever, but cases suspected of being likely to terminate in typhus, and which were admitted in order to preserve the district in which they originated. They could not distinguish fever in a very early stage. Did they admit small pox into the Fever Hospital?

Mr. EDDOWES said they had small-pox wards in Liverpool.

Mr. CROMPTON had great pleasure in moving a vote of thanks to Dr. Dundas. He had attended many meetings of this Branch and of the general Association, but he did not remember having listened to a paper of greater interest than that they had just heard. In what he said he by no means wished to commit himself to Dr. Dundas's views, though he thought that quinine might be used with great advantage. It appeared to him that this was one of those questions which the Association, as a body, ought to take up; that the members ought to try the plan, and communicate to Dr. Dundas the result of their experiments. (Applause.)

Mr. BURROWS seconded the vote of thanks to Dr. Dundas, which was carried by acclamation.

Quackery.

Mr. ELLIS JONES alluded to the subject of quackery, and said that in Edinburgh they had a summary mode of dealing with impostors. He read the following extract from a letter bearing upon this subject:—"I believe the Doctor is in custody on account of several cases of pretended cures, or at all events, of patients treated and charged as a medical practitioner. It is not yet known which nor how many of them may be ultimately proceeded upon. The plea for the Crown will be that he knew he was not a "M.D.," and that by representing himself to be so, and receiving money which was paid on the faith of that representation, he has committed the offence which our law calls "Falsehood, Fraud, and Wilful Imposition." "The Baron" got his ten years from *Edinburgh*, and it is not at all unlikely that the "Doctor," will be just as severely dealt with. He was liable to ten years imprisonment. The man referred to practised in Liverpool some time since, and his name was Murray *alias* Watson.

Dr. NOTTINGHAM then read a paper "On the Treatment of Conical Cornea," for which he received the thanks of the meeting.

THE DINNER.

At three o'clock the members dined together at the Adelphi, where the attendance was rather more numerous than at the business meeting. The provision made by Mr. Radley was very creditable to his establishment, and calculated to enhance his reputation in matters of the *cuisine*. R. Bickersteth, Esq., presided; and amongst those present were George Southam, Esq., Manchester; James Petrie, M.D., Liverpool; A. O. Leete, Esq., Newton Le Willows; P. Macintyre, M.D., Liverpool; George Daglish, Esq., Wigan; Edmund Lyon, M.D., Manchester; John Nottingham, M.D., Liverpool; J. Armitage Pearson, Esq., Liverpool; Thos. Turner, Esq., Manchester; John Hatton, Esq., (Honorary Secretary,) Manchester; Ellis Jones, Esq., Liverpool; John Halliday, Esq., Seacombe; James Hakes, Esq., Liverpool; Edw. Waters, M.D., Chester; Thomas Gaskell, Esq., St. Helen's; Wm. Wall, Esq., Northern Hospital, Liverpool; J. Sharp, Esq., Warrington; Henry Pritchard, Esq., Fairfield; W. H. Fitzpatrick, Esq., Knotty Ash; Edmund Park, Esq., West Derby; Joseph Dickinson, M.D., Liverpool; Edward Batty, Esq., Liverpool; J. Black, M.D., Bolton; George Malett, Esq., Bolton; Robert Dundas, M.D., Liverpool; A. D. Dunstan, Esq., Holmes Chapel; W. H. Duncan, M.D., Liverpool; and S. Crompton, Esq., Manchester. Several excellent speeches were delivered, and the greatest harmony and festivity prevailed.

The PRESIDENT having given the usual loyal toasts, which were drunk with enthusiasm, proposed, "The Provincial Medical and Surgical Association, and Sir Charles Hastings." (Drunk with applause.)

Dr. DICKINSON regretted that it had not fallen to the lot of some one more able to respond to this toast. In

eloquent language he alluded to their early struggles, the anxieties and fears of the medical man, which were, however, amply repaid by the smiles of royalty, and the encouraging approval of the first seats of learning. (Applause.) When they saw Sir Charles Hastings in the position which he now occupied, looked upon as he was, unequalled in his profession, they could not but feel satisfaction and pride. (Applause.) In conclusion Dr. Dickinson said, that no class of men derived greater benefit from social meetings of this description than those belonging to the medical profession, and he hoped that such reunions would more frequently take place, to cement them in the bond of brotherhood and good feeling. (Applause.)

The PRESIDENT next gave, "The Lancashire and Cheshire Branch of the Provincial Medical and Surgical Association."

Mr. ELLIS JONES briefly responded. He expressed the satisfaction which the medical men of Liverpool felt at seeing so many gentlemen from other places present. He should have liked to have seen more of them at their meeting at the Medical Institution; and he hoped that, (although everything had passed off exceedingly well,) next year, whether they met at Chester or elsewhere, they would have a larger muster. (Applause.)

The PRESIDENT gave, "The late President and Vice-Presidents, Thomas Turner, Esq., R. Broadbent, Esq., and Dr. Broughton."

Mr. THOMAS TURNER said, that having had the pleasure of presiding over a meeting held in Manchester some months ago, he could not forbear the pleasure of attending this meeting, and congratulating Mr. Bickersteth on the position to which he was called, (Applause.) He agreed with Dr. Dickinson, that these meetings were not only most delightful, but profitable in a professional point of view, and not only in relation to themselves, but the community at large, (Applause.) For it could not be considered that these meetings were private. There was some one amongst them who, no doubt, would give their proceedings publicity; and they knew that the public were curious to know what was going on in the profession. It was true they were assailed by unworthy intruders,—by men who had deviated from the path of honour, and chosen that of disgrace. They would all agree with him when he stated that there were two roads in the profession: one which the disappointed and ignorant, and men who did not possess moral principle, too often pursued; but he was happy to say there was a straight path, which was bounded on each side by those principles of uprightness which ought to attach to their profession, and without which they were not worthy of standing in society. (Applause.) Their profession had certain principles connected with it—dignity, honour, liberality, humanity, and unwearied searching after truth. (Applause.) He believed these were the principles by which they should be guided, and that if they were departed from in any one instance, the individual so deviating committed a great breach of integrity, and was undeserving of esteem, and of any notice other than the ignominy which would attach to him. What was it which gave their profession

the position which it now held in the minds of all men who appreciated what was right? Their profession was characterised as a dignified profession. There was no dignity in the profession itself, but it depended upon the conduct of those who belonged to it. (Hear, hear.) He would not call men by their names according to the doctrines they professed, but he said if they saw men departing from those principles of liberality by which they should be actuated, they must be looked upon as unworthy. When they saw men condemning their brethren, either by innuendo or in some other way, and making it appear as though they were in error, and were guilty of some want of talent, skill, or integrity, such men were not worthy to be included in the list of the honourable members of the profession. (Applause.) It was only the dishonourable who were excluded from a room like that; they met men whom they had a pleasure in meeting, whom they recognized as honourable members of the profession, and with whom they could associate without reproach. (Applause.) Mr. Turner, in conclusion, proposed "The health of their President, Mr. Bickersteth." No man in the profession stood higher in public estimation, and in private worth, than the gentleman who occupied the chair, and if he was not proud of his own position, he ought to be proud of the associates he had in his excellent brothers. (Applause.) How much law, divinity, and physic had been dignified by the name of Bickersteth. (Applause.) He was sure he only feebly expressed the sentiment of the meeting when he wished Mr. Bickersteth and his family long life, and might they, as long as they lived, continue an ornament to society.

The PRESIDENT, in reply, said that Mr. Turner had placed him in considerable difficulty. He had been too hard a worker for between forty and fifty years to be a good speaker. (Applause.) He had no power of making long speeches, but he returned them his sincere and hearty thanks, and he hoped that a few more years would be spared him, though his race was nearly run, to meet them on these occasions. (Applause.)

Dr. DUNCAN proposed "The health of the President-Elect, Dr. Black," a gentleman whose personal acquaintance he had had the pleasure of enjoying for many years, and whose name was known to them all by his writings. (Applause.)

Dr. BLACK said the compliment was quite unexpected, and therefore anything he could say in return must be altogether inadequate. He had long been a member of this Association, and at this distant period he was happy to meet the Branch in Liverpool. (Applause.) They had not mustered so strong as he expected. He had seen a larger meeting at Newton, and whether the comparative smallness of their attendance was owing to their getting at one end of the pole or not, he could not tell. Certain it was that the centre attracted both ends; however, he was much pleased with their proceedings that day, and with the sentiments expressed. (Applause.) A great change was going on, and great innovation was being made in what was called the scientific practice of the profession, both by quacks and regular practitioners. Their great object should

be, to guard against empiricism, which in many instances had taken the place of pure science. They knew by discoveries under the microscope that the science of chemistry was one of profound research. (Hear, hear.) Those who had adopted the profession of empiricism pretended that they could cure disease, without reference to anatomical or pathological science. According to their doctrine a certain number of *grains* would cure, without reference to either. (Applause.) Chemistry was the most exact science in the world, but their pursuit was by no means confined to that, and he warned them against delivering themselves up to a sort of theoretical empiricism, mesmerism, homœopathy, or whatever else it might be. The great thing they had to guard against was, losing sight of their old foundations. (Great applause.)

Mr. MALETT proposed the "Council of the Branch."

Mr. SOUTHAM responded. He did not know that the duties of the Council were very arduous, but he believed they had some few to perform, and he was glad to see that their services were appreciated. (Applause.) They were very much indebted to Sir Charles Hastings for the present prosperity of the Association, but the prosperous state of this Branch was mainly owing to the ability and energy displayed by their Hon. Secretary. (Applause.) So long as they retained Mr. Hatton in office, they would continue to prosper, and he thought it would be very advantageous if they had a gentleman in Liverpool to take a similar active part to that taken by Mr. Hatton in Manchester. (Applause.)

The PRESIDENT said that, after the observations they had just heard from Mr. Southam, it was unnecessary for him to do more than simply propose "Mr. Hatton's health." (Applause.)

Mr. TURNER begged leave to say a few words. Mr. Hatton had signified his intention to resign, but on the solicitation of Sir Charles Hastings and himself, he had consented to retain the office of Secretary, and they would not part with him. (Applause.)

Mr. HATTON briefly acknowledged the compliment which had been paid him. It was a source of great gratification to him to be received in the way he always was at these anniversary meetings. Perhaps the President was not aware that he had now completed his tenth year of office. (Applause.) It was his wish now, as Mr. Turner had stated, to resign the Secretaryship into the hands of some other individual, as he did not think that any one was justified in holding office for such a length of time. Certainly his post was attended with a great deal of trouble, but then it had been to him a "labour of love," for he had seen his exertions on behalf of this Branch seconded by all the respectable members of the profession, and that amply repaid him. (Hear, hear.) Mr. Malett had said that he could not speak as to the arduous duties of the Council, but he (Mr. Hatton) could inform them that they were all concentrated on the Secretary. (Laughter and applause.) It was fully his intention to have resigned, but after the handsome manner in which he had been solicited to remain in office by Sir Charles Hastings, Mr. Sheppard, and Mr. Turner, he did not

think he should be justified in doing so. (Applause.) Meetings like this were their only means of keeping up the Association in an efficient state; he had now completed his tenth year, and if he could only get his professional brethren to join him at such meetings, he had no objection to be Secretary ten years more. (Applause.) They could not attend a meeting like that without being benefitted. They met old friends they had not seen for years, fellow students, and men whose acquaintance they wished to continue. Dr. Black had alluded to their more numerous attendance at Newton, but their meetings there had dwindled down to fifteen. At this meeting there were some thirty, and he hoped they would have double the number at Chester, and 120 the year following. (Applause.) When he looked at the railway map he found there was no place so well situated as South Lancashire and Cheshire for obtaining a good meeting of the medical profession. They were so centralized by the railways that they might, with a little exertion, obtain one of the largest branches in the kingdom. Mr. Hatton stated his belief that this was the first Branch which paid its own expenses. By the additional subscription of half a crown, which every one paid willingly, they were independent of aid from the Parent Society, and were enabled that day to make a donation of £5 to the Benevolent Fund. (Applause.)

Several other toasts followed. Mr. PEARSON proposed "The New Members," which was responded to by Dr. DUNDAS, who till that day had only been a member of the General Association. The PRESIDENT gave "The Visitors;" replied to by Dr. LYON. Dr. BLACK proposed "The memory of Dr. Jefferys;" Mr. TURNER, "Mr. Batty and Medical Education." Mr. BATTY acknowledged the compliment in an appropriate speech. The SECRETARY proposed "The Profession in Chester, and Dr. Waters," which was responded to by that gentleman. Mr. PEARSON proposed "The Maintenance and Honour of our Profession, and unity and good will to all legitimate Practitioners." (Applause.) He also proposed "Mr. Turner's" health, which was drunk with enthusiasm, and duly responded to. The health of "Mr. Ellis Jones (Local Secretary) and Mr. Pearson," who had made such excellent arrangements for the dinner, was proposed by the SECRETARY, and rapturously drunk. Mr. DUNSTAN proposed "Success to the next Meeting at Oxford," and the party broke up, having again drunk the health of their President, who in one brief sentence appropriately replied.

SOUTH-EASTERN BRANCH.

In consequence of the general meeting of the whole of the Parent Association having been appointed to be held in 1851, at Brighton, it was considered by the members of the committees of management of the last and present year, to be unnecessary and inexpedient to have the usual annual meeting of this branch.

It was therefore agreed that the Folkestone meeting, as appointed at Guildford, should be postponed to Wednesday, the 30th of June, 1852, to which the members of the South-Eastern Branch were invited.

The gentlemen assembled at the Pavilion Hotel, when there were present—Fred. Harvey Sankey, Esq., Wingham; Amelius Sicard, Esq., Bridge, Canterbury; James Reid, Esq., Canterbury; John Beet, Esq., Ashford; Peter John Martin, Esq., Pulborough; Edward Long, Esq., Barham; Thomas Martin, Esq., Reigate; George Bottomley, Esq., Croydon; Peter Martin, Esq., Reigate; Isaac Hargraves, Esq., Tunbridge Wells; William Alexander Greenhill, M.D., Hastings; John Penkivil, Esq., Staplehurst; Alfred B. Andrews, Esq., Canterbury; John T. Terry, Esq., Wittersham; Robert Martin, M.B., Pulborough; Andrew Wood Baird, M.D., Dover; William Sankey, Esq., Dover; Francis William Pittock, Esq., Sellenge; Henry Whitfield, Esq., Ashford; Thomas H. Silvester, M.D., Clapham; Silvester Eastes, Esq., Folkestone; Peter Rascow, Esq., Folkestone; James Stedman, Esq., Folkestone.

At twelve o'clock, the President, Mr. Stedman, took the chair. The minutes of the proceedings at the meetings at Guildford and Reigate having been approved and confirmed,

Mr. STEDMAN, of Guildford, then addressed the gentlemen present to the following effect:—

Gentlemen,—After an interval of two years, occasioned by the holding of the general meeting of the Association at Brighton last year, within this district, I have to express the great gratification I feel in common with many of my friends in Surrey and Sussex, at being enabled to meet you at this interesting place—interesting in many points of view, and more especially so, as being the birth-place of one of the greatest of physiologists and physicians, who will I am sure, be alluded to by my successor in this chair, in a much more able manner than I can have the power of doing. Permit me to offer my best thanks for the great kindness and condescension I have experienced from the members of the South-Eastern Branch of the Association, during the time I have had the honour of holding the presidency of this branch, and more particularly for the honour I received by having so numerous an attendance of the members at our meeting at Guildford. At that meeting the nomination of Dr. Soulbey of Dover, as the future President, was hailed with great satisfaction. In deploing his absence, I am sure that I express the great regret and sympathy of the general Association, and of this branch in particular, at the cause of his being unable to meet us on this occasion. I have just now received a letter from him, which I shall presently take the liberty of submitting to you, and I trust that he may be assured from this meeting, that it will be a source of joy to us all when we hear of his being restored to health, so that he may be enabled to pursue his course of usefulness. It now becomes my pleasing duty to place in this chair a gentlemen whose general reputation and high standing in the profession entitle him to receive our best support, and who, on the emergency of Dr.

Soulby's illness, has kindly undertaken to preside on this occasion, and in the fulfilment of the duties of the President of this meeting, he will prove that he is eminently qualified to dignify the Association.

The SECRETARY then read the letter, which had been addressed to Mr. Stedman by Dr. Soulbey, expressing his deep regret that he was unable to attend the meeting as the successor of Mr. Stedman, as had been appointed at the meeting at Guildford, on account of severe illness, whereupon it was moved and seconded unanimously,—

“That this meeting desires to express to Dr. Soulbey the sincere regret of the members present at the illness under which he is now suffering, and which deprives the meeting of the advantages of his presidency, and to offer to him the expression of their sympathy and cordial good wishes for his complete recovery.”

The Treasurer then presented his summary of account from the 26th of June, 1850, to the 30th of June, 1852, as follows:—

Expenditure.

	£	s.	d.
1850.			
June 26th.—Balance due to the Treasurer	3	13	4
Oct. 21st.—Account paid to Mr. Allingham—Printing, stationary, and stamps	14	16	2
1851.			
August 25th.—A further account—Printing and stationary expenses	2	11	6
Sept. 11.—Printing account	0	12	6
1852.			
June 24th.—Printing, envelopes, stamps	3	0	6
„ 30th.—Balance in the Treasurer's hands	4	12	0
	£29	6	0

Receipts.

	£	s.	d.
1852.			
June 30th.—Amount received in half-crown subscriptions	29	6	0

Examined and approved,

W. A. GREENHILL, M.D.
J. HARGRAVES.

Mr. Stedman having then left the chair, it was taken by Mr. SANKEY, of Wingham, who addressed the meeting as follows:—

Gentlemen,—Dr. Soulbey, the President-Elect, has requested me to take his place on the present occasion, a task I can assure you I should have shrunk from had I not felt that I should have the able assistance of our most excellent Secretary in directing me to a proper fulfilment of the duties which will devolve upon me; I must, however, beg your indulgence and support, and as I have had the pleasure of attending so few of your meetings, I trust that any deficiencies on my part will be excused.

Dr. Soulbey, I regret to say, is prevented by severe illness from joining us. I am sure that those among you who know the untiring energy, the zeal, and the *esprit de corps* which he has always shown, will readily believe that no trifling matter would have deprived us of his services this day; and I hope that I may be

allowed, when I again see him, to convey to him the sympathy of all here present. I trust also that you will all join me in expressing our cordial thanks to Mr. Stedman, the retiring President, for the kindness and ability evinced during the two years he has occupied the chair; those among you who had the pleasure of assembling under his able presidency at Guildford, can better appreciate his services than I who had not the opportunity of being present on that occasion. Amongst those who were then present, there was one (Dr. Mackness,) who has since passed "to that bourne from whence no traveller returns," and whose death was so feelingly alluded to in Dr. Jenks's address last year at Brighton, especially in reference to the medical topography of the southern coast, on which he was then to have addressed us, had he been spared.

The town of Folkestone in which we are now assembled, is one of considerable antiquity. Lambarde says it was called in Saxon, "*Folcestone, id est populi lapis*, or else Flostane, which signifieth a rocke, coast, or place of stone which beginneth here, for otherwise the cliffe from Dover till you come almost hither is of chalke." It is only of late years that it has been resorted to by invalids. The neighbouring town of Sandgate has, however, for thirty or forty years been known as a favourite bathing place, especially by families connected with the county. The introduction of the railway has had considerable influence on both places, as the population returns will show. In 1841 the population of Folkestone, in which the greater part of Sandgate is included, was 4418, at the last census it amounted to 6637, an increase of 50 per cent.

The situation of Folkestone is very inviting, the recession of the Chalk Hills, which here leave the coast, forming an amphitheatre, sloping to the south, and protected by the heights above from the north and east. From the base of the hills several springs burst forth, which, meandering towards the sea, increase the verdure, and add to the variety of the scene. Of these springs, one at Ford is chalybeate, and if it is not so powerful as some more celebrated, may, nevertheless, when combined with the advantages of sea-air and bathing, be of essential use in certain cases. According to the local guide book the water contains carbonate, muriate, and sulphate of soda, carbonate and muriate of lime, and carbonate of iron.

Mr. Mottley, who has examined the vital statistics of several places on the coast, with the view of comparing them with Margate, classes Folkestone among the healthiest, the deaths being as follows:—

At Margate	1 death to 63 living.
„ Folkestone	1 „ 63 „
„ Hastings	1 „ 52 „
„ Tunbridge Wells ...	1 „ 49 „
„ Dover	1 „ 47 „
„ Brighton	1 „ 47 „

Both Folkestone and Sandgate are well supplied with every accommodation for visitors seeking either health or amusement. The excellent bathing at the latter place, the beautiful walks and drives in the neighbourhood, with the great variety of the geological and botanical features of the surrounding locality, and the facility with which either town can be now reached by railway, must continue to render them places of favourite

resort. Folkestone has been long noted for the excellence of its fish; possibly its bloater herrings may be in as much repute in modern Rome as were its oysters in ancient days.

Lambarde tells us,—“John Twyne commendeth above all others, the oistres that come from Folkestone, as well for the taste as for the greatness, contending that the same were those that for dainties were anciently transported to Rome.”

There are not many names of note connected with Folkestone, passing over that of John Philipot, the author of "*Villare Caulcanum*," or Kent, surveyed and illustrated, who was a native of this place.

The most illustrious name is that of William Harvey, the immortal discoverer of the circulation of the blood; and as our meeting was appointed to be held at Folkestone, with especial reference to it as his birth-place, I purpose, with your permission, to give a short sketch of his life. He was born in this town on the 2nd of April, 1578, the oldest of seven sons of Thomas Harvey and Joan Halke. William adopted the profession of medicine; his five brothers, Thomas, Daniel, Elial, Michael, and Matthew, became merchants, trading with the Levant. Another brother, John, was a man of note in his day, being one of the King's receivers for Lincolnshire; and sat as a Member of Parliament for Hythe in the 16th year of Charles I. At the age of 10 years Harvey was sent to the grammar school at Canterbury, and at 16 was removed to Caius College, Cambridge. He remained there three or four years, and at the age of 19 took the degree of B.A., in the year 1597. In the following year he commenced the study of anatomy, at Padua, under the celebrated Fabricius ab Aquapendente. Having passed five years at that, then celebrated University, he, in the 24th year of his age, 1602, obtained his diploma as Doctor of Medicine; and returning to England in the course of the same year, and submitting to the requisite forms, he also received his Doctor's degree from his original University of Cambridge; and then going to London, and taking to himself as a wife the daughter of Dr. Lancet Browne, in his 26th year, he entered upon the practice of his profession. In 1604 Harvey's name appeared on the roll of the candidates for admission to the fellowship of the College of Physicians; and at the expiration of the probationary three years he was admitted to the distinction to which he aspired. In 1609 he was elected to the office of Physician to St. Bartholomew's Hospital. In 1615 he was chosen to deliver the lectures on anatomy and surgery at the College of Physicians, founded by Dr. Richard Caldwell; and it is generally allowed that in the very first course he gave, in the month of April following, he presented a detailed exposition of those views concerning the circulation of the blood which has rendered his name immortal. The circulation, it would seem, continued to form one of the subjects in the lectures on anatomy which Harvey continued to deliver for many years afterwards at the College of Physicians; but it was not till 1628, in the 50th year of his age, that he published his "*Exercitatio Anatomica de motu Cordis et Sanguinis*." He had previously been appointed Physician Extraordinary to the reigning Sovereign, James I., and continued to hold the

appointment in the reign of his successor Charles I., who appears to have taken great interest in the physiological enquiries of the great anatomist, and to have had several exhibitions prepared of the punctum saliens in the embryo chick and the deer, and to have witnessed the dissections of many of the does which he liberally placed at Harvey's disposal whilst he was prosecuting his inquiries into the subject of generation. Harvey, as a physician, was now in the zenith of his reputation. His practice, if we may judge by the sum of money he is stated to have left behind him, must have been very considerable; but his connection with the Court stood in the way of his improving his position; and then, the appearance of his work on the circulation gave a decided check to his professional prosperity, which he himself ascribed to the opposition and jealousy of his rivals; but it is more probable that the habits of abstract speculation in which he then began to indulge caused him to neglect the usual arts of gaining the confidence of the public. There may be some foundation for the popular notion that he who is an ardent cultivator of any collateral science, or even of any one branch of the elements of medical science, is seldom a good practical physician or surgeon. Patronage and fashion may and do push people into notice who, if left to themselves, would never have been heard of; but I question whether the "jealousy of rivals" could or can obstruct the progress of genuine talent, accompanied with undeviating rectitude of conduct. Harvey, however, had the happiness in his lifetime to find the clamours of ignorance, envy, and prejudice against his discoveries totally silenced, and to find them universally established. Harvey was not only an excellent physician, but an excellent man. His modesty, candour, and piety were equal to his knowledge. The farther he penetrated into the wonders of nature, the more was he inclined to venerate the author of it. His religious sentiments appear to have been active. The exordium to his will is unusually solemn:—"In the name of the Almighty and Eternal God, amen! I, William Harvey, Doctor of Physic, do by these presents make and ordain this my last will and testament. Imprimis, I do most humbly render my soul to him that gave it, and to my blessed Lord and Saviour, Jesus Christ, and my body to the earth," &c. He evinces also true and elevated piety throughout the whole course of his work on generation. His generosity is shown in the noble gift during his life of his property to the College of Physicians. Nor was he unmindful of those social qualifications which conduce so much to the harmony of the profession. Among other directions which accompanied the gift he directs that "To maintain friendship there shall be at every meeting once a month a small collation, as the President shall think fit, for the entertainment of such as come; and once every year a general feast for all the Fellows; and on the day of such feast shall be an oration in commemoration of the benefactors by name, and what in particular they have done for the benefit of the College, with an exhortation to others to imitate, and to the members to study and to search out the secrets of nature by way of experiment; and, for the honour of the profession, to continue mutually in love."

In person, Aubrey informs us, Harvey was not tall, but of the lowest stature, round faced, his hair black as a raven, olive complexioned, little round black eye, full of spirit. His temper was said to be choleric; but he seems, nevertheless, to have had it at all times under his control.

Harvey's second great work, "*Exercitationes de Generatione Animalium*," must have cost him great labour, and was not published till 1651, when he was upwards of seventy years of age. He has not left on record any account that I can find of his treatment of disease, excepting in his own case; being subject to attacks of gout he treated himself on the hydropathic plan. Aubrey tells us "that he would then sit with his legs bare, though it were frost, on the leads of Cochraine House, put them into a pale of water till he was almost dead with cold, and betake himself to his stove, and so 'twas gone."

Harvey appears to have preserved his faculties unimpaired to the last, and died on the 3rd of June, 1657, in the 80th year of his age, and was buried at Hampstead, in Essex, in which county, at Chigwell, the descendants of one of his brothers resided, till they became extinct in the male line, in 1830.

A portrait of Harvey, by Cornelius Jansen, is in the library of the College of Physicians. There is also a very excellent portrait of him at the Canterbury Hospital, supposed on very good authority to have been likewise painted by Cornelius Jansen, who painted several portraits at Bridge, near Canterbury, about the same time. There are also good copies in private collections, as also one at Caius College.

The Folkestone Harveian Literary Institution was founded in 1845, but it has no special reference to the medical profession. The name Harveian was adopted as being likely to give credit and reputation to the Society.

Mr. Mackie, a gentleman of Folkestone, has a collection of geological specimens and fossils of the neighbourhood, which he will be happy to offer to the inspection of gentlemen attending the meeting.

Gentlemen,—I have not ventured to say anything on the unsettled subject of medical politics, leaving that to those who are more competent to the task. There is one subject, however, on which I am happy to think more unanimity prevails, although there are rival schemes of medical benevolence. Our worthy associate, Mr. Newnham, I have no doubt, with his usual ability and perseverance, advocate the claims of the Benevolent Fund connected with this Association. There is another project, "The Medical Benevolent College," which has already received such extensive patronage from the profession and the public, that I cannot doubt but that the benevolent intentions of its projector, Mr. Probert, will be fully carried out, and that we shall shortly see such a building raised as may be worthy of so holy a cause. There are also several local benevolent societies, and among them one connected with this county, which has been established upwards of sixty years, and has in that time distributed more than £10,000 amongst its decayed members, their widows and orphans. It still continues a steady course of usefulness, and is worthy of the support of all who reside within its limits.

In conclusion, gentlemen, I have to thank you most

cordially for the kindness and attention with which you have listened to my address. I should not have consented to occupy the honourable position in which I have this day been placed, had I not felt, as I said at the commencement, that I should have the kind assistance of Mr. Martin. I trust that I may have many like opportunities of meeting my professional brethren, for no one I can assure you feels more than I do the truth of the words of Harvey that I have just quoted, "*that these meetings tend to the honour of the profession, and cause us to continue mutually in love.*"

SHROPSHIRE BRANCH.

THE Annual Meeting of the SHROPSHIRE BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, was held at the Boreatton Arms Hotel, Baschurch, on Thursday, the 8th July. There were present—Joseph Hickman, Esq., President; Robert Broughton, Esq., Vice-President; Dr. Johnson, Dr. H. Williams, P. Cartwright, Esq., J. Y. Arrowsmith, Esq., Wm. James Clement, Esq., Richard Thursfield, Esq., J. N. Heathcote, Esq., Samuel Wood, Esq., James Bratton, Esq., J. P. Wilding, Esq., John Rider, Esq., J. R. Humphreys, Esq.

The general business of the Association was gone into at length, and the following resolutions were unanimously agreed to:—

Proposed by Dr. JOHNSON and seconded by S. Wood, Esq.,—"That this Branch entirely approves of the Draft Medical Bill, and recommends most earnestly the Parent Association to adopt such measures at their next Meeting at Oxford, as shall best insure its introduction to the Legislature."

Proposed by W. J. CLEMENT, Esq., and seconded by RICHARD THURSFIELD, Esq.,—"That this Branch strongly deprecates any alteration in the editorship or publication of the *Provincial Medical and Surgical Journal*, and considers that the present Editors are deserving of the best thanks of the Association."

Robert Broughton, Esq., was chosen President for the ensuing year.

The members afterwards sat down to an excellent dinner when they were joined by several friends, and separated after enjoying a very pleasant evening.

Foreign Department.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

THERE has been a great dearth of interesting matter of late in the meetings of the French Medical Societies, and the discussions have, as a matter of course, been brief, as well as somewhat deficient in animation. The principal communications to the Academie de Medecine in point of value are these:—

1. "A Case of Sanguineous Tumour of the Head of the Fibula, Fatal after Operation, in which the Death was attributed to Chloroform."

2. "A Report on a Memoir by M. Mayer, respecting a New Instrument for Scarifying the Uterus."

3. "A Case of Reduction of an Inverted Uterus after Five Months."

4. "On Suicide in Connection with Diseases of the Generative Organs."

5. "On the Therapeutic Value of Manganese in Chlorotic Affections."

Of these we shall notice one or two more at length.

The "Case of Complete Inversion of the Uterus, Reduced at the Expiration of Five Months," is reported by M. Barrier, and occurred in a young woman aged 24, during her second labour. When seen by M. Barrier, she was unable to stand, complained of great pain and dragging from the loins, constipation, and dysuria. She had repeated hæmorrhages, which had reduced her to a stage of extreme anæmia. On examination a pyriform, soft and velvety tumour presented itself to the touch. The pedicle was round, high up in the vagina, and surrounded by a ring, which admitted the finger for a short distance. The tumour had the natural consistence of the uterus, and was neither preternaturally hard nor soft. The diagnosis was, that a complete inversion of the uterus existed. As no medicinal treatment had any controul over the hæmorrhage, M. Barrier determined to attempt the reduction of the inversion, which he accordingly did, previously placing the patient under chloroform, and in the lithotomy position. His endeavour was successful, and the reduction complete.

The beneficial action of *manganese as an adjuvant to iron* in the treatment of anæmia, has been further investigated by M. Petrequin. According to this author manganese and iron are therapeutical congeners, the former being, in many cases, an admirable substitute for the latter, and in others acting as a valuable auxiliary, fulfilling indications which the chalybeate had failed to accomplish. There are cases of chlorosis in which iron is absolutely ineffective, and there are others in which amendment takes place up to a certain point, and no further, the iron seeming to have lost the power of further reconstituting the blood. It is in such, according to M. Petrequin, that we may have recourse to manganese, with the greatest advantage, in combination with the chalybeate. The preparations he employs are usually in the form of pills, but the two metals may be combined in the form of syrups, mixture, or in chocolate.

ACADEMIE DES SCIENCES.

IN the Academie des Sciences some few physiological papers of interest have occupied the attention of the members; of these we mention only that by M. Colin, presenting some researches on the "Secretion of Saliva in the Solipeds." Of this paper the following is a summary:—

1. All the glands of the salivary system are active during mastication; nevertheless, each has a special activity, brought into play by certain influences.

2. The parotids do not secrete with equal abundance during a given period of time, but alternate in activity according to the side on which the food is masticated.

3. The secretion of the submaxillary gland is not subject to these alterations, but is equal throughout the process of mastication.

4. Of the whole amount of salivary secretion supplied, the parotids furnish two-thirds, the maxillary glands only a twentieth, the remainder is secreted by the sublingual and the buccal glands.

5. The salivary secretion seems in all cases to be excited by the direct stimulus of sapid substances; the "mouth watering" as an emotional phenomenon, is a fable.

6. The mere action of the jaws has no effect on the secretion of saliva.

On Puncture of the Abdomen in Tympanites.

A case in which tympanitic distension of the intestines complicated with obstruction, was beneficially treated by puncture, has been witnessed by M. Labric, who has made it the basis of a thesis, in which he has collated and commented upon all the instances of the kind which he could find on record.

In tympanites the gas may accumulate either in the intestines, which is the most usual site, or in the peritoneal cavity, which is a much more exceptional occurrence. The operation of tapping the intestines under these circumstances, is frequently performed in the lower animals, more particularly bullocks and sheep, in which, after a large repast upon green food, great gaseous distension of the stomach not unfrequently occurs. The veterinary surgeons perform the operation with a common trocar and cannula, and the relief is often immediate and permanent.

Much difference of opinion, however, exists as to the propriety of the operation in the human subject, peritonitis being dreaded as a likely result; but M. Lebric very justly objects to this apprehension, as uncalled for, as in nowise more likely to follow tapping for tympanites than for ascites, in which latter disease its occurrence is quite exceptional.

For the performance of puncture, the needle and the trocar have been respectively recommended; the author however, prefers the latter, taking care that it is of a small size, such as is used as a means of exploring doubtful tumours. The only precautions required is to choose the most prominent and sonorous spot, at which it is known that the bowels are closely in contact with the abdominal walls. The author relates his own case and three others. In all the relief was most marked and grateful to the patient; but as they were instances of insurmountable intestinal obstruction, in which the tympanitic distension was but one symptom, the ultimate result was of course fatal.

Treatment of Albugo by Galvanism.

Having seen in some journal that in Russia and Sweden albugo in the horse had been removed by the

aid of galvanism, M. Turck adopted the method in the human subject with the effect, he assures us, of greatly diminishing the opacity of the cornea. The case was that of a young girl, aged 13, who had been the subject of scrofulous keratitis, which left albugo of each cornea. That on the left side was not central, so that the child was able to see imperfectly; on the other eye it was so universal as to render her perfectly blind. She was considered incurable and had abandoned all treatment, when she came under the author's care for another affection, and he then determined to experiment with the galvanic battery.

He, accordingly, having set in action a battery of appropriate power, placed the zinc probe in the mouth, while with the copper or negative pole he lightly touched the cornea. The immediate effects were vertigo, nausea, and violent arterial pulsations, but these were soon subdued by a counter application of electricity to the lower extremities. The treatment was persevered in for forty days, with the result of considerably diminishing the opacity in both eyes, so that she was able to read with that eye which had been blind for more than ten years, while the other, though not cured, was so far benefitted that the patient was able to follow her occupation of sewing.

M. Turck farther says, that he has seen albugo in the horse removed in this way *in two minutes!*

On the Treatment of Facial Neuralgia.

M. Cazenave informs us (*Revue Medico-Chirurgicale*) that he has had marked success in removing the pains of hemicrania and facial neuralgia by means of the following pomade:—

Pure Chloroform, dr. iv.
Cyanide of Potassium, dr. iijss.
Axunge, oz. iij.
Wax sufficient to give consistence.

M. Cazenave professes to have tried the cyanide of potassium alone, without any benefit, and therefore concludes that it is this particular combination which is so valuable. The mode of using it is to rub ointment, the size of a pigeon's egg, into the scalp, and after which the head is to be covered with an oiled-silk cap. The inunction is to be repeated according to circumstances. In facial neuralgia it is rubbed in over the affected nerve.

On Free Cartilaginous Bodies in the Tunica Vaginalis.

M. Chaissaignac (*Revue Med. Chirurgicale*, Mai,) has made some observations on the pathology of the foreign bodies which are occasionally found floating free in the cavity of the tunica vaginalis. We say occasionally, for Sir A. Cooper, with all his extensive experience, never met with them in the living subject, deriving his information solely from inspection after death. The case reported by M. Chaissaignac is, therefore, of considerable value.

Case.—A man, aged 70, was the subject of double inguinal hernia. He had also hydrocele on the left side, which exhibited the peculiarity of containing a solid body, which could be moved freely in every

direction. He had never received a blow on the testicle. An incision being made, the foreign body, which, as was suspected, was quite free, was readily removed. In form it was ovoid, in colour white and shining. When divided it was seen to consist of two substances, a central yellowish matter, and a fibrous tissue, arranged in concentric laminae.

The author remarks, that although this peculiar body was perfectly unattached, the mark of a pedicle rendered it probable that it was once connected with the serous membrane, and that the pedicle had gradually become attenuated until it was entirely separated. He regarded this body as the exciting cause of the fluid contents of the hydrocele.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

On the Presence of a free Acid in the Lungs.

By M. VERDEIL.

This writer states that he has found in the parenchyma of the lungs of mammalia a distinct acid, which he has succeeded in obtaining in an isolated, perfectly pure, and crystallized condition. The tissue of the lung of an animal lately killed did not sensibly redden the blue turnsole paper. But when a mass of lung, cut up very fine, was macerated in warm water, it was found that the liquor possessed an acid reaction; which reaction became very manifest when the albumen and blood globules which coloured the liquid were coagulated.

This acidity is stated to be owing to a free acid in solution, in the juices with which the lungs are impregnated. This substance is formed of carbon, hydrogen, azote, and oxygen, in definite proportion. It crystallizes in brilliant needles, strongly reflecting the light. It is somewhat soluble in cold water, nearly insoluble in cold alcohol, but more soluble in boiling alcohol. Boiling absolute alcohol dissolves a very small quantity only. It is completely insoluble in ether. It possesses an acid reaction, and expels the carbonic acid from carbonate of potash and soda. When heated to 140 degrees, it does not lose water of crystallization; at a higher temperature it crepitates, becomes opaque, and is decomposed, giving rise to empyreumatic products; it forms a carbonaceous mass, which disappears completely, leaving no trace.

The parenchyma of the lungs, therefore, contains a free acid. The author has also been able to prove that a portion of the acid which he extracted from the lungs existed in the tissue as a salt of soda.

In reflecting upon the probable use of this acid he observes that, submitted to the general laws which govern chemical substances, it ought to decompose the alkaline carbonates carried by the blood; these, meeting in the lungs with the acid contained within the tissues, ought to form a new salt of soda, and carbonic acid should be set free.

The pulmonary vesicles constantly secrete this acid, which, coming in contact with the carbonate of soda

brought by the capillaries, the acid combines with the soda of the carbonate; the carbonic acid becomes free and passes off in respiration. The new salt of soda returns in the blood where it was found, not free, but combined with the soda. This research was continued; all the characters of the acid and the phenomena of respiration concur to verify, not a theory, but the fact, that an acid constantly secreted by the parietes of the pulmonary vesicles decomposes the carbonate of soda of the blood, and sets its carbonic acid free. This fact explains, amongst other physiological observations, the decomposition of the alkaline cyanurets and bicarbonates injected into the blood, when they arrive in the lungs, as M. Bernard has observed.—*Gazette Médicale de Paris*.

On the Molecular Origin of the Tissues.—By Dr. BENNETT.

Dr. Bennett read a memoir to the Physiological Society of Edinburgh, the object of which was to prove not only that cells were developed from nuclei, as had previously been ascertained, but likewise that these nuclei themselves originated in smaller bodies, viz,—molecules; and that these were the origin of the tissues. He also endeavoured to indicate the laws which governed their formation, arrangement, and subsequent development. The author showed, by a reference to the observations of Schleiden and Schwann, that the first step in the organization of all tissues was the coalescence of molecules and granules, into a cell-germ, which further derived a cell-wall from the agglomeration of other molecules. At any period in the progress of evolution the onward progress might be checked, when the structure became disintegrated in a manner inverse to its mode of formation. First the cell-wall became dissolved, then the nucleus, both of which were reduced to molecules, and then to an amorphous fluid. The author likewise mentioned another form of molecules, which he called secondary. These constitute peculiar secretions. The author next alluded to the origin and mode of formation, with the physiological and pathological importance of these three kinds of molecules, and described the investigations of Ascherson and Melsens. He concluded by pointing out the relation of a knowledge of this molecular formation to the study and treatment of disease. He stated, for instance, that in tubercular diseases the molecules of evolution were deficient, from absence of the fatty element in the chyle; and that in some other diseases, as in those of gouty, rheumatic, and scorbutic origin, a cure could only be effected by the introduction of such substances into the blood as favoured the production of molecules of transformation. The paper was very elaborate, and commended a large share of attention.—*Monthly Journal of Medical Sciences*.

On the Structure of the Middle Coat of Arteries.—By Mr. DRUMMOND.

At one of the Edinburgh Physiological Society's meetings Mr. Drummond showed several specimens of the middle coat of the aorta in the ox, for the purpose of demonstrating that the fibres have a striated appearance, which might cause them to be mistaken for muscular

fibres, but that in reality they resemble the fibres of the ligamentous nuchæ, or the yellow elastic fibre. Under a high power they exhibit numerous cup-shaped depressions, arranged in linear series, to which the striated appearance is owing. He also showed that the structure described under the title of the fenestrated coat of Henle, as it occurs in the middle coat of the aorta of the ox, is formed by the amalgamation of the network of the yellow elastic fibres, the fenestræ or perforations being merely the remains of the areolæ between the fibres. The fibres which form the coat frequently have a striated appearance.—*Monthly Journal of Medical Science*, May, 1852.

PRACTICAL MEDICINE.

Signs of the Scrofulous Habit.—By Dr. TYLER SMITH.

The author contests the general, and we believe correct opinion, that the engorgement of the lymphatic glands, seen in feeble children, is a constitutional affection. He states that in his opinion the disorder is at first local only, and does not depend on any specific constitutional taint, and therefore that these enlarged glands are not to be received as evidence of a scrofulous habit. He, however, mentions one which he considers an unfailing sign of scrofula in young children. It consists of enlargement of the fingers, particularly to the first and second phalanges. The tumidity is chiefly seen over the metacarpal bones, the joint remaining of the natural size or nearly so. The swelling is soft, but not oedematous, and evidently consists of infiltration amongst the deeper structures of the finger. The surface is pale and shining, conveying the impression of semi-transparency when the tension is great. Unless in the advanced stages, there is no pain; the last phalanx is seldom affected, and the point of the finger appears by comparison smaller than usual. The seat of this curious change appears in the first instance to be in the periosteum, and sometimes enlargement of the finger begins a few weeks after birth. Whenever the puerile finger is morbidly enlarged in the manner described, the scrofulous constitution may be anticipated; and the author believes the tumid finger to be the earliest indication of this state presented by young children. When it is observed, the subjects of it require that every exertion should be used to remedy the general debility, of which it is the certain and unmistakable sign.—*Lancet*, May 15.

SURGERY.

Charcoal Cushions for Deodorization.

Mr. Howell makes the useful suggestion that the unpleasant and injurious effects of urinary and other discharges may be obviated by the use of charcoal bags, he says:—A. S.—, a patient under my care in the Hackney Union Infirmary, has for some time “passed everything under her,” and thereby become a nuisance and cause of complaint to the other patients in the ward. Eleven days ago, I adopted the plan of placing beneath her a calico-bag two feet square, partially filled with Irish peat-charcoal, so as to form a sort of cushion and absorbing medium. It has had the happy effect—which

continues even now, without any necessity for changing the charcoal—of completely neutralizing all unpleasant odour; and if the bed becomes partially wet, all the offensive ingredients are absorbed and neutralized by the charcoal, which thus is a most simple means of remedying a great nuisance, and one that requires the most strict attention, at best, to prevent; and that attention is often difficult, and always expensive, to procure. In cases of incontinence of urine particularly, and indeed all attended with foetid discharges, cancer, compound fractures, &c., this plan, or some modification of it, might be adopted with advantage.—*Lancet*.

Fracture of the Anterior Inferior Spinous Process of the Ilium.—By Dr. ASHEY, Virginia.

The subject of this rare accident was a negro lad, aged 19, who, while carrying a pail of water on his head, suddenly stepped into a deep hole. He immediately became disabled in the right leg, especially in the attempt to flex the thigh as in walking. There was no distortion, lengthening, or shortening of the limb, so that the author decided that there was no fracture, much against the conviction of the patient, who declared that he heard something give way.

However, on elevating the leg at right angles to the body, and letting it down suddenly, the author for the first time heard a crepitus, but the sound could not be produced by any other movements, for which reason he was doubtful as to the locality of the fracture. It could not be the cervix because no pain was referred to this joint; neither were there swelling or other symptoms of that accident. Further examination cleared up the difficulty, as the author was able to seize the fractured bone, which was evidently the anterior superior spinous process, separated from the ilium. The treatment was simple, and in four weeks the boy was walking about.—*Philadelphia Medical Examiner*.

Correspondence.

O V A R I O T O M Y .

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In the *Provincial Medical and Surgical Journal* of October 30th, 1850, you published a report of a successful case of ovariectomy, performed by me at the Taunton and Somerset Hospital, Feb. 19th, 1850. The girl has called on me four times since, at intervals of about six months, and was at my house on Wednesday last, July 7th. She is in perfect health; catamenia regular. Thinking such cases should be watched for some years, and the state of health reported from time to time, I am induced to request the favour of your inserting this note in your next journal.

I am, Sir, yours obediently,

C. H. CORNISH. F.R.C.S.E.

Taunton, July 12, 1852.

Medical Intelligence.

TESTIMONIAL OF RESPECT TO DR. GRABHAM.

It is always pleasant to observe a successful issue to legitimate toil. In relation to an old and valued member of our Association, it affords us much pleasure to make the following extract from the *Chelmsford Chronicle* of the 25th ult.:—

“We noticed last week the presentation of valuable plate to Dr. Grabham and his family by the clergyman of Rochford, and the parishioners generally. On Saturday last, Dr. G. experienced a similar demonstration of kindness, on an extended scale, from very numerous contributors, in whose name the Bishop of Moray and Ross, attended by a considerable number of the clergy and gentry of the district, presented Dr. G. with a splendid silver epergne, of exquisite workmanship, bearing the following inscription:—

‘Presented to
John Grabham, Esq., M.D.,
On his leaving Rochford,
As a mark of Gratitude for professional services,
And a token of Affection
From many sincere Friends.
June, 1882.’”

RECOVERY OF MEDICAL FEES FROM DECEASED PATIENTS' FRIENDS, WITHOUT ADMINISTRATION.

An action of great importance to the medical profession was lately brought in the Brompton County Court, whereby the practicability of recovering their fees after the decease of patients was shown, and also the necessity of their fairly understanding to whom they are to look for payment in the event of death. The plaintiff, Mr. Ince, is a surgeon residing in Pimlico, and the defendant is an elderly lady named Spencer, sued in her capacity of executrix to her deceased mother, who was indebted to plaintiff to the amount of £13. 2s. 6d. An objection was at once taken to the summons by defendant's solicitor, Mr. Roberts, on the ground that Miss Spencer was not an executrix, her mother leaving nothing to administer to. Mr. Ince said the defendant called upon him, and asked him to visit her mother, who was lying dangerously ill. He attended her, and about twelve months afterwards he was requested to send in his bill instantly by Miss Spencer. Knowing them to be respectable people, he did not do so until Christmas, the usual time for medical men to send in their accounts. After this he waited some time, and sent a note. No notice being taken of this, he sent a person for the account, who brought word back that defendant's mother had previously paid witness ten pounds of the account. He, Mr. Ince, then called, and Miss Spencer told him the same tale, and said she would not pay twice over. He asked her to produce some receipt or evidence of his having been paid. This defendant could not do, and offered to pay the balance of ten pounds if he would give a receipt in full. Defendant also denied that her mother had left any property. He pointed out several pieces of furniture to Miss Spencer, and remarked to her that they were surely her mother's property. Can positively swear he never received one penny from the deceased or defendant. The furniture in defendant's house is worth £300 or £400. By Mr. Roberts: My

books are entered for Mrs. Spencer, but, out of respect for age, the bill was made out to Miss Spencer. Miss Spencer examined by Mr. Roberts: I am perfectly convinced that the plaintiff's account has been partly paid. I searched the house for the receipt, but in consequence of having burned all my mother's papers, it could not be found. My mother did not leave a vestige of property, and I have not taken out letters of administration. The expenses of the funeral were paid by me partly out of an annuity of my mother's. It was not by my wish Mr. Ince attended my mother, and I merely acted up to my mother's instructions, in telling him my mother wished to see him. By Mr. Jones: My mother left about ten sovereigns. She had no other property. The furniture in the house was all mine. I purchased it out of the produce of my school. I purchased the house for about £400 out of my savings. My mother told me she was going out to pay Mr. Ince, and I am certain she paid him £10. The Judge said: There is no evidence as to defendant being executrix. But that I will amend. As to plaintiff having been paid, there is not a tittle of evidence, and I believe his statement to be true. I consider plaintiff is entitled to a verdict, on the ground of defendant having herself employed him. Verdict for plaintiff, and costs.

PROFESSOR RECAMIER.

Lately, in his 78th year, of pulmonary apoplexy, suddenly expired this bright ornament of the medical profession, in France. His energies were unimpaired to the last, and within an hour of his death he was engaged in consultation with Professor Cruveilhier on a difficult case of practice.

Recamier's name is too well known amongst us to require our enumeration of the many improvements he has suggested to medical science, even if this were the place to do so, but the aid he has afforded us in treating surgically the diseases of women, is too important to be passed over entirely without notice, even in this short sketch, as he has thereby laid the foundation of a new pathological form of study.

Simple and unostentatious in his manner of life, so did he desire that his obsequies should be unattended by pomp or display; but both rich and poor flocked to his tomb, to show the last public token of respect to their mutual benefactor—for with him charity and science were ever closely associated.

The Faculty and the Academy of Medicine each sent deputations to do him honor; professors of eminence, many of them his pupils, gathered round his remains; and Trousseau, Gibert, and Maisonneuse, only spoke the deep feelings of all present in their eloquent orations over his tomb. Rich and poor—all have lost a friend; and it was the loss of so virtuous a man which filled with emotion and wrung with anguish many a brow too much accustomed to the world to feel the stern severities of grief.

APPOINTMENTS.

Mr. Cæsar Hawkins has been appointed President of the Royal College of Surgeons, and Messrs. James Luke, Surgeon to the London Hospital, and Mr. Robert Keate, F.R.S., were appointed Vice-Presidents of the College.

Mr. Bransby Blake Cooper has been appointed Hunterian Orator.

QUEEN'S HOSPITAL, BIRMINGHAM.

At the Monthly Board of the Council of the Queen's College at Birmingham, held on Tuesday last, at which the Principal, Lord Lyttelton, presided, Mr. Alfred Freer, of Stourbridge, was unanimously elected a Fellow

of the College under the provisions of the Supplemental Charter.

MILITARY.—Dr. Piper, for many years surgeon to the Provisional Battalion at Chatham, has been appointed medical officer to the Military Prison at Fort Clarence.

NAVAL.—Surgeon John Andrewes (a) (1841) to the *Meander*, 44, at Chatham. Assistant-Surgeon James S. Ayerest (1847), from the *Queen*, 116, at Devonport, to the *Meander*.

UNIVERSITY OF CAMBRIDGE.

The degree of M.D. has been conferred on Thomas Lockley, and A. W. Barclay, of Caius College.

ROYAL COLLEGE OF PHYSICIANS.

The undernamed gentlemen were admitted members on June 25:—Dr. Gore, Worthing; Dr. Schulhoff, Suffolk Place, Pall Mall East; Dr. Winn, Finsbury Square. Also Dr. Dunhill, York, and Dr. Hyams, Duke Street, Liverpool, were admitted Extra-Licentiate.

The following gentlemen were admitted Fellows on July 9th:—Dr. Boyd, Wells, Somerset; Dr. Fuller, Manchester Square; Dr. Hennen, Upper Southwick Street; Dr. Jenner, Albany Street; Sir Benjamin F. Outram, K.C.B., Hanover Square; Dr. Rowland, Woburn Place; Dr. Sieveking, Bentinck Street; Dr. Walshe, Queen Anne Street.

MIDWIFERY BOARD.

At a meeting of the Council of the Royal College of Surgeons, on Thursday afternoon, the following physician-accoucheurs were elected the Examiners in Midwifery to the College, in pursuance of the recent Charter—viz., Dr. Farre, Dr. Reid, and Dr. Oldham.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 2nd instant:—Timothy Doyle, Kilkenny; Wm. Mitchell Firth, Army; Benjamin Godfrey, Romsey, Hants; Tom Smith Hewitt, Nottingham; Edward A. G. L. Lundy, Hon. East India Company's Service; Albert Massey, Camberwell; John Thomas Muriel, Ely; Richard Bird Nason, Nuneaton, Warwickshire; Robert Taylor, Botesdale, Suffolk; Charles White, Doncaster, Yorkshire.

The following gentlemen were admitted members on the 9th instant:—Augustine Batt, Witney, Oxfordshire; Frederic Carter, John Caudley, Hedon, Yorkshire; Thomas Croudace, Sunderland; John Wells Fletcher, Earls Croome, Worcestershire; James Ford, Australia; Griffith Griffith, Taltreuddyn, Merionethshire; Alfred Adams Mantell, Bitton, Gloucestershire; William Roocraft, Wigan, Lancashire; Wm. Waters, Dublin.

The following gentlemen were admitted members on the 12th instant:—Thomas Anderson, Chorlton-upon-Medlock, Lancashire; Edward Atkinson, Little Woodhouse, Yorkshire; William F. Bellin, Great Yarmouth, Norfolk; Theodore Grant Cresy, Australia; Joseph Hazard, Hampstead Heath; Francis Marchant Laidman, Exeter; Henry Lowndes, Liverpool; William Clarence Matthews, Longsight, Manchester; Richard Ratcliffe, London; William Henry Rean, Plymouth; Thomas Thomson, Brunswick Place, Regent's Park.

FELLOWSHIP EXAMINATIONS.—The following gentlemen have just passed their examinations in Classics,

Mathematics, and French, viz.:—Archibald Childs, Bungay; Edward Gylles Crooke, Leyland, near Preston; Peter Yeames Gowland, Finsbury Square; Harvey Ludlow, Paternoster Row; Thomas Edward Pearce Martin, Tooley Street; William Boyd Moss, West Smithfield; George Robert Skinner, Bath; S. M. C. A. Anderson Smith, Paradise House, Kilburn.

The following members of the College have also been admitted to the Fellowship, under the provisions of the recent charter:—Charles Abhavas, Birmingham; William Bartlett, Notting Hill; Thomas Barrett, Bath; George Beaman, King Street; William Henry Bellat, Stockport; George Bottomley, Croydon; George Burt, New Bridge Street; George Bury, Whetstone; Alexander B. Chisholm, Wimpole Street; Charles Collambell, Lambeth; Robert Dunn, Norfolk Street; Ralph A. Frogley, Hounslow; Michael Foster, Huntingdon; Walter Griffith, Bloomsbury Place; Thomas Hewlett, Harrow; Thomas Hunt, Alfred Place; Francis Hutchinson, New Bridge Street; John Jones, Upper Clapton; William Kershaw, Royton; John A. Lloyd, Bath; Thomas Lloyd, New Basinghall Street; David P. Maurice, Marlborough; Robert Norton, Westbourne Grove; John Perry, Eaton Square; John Evans Riadore, Harley Street; Richard R. Robinson, Camberwell; Edward O. Spooner, Blandford; James Startin, Saville Row; John Soper Streeter, Harpur Street; William Tarleton, Birmingham; John Thompson, Biggleswade.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 1st July:—Donald Fraser, London; Charles William Goodall; Robert Grundy, St. Helens, Lancashire; William Harbord, Wainfleet, Lincolnshire; James Innes M'Intosh; George Moore, Tunbridge Wells; George William Noad, Newfoundland; John Watkin Phillips.

Gentlemen admitted members on the 8th July:—Clarence Cooper, Brentford; Thomas Potter Johnson, Congleton, Cheshire; Thomas Spencer, East Shelton, Leicestershire.

OBITUARY.

July 2nd, at Kilmuir, Argyllshire, in his 80th year, Thomas Thomson, M.D., F.R.S.L. and E., etc. Regius Professor of Chemistry in the University of Glasgow.

July 1st, at Newcastle-upon-Tyne, Noel Thomas Smith, M.D., aged 83.

ERRATA IN MR. FOSTER'S PAPERS.

In the table of contents, last *Journal*, there is an error in the name of the author. It should have been "Two Cases of Vitiligoidea, by M. Foster, Esq., Huntingdon," instead of W. Foster; also in the heading of the paper in the *Journal*, the same mistake occurred. Page 139, col. 2, 13 lines from the bottom, for *external* read *sternal*.

TO CORRESPONDENTS.

Communications have been received from Dr. Merei, Dr. Cotton, and the Birmingham Pathological Society.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

PROVINCIAL
MEDICAL & SURGICAL ASSOCIATION.

TWENTIETH ANNIVERSARY MEETING.

THE Association held its Twentieth Annual Meeting at Oxford, on Wednesday, the 21st, and Thursday, the 22nd of July, 1852.

The following gentlemen recorded their names in the book kept for the purpose. The total number present was about 300 :—

George Jenks, M.D., Brighton; James A. Ogle, M.D., Oxford; Sir Charles Hastings, M.D., Worcester; John S. Soden, M.D., Bath; John Forbes, M.D., London; James Crang, Esq., Timsbury; W. A. Greenhill, M.D., Hastings; Richard Flint, Esq., Stockport; Thomas Radford, M.D., Manchester; John Elliott, Esq., Kingsbridge; C. Radclyffe Hall, M.D., Torquay; James Tunstall, M.D., Bath; J. H. Walsh, Esq., Worcester; W. Colborne, Esq., Chippenham; John Higginbottom, Esq., Nottingham; Joseph White, Esq., Nottingham; Farnham Flower, Esq., Chilcompton; Charles T. Carter, Esq., Hadley, Middlesex; William Newnham, Esq., Farnham; Chas. Bailey, Esq., Cliffe, Chippenham; Thomas Nunneley, Esq., Leeds; Edwd. Wallace, Esq., Carshalton; John Grabham, M.D., Islington; George Humphry, Esq., Cambridge; John Kirkman, M.D., Melton, Woodbridge; Frederick T. Wintle, M.D., Warneford Asylum; John Martin, Esq., Oxford; Thomas Hunt, Esq., London; John Rose Cormack, M.D., Putney, London; Jas. Edwards, M.D., Bernarth, Conway; Richard Hansard, Esq., (Hon. Sec.,) Oxford; Edward R. Owen, M.D., Oxford; Alexander Henry, M.D., Maidstone; Robert Wake, M.D., Southwold, Suffolk; Joseph C. Cookworthy, M.D., Plymouth; T. L. Surrage, Esq., Clifton; J. Stedman, Esq., Guildford; Peter Martin, Esq., Reigate; Archibald Robertson, M.D., Northampton; John Griffith Leete, Esq., Thrapstone; W. H. Ranking, M.D., Norwich; James Young, Esq., Wells, Norfolk; William Gill, Esq., Nottingham; H. Martin Holman, M.D., Hurstpierpoint; Henry Alford, Esq., Taunton; C. H. Cornish, Esq., Taunton; Robert Marchant, Esq., North Curry, Somerset; H. W. Randolph, Esq., Milverton; W. E. Gillett, Esq., Fairwater, Taunton; Francis Henry Woodforde, M.D., Taunton; Richard L. Pennell, M.D., Cheriton Bishop; C. F. J. Lord, Esq., Hampstead; Robert Fookes, Esq., Stockport; Edward Howell, M.D., Swansea; John Churchill, Esq., London; Wm. Matterson, jun., Esq., York; Harry Lupton, Esq., Thame; J. Armitage Pearson, Esq., Woolton, near Liverpool; Ellis Jones, Esq., Liverpool; Crosby Leonard, Esq., Bristol; George Turner, M.D., Stockport; George Downs, Esq., Stockport; Geo. Edwards Esq., Wolverhampton; Harrington Tuke, M.D., Cheswick; W. James, Esq., Bristol; James Heygate, M.D., Derby; Geo. Vicary, Esq., Warminster; Richard Alford, Esq., Tewkesbury; M. Battel, Paris; John

Barclay, M.D., Leicester; D. Barclay, M.D., London; John Motherell, M.D., Castledery, Ireland; John Haddy James, M.D., Exeter; T. G. Hake M.D., Bury St. Edmunds; J. Thurnam, M.D., Devizes; C. P. Collins, Esq., Dulverton; M. Shurlock, Esq., Eynsham; G. S. Ogilvie, Esq., Stapleton, Bristol; E. S. Mayor, Esq., Bristol; John S. Bartrum, Esq., Bath; Hugh W. Diamond, M.D., Surrey County Asylum; W. D. Husband, M.D., York; James P. Sheppard, Esq., Worcester; Thomas Workman, Esq., Bayswater; William Gibbon, Esq., Kettering; C. B. Nankiville, M.D., Torquay; R. Giles, M.D., Oxford; Comte de Montizon; Edward Mainwaring, M.D., Bournemouth, Hants; Dr. Ross, Madeira; Cordy Burrows, Esq., Brighton; Chas. W. Bell, M.D., Manchester; J. Sharpe, Esq., Warrington; Peploe Cartwright, Esq., Oswestry; Thomas Smith, M.D., Cheltenham; William Philpot Brookes, M.D., Cheltenham; Forbes Winslow, M.D., London; Francis Sibson, M.D., London; Thomas Hodgkin, M.D., London; George Bottomley, Esq., Croydon; John Probert, Esq., London; G. Bury, Esq., Whetstone; Henry Lee, Esq., London; Richard Woodhouse, M.D., Reading; Edgar Sheppard, Esq., Enfield; F. C. Batt, Esq., Abergavenny; T. W. Jeston, Esq., Henley-on-Thames; Edward Ray, Esq., Dulwich; Rev. D. Bell, Bleasdale Parsonage; James Williams, Esq., Apsley Guise, Woburn; Henry W. Rumsey, Esq., Cheltenham; Gustavus Foote, Esq., Kington, Herefordshire; Wm. Hey, Esq., Leeds; D. Rice, Esq., Stratford-on-Avon; B. Rice, Esq., Littlemore; J. Hitchman, M.D., Derby County Asylum; George Burrows, M.D., London; J. Bowling, Esq., Hammersmith; G. H. Haslop, Esq., Buckingham; Owen Roberts, M.D., St. Asaph; Bell Fletcher, M.D., Birmingham; Eason Wilkinson, M.D., Manchester; George Southam, Esq., Manchester; William James Wilson, Esq., Manchester; W. W. Williams, M.D., Gloucester; William Ley, Esq., Littlemore; John J. Field, M.D., Torquay; E. Ambler, Esq., Stalbridge; Caleb Williams, Esq., York; Thomas Grimwood, Esq., Walton; T. Herbert Barker, M.D., Bedford; A. Hamilton, Esq., Amphill; John William Harriss, Esq., Exeter; William Clapp, Esq., Exeter; Stanton Wise, M.D., Banbury; Hamilton A. Roberts, Brynmewrig, Bangor; Forbes Winslow M.D., London; Thomas Tapley, Esq., Great Torrington; Charles Chadwick, M.D., Leeds; James Turnbull, M.D., Liverpool; Thomas Paget, Esq., Leicester; Charles Mayo, Esq., Winchester; Charles Mayo, jun., Esq., Winchester; Jas. Mayo, jun., Esq., Winchester; Henry James Stokes, M.D., Islington; Henry Cooper, M.D., Hull; Robert Hardy, Esq., Hull; Augustus Eves, M.D., Cheltenham; W. Budd, M.D., Bristol; Charles Cowan, M.D., Reading; Geo. B. Clark, M.D., Colchester; T. Ogier Ward, M.D., Kensington; A. D. Dunstan, Esq., Holmes Chapel, Cheshire; Edward Pope, Esq., Tring; Dr. Duke, Rugby; William Wilson, Esq., Brighton; W. H. Duncan, M.D., Liverpool; C. C. Wallis, Esq., Castle Cary; Richard N. Strew, Esq., Steyning; G. H. Fosbroke, Esq., Bideford; J. G. Rusher, Esq., Pershore;

Joseph Toynbee, Esq., London; Richard Eaton Rusher, Esq., Oxford; Thomas Sawyer, Esq., Clifton; James George Davey, M.D., Northwoods; Joseph Lancaster, Esq., Clifton; Paul William Swain, Esq., Devonport; Phillip Grubb, Esq., Warminster; Benjamin Gilson, Esq., Halstead; Henry Pocock, M.D., Coventry; Thos. Clark, Esq., Wellingborough; Thomas Mellor, Esq., Manchester; James Nash, M.D., Worcester; Samuel Crompton, Esq., Manchester; James Paxton, M.D., Rugby; P. Miller, M.D., Exeter; R. Burridge, M.D., Taunton; B. Chevallier, M.D., Ipswich; Wm. C. Trotman, M.D., Clifton; W. R. Kelly, M.D., Taunton; H. Kent, Esq., Wrotham, Kent; J. W. Keilgell, Pangbourn, Berks; J. W. Metcalfe, Esq., York; G. Curme, Esq., Dorchester; E. H. Ambler, Esq., Late Stalbridge; Duncan Sinclair, M.D., Halstead; H. Pout, Esq., Yalding; H. M. Gould, Esq., Wateringbury; S. Hare, Esq., London; T. Shapter, M.D., Exeter; W. H. Michael, Esq., Swansea; A. W. Davis, M.D., Presteign; J. W. Workman, Esq., Reading; T. L. Walford, Esq., Reading; W. T. White, Esq., Kempsey; J. Mash, Esq., Northampton; T. Bull, Esq., Great Grimsby, Lincolnshire; W. Eddowes, Esq., Pontesbury, Salop; John Conolly, M.D., Hanwell; G. N. Robinson, M.D., Leadwell; R. Turner, Esq., Tunbridge Wells; H. Veasey, Esq., Woburn, Bedfordshire; J. Hodgson, Esq., London; E. Waters, M.D., Chester; J. Soden, Esq., Bath; A. Prichard, Esq., Bristol; A. B. Rye, Esq., Banbury; T. Thompson, M.D., London; J. Frankerd, Esq., Langport; W. W. Munckton, Esq., Curry Rivel, Somerset; F. N. Gosling, Esq., Worcester; E. Hussey, Esq., Oxford; G. Cowley, Esq., Winslow, Bucks; F. Symonds, Esq., Oxford; J. Ormond, Esq., Bath; Thos. Lightfoot, M.D., London; E. Daniell, Esq., Newport Pagnell; G. F. Paxon, Esq., Cranfield, Beds; J. Faircloth, Esq., Northampton; G. W. Hastings, Esq., Temple, London; James Stilwell, Esq., Uxbridge; A. Stilwell, M.D., Hillingdon; J. W. West, M.D., Dorset; G. May, Esq., Reading; R. Jones, jun., Esq., Astrop; R. Jones, Esq., Brackley; J. McCaragher, M.D., Chichester; J. F. Lamb, M.D., Philadelphia; J. C. Williams, M.D., Nottingham; J. H. Pring, Esq., Weston-super-mare; W. Barker, Esq., Wantage; E. J. Hayward, Esq., Wantage; J. Whiting, M.D., Lynn; C. E. Sheppard, Esq., Worcester; &c., &c.

The preliminary meeting of the Council took place in the Town Hall at seven o'clock on Tuesday evening, and the

FIRST GENERAL MEETING

was held, by the permission of the Rev. the Vice-Chancellor of the University, in the Convocation House, at ten o'clock. Shortly after the time appointed for meeting,

Sir CHARLES HASTINGS moved that Dr. Jenks, of Brighton, take the chair. (Applause.)

Dr. JENKS accordingly took the Presidential seat, and then addressing the meeting, said it devolved on

him to take the chair, and formally open the proceedings, and then resign it (after having held it for the usual term of one year,) to his successor; before doing so, however, he had to express his grateful sense of the honour done him in his appointment as President at the last meeting, and the high satisfaction it had afforded him to preside, for so long a period, over a body alike so numerous and influential as the one he was now addressing. He would not detain them by giving an account of the transactions of the past year, as these would come regularly before them in the Report of the Council, but he could not refrain from congratulating them on the successful progress and onward march of their Association. The great gratification which he experienced at meeting them in this ancient city was greatly diminished by the lamented decease of the late Regius Professor of Medicine in this University, Dr. Kidd. That estimable and respected man, being far advanced in years, was most desirous of having a meeting of the Association in Oxford before he paid the debt of nature, but unfortunately his wish had not been realised; they had, however, the satisfaction and consolation of knowing that his intention would be fully carried out by his successor the present Regius Professor, Dr. Ogle, a gentleman who had been recommended by Dr. Kidd to preside over this, their twentieth anniversary. Under his auspices, and those of the many gentlemen he saw around him, he (Dr. Jenks) could promise them a very successful meeting. It did not befit him, as he had previously remarked, to detain them with any lengthened remarks, and in vacating the chair he would say that he should remember the honour conferred upon him by his appointment to the office of President as long as life was spared him. (Applause.) With the best wishes for their health and happiness, he begged to introduce to their notice his successor Dr. Ogle. (Much applause.)

Dr. OGLE having taken the Presidential chair, amidst very hearty applause, rose and spoke as follows:—

GENTLEMEN,—The introduction with which my predecessor in this office has just favoured me, far from being a matter of simple form and courtesy, is, as I am well aware, a measure no less of need than propriety.

There are many here to whom I am equally in name and person unknown.

When in the early days of this Association those gentlemen to whose exertions it mainly owes its origin found here in Oxford that friendly reception, that earnest encouragement, and that decided support, which my much esteemed and deeply regretted friend, the late Dr. Kidd, both proffered and supplied to them, I was myself in deepest affliction; death had very recently invaded my home, and had bereaved me of what I there held dearest. That I might the better discharge the domestic duties which had thus devolved on my sole care, I withdrew at once and entirely from all engagements which would entail upon me distant sojourn and lengthened absence from my home and family; and thus it was that the pleasure and profit which the annual meetings of this Association supply to its members have been lost to me, and that I am a

stranger to so many of my professional brethren, from whose acquaintance I might, under happier circumstances, have derived both gratification and instruction. Yet, gentlemen, I pray you to believe that though so late in joining the Association, I was neither opposed to the purposes it contemplated nor have I been indifferent to its progress and eventual success. At the suggestion of that revered friend and associate whom I have already named, whilst yet he was in life and happy in anticipation of this day's meeting, the Council of the Association paid me the compliment of inviting me to preside on this occasion, a compliment which I am quite sensible I mainly owe to a courteous respect for my years and academic position; yet, therein I am nevertheless well content, assured as I am that no such considerations would have secured to me the commendations of the one party nor the choice of the other, had I been deemed personally unworthy of this distinction; and although the partial kindness of friends but too frequently misjudges the capacity of one to whom they are attached, I shall venture to say, that in so far as an earnest regard for the honour and dignity of our profession,—an indignant contempt of those audacious impostors of past and present time professing medicine, whose atrocious frauds are surpassed only by the sordid motives which prompt them—frauds alike injurious to an honourable calling and to the welfare of the community,—so far, I say, as these sentiments may entitle any one to such an honour, I may vindicate for myself the occupancy of this chair, without fear of challenge or of molestation from any quarter.

Under the circumstances in which I am placed, you will concede to me your indulgence, and pardon me the egotism in my proceeding to say of myself that I am, and always have been, the opponent of all unnecessary impediments to the acquirement of professional privileges; and that as regards the discipline and economy of the medical community, whether as determined by legislative enactments, or adopted by general consent on the principle of mutual concessions, I am an advocate of the freest policy which is consistent with the nature of our institutions, and conducive to the common interests of us all; but I scruple not to add that we shall do well to bear in mind, that so long as in His inscrutable wisdom, the all-wise and all-benevolent Author of every blessing sees fit to distribute with unequal hand the gifts of talents, means, and opportunities; so long must inequalities exist among us, which it is neither practicable nor desirable to efface. This remark, I am well aware, would come from me with singular ill grace, were I not indeed of full and honest purpose to promote whatever may conduce to the general welfare of the profession, and to do away every hindrance to open lists and a fair field for all.

Without making any special reference to, or entering into discussion of, the several proposed bills and new charters at this time before the medical public, I would observe that it is hopeless to effect any permanently satisfactory arrangements, until the statutes of our academic institutions have been revised, and their proceedings brought more into unison or parallelism with

each other than is at present the case; for how is it possible that without a sense of its patent injustice can equal respect be challenged, and equal privileges claimed for academic distinctions to be had at one university at the cost of a small pecuniary payment, but which at another are to be obtained only by residence and a course of study to be continued during years, and a proficiency to be tested by a severe and searching examination.

I will presently set forth the main features of our system here in Oxford, meanwhile I do not hesitate to say that I deem the cost of education in this place not simply a very serious drawback on our usefulness, but in so far as it can be avoided, a palpable wrong to the community. These sentiments, gentlemen, have not their origin in the desire of saying something from this chair which may commend me to your favourable opinion, by an affectation of candour and honest judgment. I am happily able to show, that long before I could have had thought of this occasion, or opportunity of setting forth such opinions, I had submitted them to the consideration of Her Majesty's Commissioners of this University, and had presumed to suggest such measures for diminishing the grievance alluded to and for extending as widely as possible the advantages of our institutions as I deemed of just and practicable application, and by reference to the report which has been lately published under authority of these gentlemen, it will be found that I am entitled to claim credit for sincerity in the declaration which I have been bold enough to make. I am happy in being able to add, that there are many members of the academic body who, taking a like view of the matter, are equally with myself anxious to effect changes whereby the portal of this great national institution may be thrown more widely open, and the liberal bounty of our many founders and benefactors rendered in fullest measure productive of the good which their piety, their patriotism, and their benevolence contemplated. I should, however, be guilty of a great injustice to many very amiable and excellent men, whose intelligence I am constrained to acknowledge, and whose integrity it were worse than idle to dispute, were I to represent the differences on this point existing among us in this place as a contest of selfish interests against public rights; or of bigot opinion against honest conviction; the truth is, that the system transmitted to us from a distant date, and well-suited to the state of society a century or two since, is become, through those changes which time in flourishing states ever rapidly brings about, in some particulars obsolete; yet so long has it been an honest boast to us, so long has it been the acknowledged instrument of general good, as many an honoured name attests—statesman, divine, jurist, philosopher, poet, and last, not least, physician—that well indeed may such as have long been used so to regard it, claim our forbearance ere we too rudely condemn that caution, which, as it were, fears to quit the long-trodden, secure and well-known foot-path for the broad but untried highway to which they are invited. These observations apply especially to the regulations by which the advantages of the University

are restricted to the members of the existing collegiate establishments. Apart from such considerations, our proceedings (and I refer now specially to those in medicine) are in my judgment of careful forethought and of just enactment. The statute which regulates them requires that candidates for the degree of Bachelor in that Faculty should have kept residence and have undergone examinations in every respect the same as in the case of such students as seek a Degree in Arts. This is a four years' course, *i.e.*, sixteen terms, during twelve of which at least the candidate must have resided strictly within the walls of his college. On the successful completion of this course, he is required further to have given three entire years to the diligent study of medicine, in attending the lectures of teachers of repute in the various subjects of professional instruction and the clinical practice at some hospital "*melioris notæ*," of large accommodation and well-frequented access, the candidate's choice being fettered by these conditions alone, he is in other particulars at full liberty to consult his own convenience, and act by his own judgment in the matter. We deem it unadvisable to encourage his further stay in Oxford, and even unjust to enforce it, from the conviction that the metropolitan schools, or those of large and populous towns or districts alone can supply to the student opportunity of becoming familiar with acute disorders, and of witnessing the variety in mode which disease in chronic form exhibits.

On testimony that our candidate has so far duly complied with the requisitions of the Statute, he is subjected to an examination, public so far as regards the admission of academic graduates in whatever faculty, and members of the medical profession legally authorized to practice, of whatever grade and in whatever department.

The subject matter of examination comprises anatomy, physiology, pathology, and therapeutics, with chemistry and botany, so far as these illustrate the art of medicine; and lastly, the Statute requires that the examiners be careful to test the candidate's acquaintance with the writings of Hippocrates, Aretæus, Galen, and Celsus. By tacit understanding this is practically limited to the work of Celsus, the aphorisms and epidemics of Hippocrates, those parts of Aretæus which treat of the signs of acute and chronic disease, and that portion of Galen in which the uses of the parts of the body are discussed. I need make no observation on the first four items of this list—the proper and essential subjects of medical study. Some may deem acquirements in chemistry and botany of less value than that at which we rate them; but I feel well assured that no intelligent practitioner would do otherwise than approve as of most just and reasonable demand, that proficiency in these disciplines which my judicious friend and colleague, Dr. Daubeny, exacts. And in regard to acquaintance with the ancient writers above named, we are to bear in mind that our candidates have already gone through the exercises and examination for a degree in arts, implying a certain familiarity with Greek and Latin literature, and that consequently no very heavy additional burthen is imposed upon them; and as to its

utility, I shall not here dilate upon this point, but refer you to the very curious and interesting facts bearing on the question related by that accomplished scholar and very intelligent physician, the late Dr. Joseph Adam, in his life of Mr. Hunter.

The Examiners are in number, three, Doctors of Medicine, Graduates of Oxford, *viz.*,—the Professor holding that chair, with which Her Majesty has lately been pleased to honour me, and two assessors, nominated by the Vice-Chancellor, and subsequently approved by convocation. At this time all three are Fellows of the London College of Physicians. On their approval of the candidate's sufficiency a licence to practise, with the degree of M.B., is conceded to him; but he has yet to wait a second three years, making in the whole ten from his matriculation, when, with experience so matured, on satisfactory testimony to his moral character, he is at length admitted to the Doctorate, and left to his own course. The Statute has now been in force seventeen years. I deem its provisions to be in theory unobjectionable; and I am happy in being able to add that in practice it has proved successful. With very few exceptions, all our medical graduates since the above date have, with a view to practise within the liberties of the London College, submitted themselves to a second examination at the Censor's Board of that institution; and in no instance has our judgment of the candidate's sufficiency been reversed.

I have ventured to occupy you with these details from various considerations, among which is the natural desire to secure to our graduates the just respect of their professional brethren; and to obviate, so far as regards our proceedings in medicine, the unfavourable impressions which the exclusiveness of our Collegiate system, and certain prejudices and observances among us, elsewhere obsolete, have a tendency to convey.

In drawing up the Statute, Dr. Daubeny and myself enjoyed the co-operation of our late intelligent friend and colleague, Dr. Kidd, whose aid and superintendence was for many years given towards carrying out its purposes; and though latterly he had withdrawn, through infirmity of advancing years, from the active duties of his professional position, he ceased not to take a lively interest in all that affected the credit and prosperity of the University, more especially in matters having reference to the faculty whose well-being had been committed to his charge. To him indeed we owe it that we are this day assembled here in Oxford. The indulgent concession of your visit hither, effected indeed at the cost of the promised gratification to our brethren at Manchester, was at his request. Alas! how unexpectedly has the purpose of the changed arrangements been frustrated! how have our anticipations been foiled. His unlooked-for decease has greatly impaired our power of suitable reception, and has entailed upon myself a mournful duty, little anticipated when I first consented to undertake that which pertains to this chair, but which, happily, is no less accordant with the usage of our Association than becoming my

own position and consonant with my inmost feelings. Permit me, then, as one having opportunity, and from whom, consequently, the just expectation of his many friends may reasonably await this debt of piety and friendship,—permit to me, I say, some few words in truthful eulogy of our much regretted friend. His position as at once Regius Professor in Anatomy and also Lee's Prælector at Christ Church, enabled him in the latter capacity to discharge simultaneously, during by far the greater part of his term of office, the duties of both trusts. Some few years since, feeling himself through infirmity and advanced life, unequal to the task, he resigned Lee's Prælectorship, under just expectation that during his remaining years indulgence would be conceded to him by the academic authorities, and the lectures of his successor at Christ Church be accepted in full acquittance of whatever might otherwise, in strict observance of the Statutes, be still due from him as Regius Professor. His years, his character, and his services to the University, well entitled him to ask, and in equal degree justified the academic authorities in granting, such boon. He was not one to neglect his charge from love of leisure, deficient sense of his duty, or disregard of its obligations. To him, as sometime Prælector in Geology, the University owes the commencement of that fame which under his successor has been so amply perfected, in the study of that science; and, whatever may have been the merit of others, he undeniably was the first to diffuse in this place a knowledge of modern chemistry. As an anatomist and in physiology, his reputation is established for patient investigation, careful observation, and sagacious conjecture. As a teacher he was eminently successful in giving an interest to his subject by a lucid arrangement of his matter, a happy facility of illustration, and a ready command of language. As regards moral and social worth; I knew him long and intimately, and in declaring my own, I give but expression to the one unanimous judgment of those among whom he lived,—that he was a gentleman of most generous sentiments, and of most upright conduct. Entire strangers to each other before I settled myself as a fellow practitioner in this place, the intercourse of years gave rise to feelings on both sides of sincere, and, I may indeed say, affectionate regard. When last I saw him, I had no thought nor even a wish to succeed him. Had he been spared to us a few years longer my own years would have forbidden my seeking the succession. We all know how unlooked for was his immediate summons, yet herein was his happiness and gain, for few among us will be found better prepared for that dread event. Of strictest integrity in his dealings with others, his scorn of all that was mean and false, was tempered only by Christian pity for those who practised evil. His talents, naturally good, were duly cultivated and matured by study—his attainments varied, justly acknowledged, and amply adequate to his position; of easy access, cheerful habit, and most agreeable conversation; he was at once to us a credit and a stay; above all, he was a Christian, in heart and hope, in faith and practice. Herein, then, be we con-

soled, relying in full confidence on the Divine assurance, that "Blessed are they who die in the Lord." One grateful task he left me, namely, the care to provide that the University should testify on this occasion to this company collectively that respectful consideration which, in truth, she has ever been prompt to show to individuals whose labours have benefitted, or whose virtues have improved their fellow men; and this, from a sense of the honour which is due to merit, and of the obligations incident to her own position, bound as she is to set forth by her own example, and by honouring that of others, every incentive to exalted patriotism, and those other social virtues, under which safeguards alone can the free development of the intellectual powers prove conducive to the welfare of mankind. In this task I neither anticipated, nor have I experienced any difficulties, seeing that that which alone could have proved a matter of embarrassment had been effected before the charge in question had devolved upon me. My brethren of the faculty of medicine concurring with me in the application, an arrangement suggested by Dr. Kidd met with favour at the Board of Houses, and, as on the occasion of the former visit of the Association, two of its then most distinguished members were admitted to the Academic Doctorate in its fullest privileges, so on the present it is permitted to me, in testimony of respect for the Association collectively, to invite to the Honorary Doctorate in Civil Law some three of its members, gentlemen by whom the compliment would be duly appreciated, and through whom, by their talents, their attainments, and their reputation, may be reflected back on the University the honour which that compliment confers. I may here state that this degree—the one to which the higher honorary admissions are now restricted,—is a distinction which the most exalted personages have condescended to accept, and those of highest reputation in literature and science have been proud to bear. It would be long to rehearse the list, adorned by names which shed a lustre on their times and country, suffice it to cite from among our own brethren those of Brodie, Alison, and Owen, very lately enrolled among the number, and that of Paris, the learned President of the London College of Physicians, who, the just pride and boast of his own University, has not declined to let us at Oxford share the honour of his name and fame.

It may easily be believed that the embarrassment to which I just now alluded, was the difficulty of selecting from among so many worthy of this distinction, the three to whom it should be awarded; but, happily for myself and colleagues, we have found escape from so invidious a task. In the correspondence of Dr. Kidd with the Council of the Association, submitted at his decease to my perusal, I found the names of three gentlemen set forth as those on whom the lot had fallen, by whose intervention I neither know nor have I been too curious to inquire. These names the faculty have most willingly accepted, no less from respect of the individuals themselves than from that which is due to the memory of our deceased friend. It will be admitted without dispute, that Sir Charles

Hastings, Dr. John Forbes, and Dr. John Conolly, are well worthy the distinction to which they are invited; and though I have no other voice in the matter than that of consent and commendation to the Vice-Chancellor, it affords me a peculiar satisfaction that the choice has favoured the three gentlemen above named; for in offering my congratulations to you, Sir Charles Hastings, and to you, Dr. John Forbes, I may revert to those days of our early manhood, when from the schools, to which a long series of illustrious names, as teachers, had secured a pre-eminence in medicine, as frankly conceded as it was fairly earned, we commenced our respective courses which have happily run so prosperously to us all; yours, gentlemen, by the merits of a just desert, mine by the favour of propitious fortune; and with you, Dr. John Conolly, to whom the praise of high and well-deserved success is equally due, may I recall those days when, snatching opportunity from amid the toils of professional duty, you were wont, at no small cost of your personal comfort and convenience, to gratify by occasional visits the circle of your friends in Oxford, of whom, alas! so few survive.

It remains only for me to add that a Convocation will be holden for these admissions at two o'clock this day in the Sheldonian Theatre adjoining the place where we are now assembled, and that it will be open to any member of this company who may be pleased to attend.

In conclusion, gentlemen, I bid you all a hearty welcome, on the part of myself and the practitioners resident in Oxford. We will do our best to make your visit agreeable to you. We trust you will accept this assurance, given in all good faith, and that you will pardon whatever deficiency our inexperience or any other untoward circumstances, may cause.

Mr. SHEPPARD, the Secretary, then read the

REPORT OF THE COUNCIL.

The time has again arrived when it is incumbent upon the Council of the Provincial Medical and Surgical Association to render an account of the proceedings of the Society during the past year, and they do so under circumstances as favourable as on any previous occasion.

It is in the first place desirable shortly to allude to the alteration of the locality in which we assemble. It is well known that Manchester was the place fixed upon at the Brighton Meeting for receiving the Association in 1852; but soon after the last Anniversary the President of the Council received a letter from the then Regius Professor of Medicine in the University of Oxford, warmly expressive of his gratification at seeing the continued advancement of the Association, and earnestly entreating that an early Meeting of the Association might be fixed at Oxford. He moreover stated that he had arrived at that period of life when the days which remained to him were few, and he entertained the hope that, before he finished his career, he might have the happiness of welcoming the Members to his Alma Mater. Moreover, Dr. Kidd proceeded further, and inquired whether by any means it could be arranged so that the Anniversary for 1852 might be held at Oxford instead of at Manchester. Under any circumstances an application coming from such a party, and enforced by such considerations, would have demanded the deliberation of your Council; but it likewise so

arose that about this time some unexpected difficulties were encountered in carrying out the arrangements at Manchester, and this induced the Central Council to communicate to the Manchester Council the strong desire which Dr. Kidd had expressed to receive the Association at Oxford. The Manchester Council were summoned together, and they recommended that the request of the Regius Professor of Medicine should be granted, as they thought it better that the Anniversary at Manchester should be deferred. The President of the Council, after this, lost no time in addressing Dr. Kidd, whose warm feelings prompted him at once to negotiate with the Vice-Chancellor of the University, who promised his aid in receiving the Association with due honour. Dr. Kidd also named his friend, Dr. Ogle, as being peculiarly fitted to undertake the office of President-elect, which office, on account of advanced years, he himself did not feel equal to. Thus the Central Council became pledged to meet at Oxford, under the auspices of the Regius Professor; and the negotiations for this purpose were scarcely brought to a close, when suddenly Dr. Kidd was removed from the scene of his earthly labours. The gloom which this mournful event cast upon our proceedings can be better felt than expressed; and for some time it was doubtful what course should be pursued, but Dr. Ogle had been recommended as the President-Elect by our deceased friend, and the profession in Oxford were still willing to do the best for our reception under the loss they had sustained; moreover, the Manchester Council were still of opinion that it was desirable to defer the Meeting at Manchester. It was therefore determined by your Council that the venerable University of Oxford had irresistible claims upon the Association, and that an Anniversary spent in her ancient Halls and Colleges could not fail to give strength and vigour to our noble Association.

Number of Members and District Branches.

Your Council are enabled to report that the number of the Members has rather increased since the last Anniversary. The number of Members who have died during the year is about twenty, and the number who have resigned is about forty, the number of new members admitted since the Brighton Anniversary is 183, and the number now upon the list amounts to 1629. Since our last General Meeting, two District Branches have been added to those before existing, one called the Midland Branch, including Derby, Nottingham, Leicester, and Lincoln; the other, the South Wales and Monmouthshire Branch, including Swansea, and the chief towns in South Wales, together with Monmouth. These new District Branches are expected to add many new Members to our ranks, as they have both been formed in districts where heretofore there has been but little exertion called forth to make the advantages of the Association known, but now, from the zealous manner in which those who have commenced these Branches are endeavouring to advance the objects of the Society, your Council are encouraged to expect further progress. The system of District Branches, it may be remembered, is found to work very beneficially, and whenever any circumstances arise which point out any locality as likely to avail itself of the advantages that result from these local reunions, your Council do not fail, as far as possible, to take steps to forward their establishment.

Finances.

The Finances may still be stated to be in a healthy state, notwithstanding a considerable number of the Members are yet in arrear. Great exertions have been made to get the Subscriptions generally paid up; but in a Society consisting of so many Members widely scattered throughout every part of England and Wales, it is found almost impossible to secure a punctual payment of Subscriptions, but the income, nevertheless, still

exceeds the expenditure, and your Council trust that by an economical use of the funds entrusted to them, there may be no pecuniary embarrassment. On the present occasion your Council will enter more into detail as to the state of the Finances, because they are desirous that no Member should be ignorant of the exact position of the Society's affairs. They will first, then, give a debtor and creditor statement of the cash received and paid by the Treasurer, and afterwards render an account, as near as can be done, of the assets and liabilities of the Association.

Publications.

Your Council since the last Anniversary Meeting have published the eighteenth volume of the *Transactions*, and the printing of the nineteenth volume is commenced. The extent and number of the communications that will be contributed at this Anniversary must very much determine the period at which the next part or volume of the *Transactions* shall be published. Some time must necessarily elapse before it can be in the Members' hands.

The *Journal* has been regularly published every fortnight. Your Council being desirous of enriching this publication by a greater number of, and more valuable reports from, Provincial Hospitals and Infirmarys, have, out of their own fund, which was instituted for the purpose of encouraging such pursuits, offered two Prizes of Twenty Guineas each, for the best series of Medical and Surgical Reports that shall be sent for publication in the *Journal* between October, 1851, and October, 1852. Already many valuable Reports have been sent in to the Editors from Provincial Hospitals, and there is every reason to expect that this department of the *Journal*, which has hitherto been scantily supplied, will receive many important contributions. As respects the general management of the *Journal*, your Council have reason to believe the Members are generally of opinion that it has improved under the present Editors. In so large a body, however, there will always be differences of opinion as to the best mode of conducting such an important element in the success of our Association as its publications. Your Council have during the year received suggestions pointing to some alteration in the publications. This is a question which

cannot with advantage be discussed in a General meeting of the Members, and your Council consider the most judicious course to pursue will be to appoint a Committee of Members to take into consideration any suggestions that may be made for improving the publications, and especially as to the Editorship of the *Journal*. This Committee may either report to the Anniversary Meeting before it rises, or may be empowered to report to the Central Council, and, in conjunction with them, to carry out any plan that they may recommend.

Medical Reform.

Your Council are glad to be enabled to report some progress in medical legislation. The new Charter which has been granted to the Royal College of Surgeons of England is a great improvement on the Charter of 1813, and although it does not contain all the provisions for which this Association has contended, yet it firmly establishes the representative system in the constitution of the governing bodies of the profession, and thus has given satisfaction to a large body of our members.

The College of Physicians has also been endeavouring to obtain a Charter, and the draft that has been submitted to the Secretary of State by that learned body is conceived in a liberal spirit; and although your Council cannot commit themselves to all its details, yet they have no hesitation in stating, that should this Charter be granted to the College of Physicians, it will very materially improve the medical polity of the kingdom.

Seeing the probability that the College of Physicians and College of Surgeons would ere long obtain new Charters, your Council have been anxiously endeavouring to submit to the Legislature a comprehensive measure, which might settle, on liberal principles, the medical polity of the profession. Being assured by Sir George Grey, the late Home Secretary, that he would give a favourable consideration to any Bill for improving the medical profession which should receive general support, a Committee was formed of members of the Association, at the latter end of last year, whose object was to frame a Bill in conformity with the principles so long advocated by the Society. This attempt was so far successful, that in the early part of this year the Draft Bill was submitted to the Central Council, who, after a careful consideration of its clauses, were of opinion that it fairly represented the opinions so long promulgated and so undeviatingly maintained by this Association in their memorials to the Secretary of State, and in their petitions to the Houses of Parliament. They therefore resolved upon taking the opinion of the members at large on this Draft Bill, and in order to do so they requested the district Branches to meet and to consider its provisions. Meetings of most of the Branches were consequently summoned, and the result has been that the Bill has been enthusiastically received by the great body of the profession in the provinces, and a very considerable majority have declared themselves in favour of an attempt to pass it through Parliament. Nor has the opinion in favour of the Bill been confined to the members of the Association; many societies not connected with this body have met, and have passed unanimous resolutions in favour of the Bill. So that this Association has at length succeeded in framing a Bill in accordance with the feelings and wishes of a large majority of the profession in the provinces. It would take up too much time, and indeed it is unnecessary, for your Council to enter into a consideration of this Bill, as it has already been so thoroughly canvassed. Had Sir George Grey remained in office, he might have passed the Bill during the present Session of Parliament, but the change in the Government has necessarily retarded our progress. It is, however, satisfactory to state, that Mr. Walpole, the present Home Secretary, has expressed his readiness to give his attention to the Bill so soon as the state of public affairs will permit him to do so.

In the present state of affairs, your Council consider the better course to pursue will be for the Association, at this Anniversary Meeting, to come to some general resolution approving of the Bill, and then to refer it to a Committee, who should be empowered to negotiate with the Government and with the medical corporations, and to make such modifications in the Bill as circumstances call for. As expenses are likely to be incurred in prosecuting this matter, the Committee should be allowed a sum, not exceeding £200, for necessary expenses.

Reports of Committees.

The Committee on Medical Ethics, the Income-Tax Committee, and the Committee on Irregular Practice, will be severally called upon for a Report.

Benevolent Fund.

The Benevolent Fund has progressed steadily, and its Funds have gradually augmented; but this increase of income has not been commensurate with the overwhelming tide of misfortunes it has been called upon to relieve.

Conclusion.

Thus have your Council endeavoured to indicate the state and condition of our Noble Association, and they call upon all zealously to co-operate in the great work which lies before us. During the twenty years the Society has existed, many important objects have engaged its attention, and willing labourers have been found to aid in the task. Nevertheless all our congratulations must be mingled with the regret that so much has been left to be accomplished. After years of struggle and of difficulty, we seem at length approaching the time when medical polity will be placed on a more enlightened basis, and it is so far gratifying to reflect, that the principles of medical legislation, which, years ago, were originally promulgated and advocated by this Association, and which then appeared all but impracticable, are now become generally popular, are advocated by a large majority of the profession, and will, no doubt, ultimately be adopted by the Imperial Legislature.

We have much, then, to encourage us to pursue our course. Let not difficulties deter us,—let not slothfulness or indifference paralyze us. We are all brethren working for one common cause—the cause of humanity, and our labour is the labour of love.

Notices of Motion for the Oxford Meeting, 1852.

Dr. Tunstall, of Bath, gives notice that he will propose the following addition to Rule 14 of the Laws of the Association:—After the words *General Council*, to add,—“That every Member of the General Council shall be an *ex-officio* Member of the Council of the Branch within whose limits he shall reside.”

Dr. Cowan, of Reading, gives notice that he will move,—“That the *Provincial Medical and Surgical Journal* be published weekly, and that it be Edited and published in London,”

Mr. Bree, of Stowmarket, gave notice at the Brighton meeting that he should bring forward a motion for establishing a prize to be called the “Jenner Prize.”

Dr. JENKS said the report which had just been read must be admitted to be, speaking in general terms, most satisfactory; he was not aware that there was anything in it which could lead to any discussion. The progress of the Society, and the flourishing state of its affairs, were subjects for congratulation, and he thought what

had been said in the body of the report relative to the progress of medical legislation, was very satisfactory. He believed the Bill which had been recently submitted to Parliament, would form the basis for useful legislation affecting the medical profession. Entertaining these views, he should move that the report now read should be adopted and printed.

Mr. SODEN seconded the motion.

Dr. COOKWORTHY (Plymouth) said, before the motion was adopted, he would call the attention of the meeting to a subject which he had mentioned at the Council meeting on the preceding night. He would observe, that what he was about to move, was not intended so much as an amendment as an *addendum* to the report. It was not his intention to elaborate, but he might premise by saying, that though he was far from disparaging the London College of Physicians in what they had done, he thought that any incorporated society, or even the Government of the country, should not impose restrictions or expense on any parties whatever, more than were needful or called for. It appeared to him that all Extra Licentiates of the Royal College of Physicians in London should be admitted members without any charge whatever. He further thought that provincial physicians, being Fellows of the Royal College of Edinburgh, should be admitted *ad eundem* on payment of a small fee for registration; and that all British physicians who had passed and taken a degree in any of the Universities should be admitted on payment of a small sum, seeing they had already paid a stamp duty on taking their degrees. He thought that as members of a liberal profession, and subjects of a free country, they had a right to claim from the Legislature that they should be admitted to that College on simply paying what was necessary, and no more. (Hear, hear, and applause.) So far as his influence with members of the House of Commons extended, he should use it to impede the proposed Charter, unless some provision to the effect he had stated were made in it. He thought they ought to appoint a committee of gentlemen belonging to the three classes he had named to communicate with the Royal College of Physicians upon the subject, as he was disposed to trust to the liberality of that distinguished College that it would grant what was asked. Another proposition he had to submit was, that when admitted to that College they ought to take rank according to their order, or the date of their degree. There were many men practising pharmacy in virtue of a licence from the Royal College of Physicians, and it was a most anomalous thing that they should take rank before the older members of the profession who had graduated long before. (Hear, hear, and applause.) It did appear a little *outré* that, if they were members of a College, they should take rank below surgeons. He then read the following resolution, which embodied his views on the subject, and moved that it be added to the paragraph in the Report having reference to Medical Reform:—“That this Association, fully admitting the propriety of uniting under the dominion of the Royal College of Physicians in London all Physicians, Graduates of Universities, practising in

England and Wales, and acknowledging the liberality of the proposed charter, are notwithstanding of opinion that the fees therein named to be paid on admission are unnecessarily large. The Association would also urge upon the College that their own Extra Licentiates should be admitted members without further payment; that many of the provincial physicians, being Fellows of the Royal College of Edinburgh, should be admitted *ad eundem* on payment of a small fee for registration only, and that Graduates of British Universities, actually practising as physicians, should also be admitted to become members of the Royal College of Physicians on payment of a smaller sum than that named at present in the Draft Charter, they having already paid a stamp duty on taking their degrees. The Association would also suggest, that the Graduates to be thus admitted members of the Royal College of Physicians of London should take order according to the dates of their respective degrees."

Dr. TUNSTALL (Bath) in seconding the motion, contended for the right of all properly-educated and duly-qualified British medical practitioners to be so admitted. He described the fees intended to be imposed for admission to membership as excessive, and objected most strongly to the proposed stamp-duty of fifteen guineas, urging that, as graduates had already paid the stamp-duty on their diplomas, it would be an act of injustice to tax them again. (Hear, hear.) In taking the course Dr. Cookworthy and he were pursuing, he thought the Association would feel they were actuated by the best motives for the welfare of the profession generally.

The PRESIDENT observed, that he understood Dr. Cookworthy did not propose his resolution as an amendment, but merely as an addition to the report.

Dr. COOKWORTHY assented.

Sir CHARLES HASTINGS said that, although agreeing in some particulars with Dr. Cookworthy, he must object to the proposed addition being made to the report. He thought it should be brought forward as a substantive motion. It would be found most inconvenient if they adopted the other course. The paper just read had been drawn up and deliberately agreed to by the Council; it was now presented, and should be received. The matter in question should have been mentioned to them at their meeting on the previous night, when, if approved of, the required addition could have been made.

Dr. COOKWORTHY contended that it was competent for the meeting to alter or amend the report in question.

Sir CHARLES HASTINGS said, if such were done, it would be the report of the Meeting, and not of the Council. He would suggest the desirability of appointing a Committee, to whom the consideration of the matter might be referred. (Hear, hear.)

Dr. COOKWORTHY felt so much interested in this matter, that he had come some hundred miles in order to watch over the interests of the provincial physicians. He was indifferent as to whether his resolutions were put in the form of an amendment, an addition, or a separate resolution; all he wanted was, that the point

involved in them should have the sanction of that body. He must say, that he could not agree with the dictum of Sir Charles Hastings, that a document of this nature could not be amended.

Dr. FORBES thought Sir Charles Hastings was right in point of form.

After some discussion it was agreed, on the motion of Dr. Cormack, seconded by Mr. Hunt, that the report should be received.

This having been done, Dr. Cookworthy moved that the resolutions he had submitted should be added to the report in a place indicated.

Mr. NUNNELEY expressed himself of opinion that the report must be referred back to the Council if an alteration were required to be made in it, as they and not the meeting were the proper parties to make it. The meeting could only receive or reject the report, but could not add anything to or retract from it.

Dr. COOKWORTHY said he must protest against this doctrine. When he tried to bring the subject before the consideration of the Council on the previous evening he was told he ought properly to submit it to the general meeting; and now he was adopting the course recommended he was told he ought to have gone to the Council. He contended that the general body had a right to entertain the question of alteration or amendment.

The PRESIDENT said the question for the meeting seemed to be, whether the report should be adopted as it stood, or whether Dr. Cookworthy's resolutions should be incorporated in it. (Hear, hear.) He then read the paragraph in the report, to which the addition was to be made, and also the proposed *addendum*, whereupon

Dr. HEYGATE remarked that before the resolutions were put to the meeting he wished to ask one question, namely, whether the new charter of the College of Physicians obliged all practising members of the profession to join the College? because he and others might not think it quite so high an honour to become members as it was imagined to be. He should like to know if there was or was not a compulsory obligation imposed, as that would make all the difference?

Dr. FORBES said the Charter contained nothing compulsory regarding the subject referred to; but an Act of Parliament was sought to be obtained which proposed to make it compulsory. If the College of Physicians tried to get such an Act passed, then would be the time to oppose it.

Dr. TUNSTALL thought they ought not to wait; but that they were bound to ask the members of that Association to protect the interests of the profession generally. They should obtain an expression of their opinion before another year was permitted to elapse.

After some conversation on matters of detail it was determined that the resolutions proposed by Dr. Cookworthy should be read over, and submitted separately for the approval or disapproval of the meeting. The President accordingly read and put the first, viz.,—"That the fees required on admission to membership were excessively large," which was affirmed almost unani-

mously. He then treated the second in like manner, when

Mr. BAILEY objected to the course pursued, and thought it would be simplifying the business if the report were adopted, and the matter under consideration made the subject of a separate motion.

Various members having severally expressed their sentiments amidst some confusion,

Mr. NUNNELEY said that as many members, owing to their not being in possession of correct information as to the amount of fees proposed to be required from the Extra Licentiates, did not feel competent to vote on the point submitted to them, he would beg leave to move, as an amendment, "That a Committee be appointed to watch over the interests of the provincial physicians, to whose consideration the resolutions of Dr. Cookworthy should be referred."

Mr. MARTIN seconded the amendment.

Dr. COOKWORTHY considered that the appointment of a Committee would be idle; and would only have the effect of getting rid of the question.

Dr. HALL thought the Association ought to have a pledge that the action of the Act of Parliament should not be retrospective.

The amendment having been put from the chair, was declared carried.

Sir CHARLES HASTINGS bore testimony to the liberal spirit evinced by the members of the College of Physicians towards the profession generally in the preparation of the new Charter.

Dr. COOKWORTHY having been induced to consent to the reference of his resolutions to a Committee, and to act as a member of it, on the motion of Dr. TUNSTALL it was ordered that such Committee do present their report next morning (Thursday.)

The original motion for the adoption of the report was then put, and carried unanimously.

Sir CHARLES HASTINGS said he had a very pleasing duty to fulfil. All those who were present at the meeting last year, must have felt extreme satisfaction, and those who were not so present, on reading the report in the *Journal*, must have experienced a similar feeling at the urbanity and ability with which the proceedings were conducted by the late worthy President, Dr. Jenks. (Cheers.) That gentleman had come a great distance in order to be present with them to-day, and to testify his good feeling towards their Association. He was sure every gentleman present would respond most cordially to the motion he was about to propose,—“That the thanks of this meeting be given to Dr. Jenks, the retiring President; and that his name be placed (as customary) on the list of Vice-Presidents.”

Dr. FORBES seconded the motion, which was carried unanimously.

Dr. JENKS, in acknowledging the vote of thanks, expressed the gratification he experienced from finding that his exertions had given satisfaction.

On the motion of Sir CHARLES HASTINGS, Messrs. Bartrum, Carter, and Nunneley, were appointed to audit the accounts of the Association.

Dr. BOND (Cambridge) moved,—“That the thanks of this meeting be given to the Council of the Association for their services during the past year, and that they be requested to continue their services, with the following additional members:—

Dr. Cormack	Putney
Mr. Gillett	Taunton
Mr. Randolph	Milverton
Dr. BurrIDGE	Taunton
Dr. Howell	Swansea
Mr. Bottomley	Croydon
Dr. Radclyffe Hall . .	Torquay
Mr. Bayley	Chippenham
Dr. Barclay	Leicester
Dr. Hitchman	Mickleover, Derbyshire
Mr. Reid	Canterbury
Mr. Alford	Taunton
Mr. Bridge	Wellington, Somerset."

Mr. PROPERT seconded the motion, and in so doing bore testimony to the zeal with which they discharged their duties.—Motion carried.

PUBLICATIONS OF THE ASSOCIATION.

Dr. COWAN (Reading) said he was quite sure that none present would look upon him in any other light, as to the course he was about to take, than as one who felt a deep interest in the welfare of the Association; certain it was he had no individual interests to serve or ends to gratify. It was not his desire to find fault, or, as it was termed, "pick holes," in the character of any one whatever; but he must say that if they looked back to the past, however much cause they might have for rejoicing at what had been done, there was still much to occasion anxious solicitude. The number of subscribing members had been gradually diminishing of late years. In 1845-6-7 there were more than 1800; while at the present time it was doubtful whether 1600 could be found on the list. He felt that the cause of this was to be found in the fact of the Association not having carried out the objects it proposed to accomplish. The *Journal* had never been what it ought to be—an efficient organ of the Association; and, conducted on the plan it had hitherto been, never would be. He was aware that in moving an alteration in its mode of conduct, and change of place of publication, he should be met by the objection that by making such a change they should be losing their provinciality. Though he should be the last to do this, he yet must say that provinciality was not all to them as an Association; on the contrary, they wished to identify themselves with all their brethren of the profession. They did not wish to exclude from their ranks their metropolitan brethren; but to blend all in one body, united for the furtherance and protection of their mutual interests. The Association, they were informed, numbered 1,600 members; but looking at the number of medical practitioners in the kingdom, and the important objects the Association was established to accomplish, they ought to count their members by thousands. (Hear, hear.) By removing the publishing and editing

of the *Journal* to London, and making it a true exponent of the views and feelings of the Association, and a standard of reference to the medical profession generally, he considered they would soon be enabled to realise this, and induce almost every member of the profession to join their ranks. The removal of the publication would not alter its feature of provinciality; but its continuance at Worcester would be only perpetuating provincial weakness and provincial defects. The Association possessed a claim upon the profession possessed by none other; and could it be said that if it had been managed judiciously they should not number, after twenty years' existence, more than 1,600 members, and after holding Anniversaries in all parts of England? (Hear, hear.) He held that they were in a position to bring out a better periodical than any merely private speculator, if their energies and funds were rightly directed. Dr. Cowan went into the question of the relative expense in bringing out the *Journal* weekly and fortnightly, and pointed out that by the course he indicated the Association might bring out a first-rate professional literary weekly publication for about the same or rather a less sum than they were now paying for the bringing out fortnightly a journal which did not give satisfaction. He observed that in the whole range of his experience he had never found one who had expressed himself satisfied with the *Journal*. In making these remarks he did not wish to be understood as personally reflecting on the Editors; he was speaking for the welfare of the Association, which could not be promoted by the present publication. What he would recommend was this,—have the management of the *Journal* centralised in London; let there be a London Editor, who, it would be seen at once, would possess advantages from his position which a provincial Editor could not have; and make it the *best* medical periodical in the kingdom—one that would be read and referred to by all, instead of being a defective publication, as at present, not read but by a fraction of the professional body. The Association ought to give to its members a journal which should supply them with all they required in periodical literature. They might rely upon it, the Association would never improve unless the *Journal* was improved; unless they could come before the public with something worth their acceptance and support they would never experience it. It was his conviction that the Association was dependent for its continuance on the energy and zeal of a few of its members, deprived of which it would tumble to pieces. This was, however, a state in which it was not desirable to remain. They might, perhaps, linger on from year to year, and might have some slight accession to their numbers, but they would never accomplish the objects for which the Association was established. They must by an effort seek to effect an improvement in periodical medical literature. The individuals with whom he acted, and who shared his views in this matter, had no selfish objects to gratify; they sought only the good of the whole body of members, and he was ready to aid the carrying into effect the

proposed changes to the utmost of his power. His plan for the future management of the *Journal* would be, to centralise the labour of Editorship in one individual, (for it was impossible for two men, and these, too, separated by long distance, to work together,) and print and publish in the metropolis. Some might object that this would do away with the supervision of the Central Council. The contrary of this would be the case. The influence of the Council could be equally well exerted at London as at Worcester. What would be effected principally by the change, would be a complete revolution in the literary department. He thought no valid objection could be urged against the plan, either on the ground of want of provinciality, or of defect of management. Though he should be the last to wish to differ in opinion from any individual, yet upon this subject he felt so strongly, from a deep conviction of its importance, that even if they were all opposed to him, he would advocate it. As matters now were, if he for one endeavoured to induce persons to take in the *Journal*, what sort of answer did he receive to his application? why, a contemptuous "I do not want your journal;" but if the plan he recommended were adopted, and they had an efficient journal, would not the aspect of affairs be altered?—would not friends join them in thousands? This accession would not be gained by excitement,—it would not be by going to Brighton, or Oxford, or any other place, but by an appeal to the reason and by conviction. From information he had received, and calculations made, he found that he could farm their journal out in London, and publish a first-rate weekly one, for £1200 a-year, in which they might calculate on having £100 for advertisements annually, and a very large accession of subscribers. Surely, then, this would be better than staying where they were. If any gentleman, however, had any reason for not wishing the improvement of the *Journal*, why let him state it. He had, himself, much more to say upon the subject, but he would abstain from remarking further, and would conclude by moving, "That in future the *Journal* be edited and published in London, and that it be published weekly, instead of fortnightly, as at present." (Dr. Cowan resumed his seat amidst much applause.)

Dr. WOODHOUSE seconded the motion.

Dr. ROBERTSON wished only to offer a very few remarks in reply to the eloquent observations of the previous speaker (Dr. Cowan.) He might observe, he had listened with great pleasure to a good deal of what he had said, but he could not agree with him in his conclusions. With respect to removing the publication of the *Journal* to London, that experiment had been tried already and failed. It was tried in 1844 when he was President, and Dr. Streeten and Dr. Hennis Green had the conduct of it, who experienced an endless amount of trouble. It by no means followed, that because London was the centre of unity, it must be perforce the centre of success. He was sure they must all remember that the publication he referred to, with all the advantages derivable from having a metropolitan Editor, possessing all

the means of obtaining information, &c., failed entirely as a commercial speculation. The reason why it failed as such was the competition which it had to encounter. Some professional men took in the *Lancet*, and some other medical periodicals, and so the *Journal* did not derive that amount of support which was necessary to ensure its success. He was therefore disposed to object to the removal of its publication to London, partly because such had been tried already, and partly because he thought the Association would lose by adopting such a course the healthy supervision of the Council, and particularly that of the founder of the Association, Sir Charles Hastings. (Hear, hear.) He was content with the *Journal* as at present managed, but he thought if all the members of the Association were only to work well—do their duty, and put their shoulders to the wheel, the *Journal* might be made better than it was. He must confess, however, that he did not think the mere atmosphere of London would effect so beneficial a change as was supposed.

Dr. HEYGATE considered that without some more substantial reasons than those which had been adduced by Dr. Cowan, he did not see what good would result from the removal sought for. He might remark, that in his own neighbourhood the profession were all satisfied with the *Journal* as at present conducted. Where, he would ask, did they see a better publication of the kind? Let them only look at the articles. He, for one, thought they would lose a great deal by transferring the publication to London, and could not see any corresponding benefit likely to be derivable therefrom. After all, and notwithstanding the data supplied by Dr. Cowan, the change would be but a matter of commercial speculation. (Hear, hear.)

Mr. WALSH said he did not rise so much as an Editor of the *Journal*, as a member of the Council, to say a few words respecting the present motion. He fully concurred with Dr. Cowan in wishing to improve the *Journal* in every possible way. He agreed with him that there existed room for improvement, and improvements had been pointed out by him to the Council, but they had not been carried out, partly in consequence of the regulations of the Association not admitting of it, and partly for want of funds. He still thought that it was merely a question of expenditure whether they might not have the best medical journal in the kingdom. (Hear, hear.) He must, however, challenge Dr. Cowan to come forward and prove his figures. He maintained that it was impossible simply to print a weekly journal for a less sum than that specified by Dr. Cowan, without including the Editor's salary or publisher's profits. It would take the whole sum. He was ready to show by evidence from Manchester, Birmingham, and other large towns, that such a publication could not be printed for a less sum than that fixed by Dr. Cowan. While admitting, therefore, that the *Journal* was capable of improvements, he thought he was justified in calling upon Dr. Cowan to prove the correctness of his calculations. (Hear.)

Dr. EDWARDS as an old member of the Association, and one who felt interested in its well-

being, must say that in his opinion, so long as the Editorship of the *Journal* was divided, and shared by two individuals, that publication would not be, as it should, the efficient organ of the Association. At present it was, in his opinion, having a damaging effect. He was aware that he was here touching on delicate ground, and he would say that there were no men for whom he entertained more regard than for the present Editors. He did not wish his observations to be considered as conveying any personal reflection on them, but in the *Journal* as now managed he saw what would eventually swamp the Association. He would yield to no member in zealous effort to enlarge the boundaries of the Institution; but when asking his medical friends in Liverpool, Chester, and North Wales, to join it, and also subscribe to the *Journal*, he had been met with the question,—“What have you got to show us in return; show us a *quid pro quo*.” He knew only two medical men in his neighbourhood who took in the *Journal*, without at the same time also taking in the *Lancet* and *London Medical Journal*, and its pages were seldom cut. The fault of this, he maintained, did not lie with the subscribers. Let them only look at the next number of the *London Medical Journal*, and at the names of the writers therein. If they were to ask any of these gentlemen to contribute to the journal of the Provincial Medical and Surgical Association, the reply would be,—“We are not going to bury our articles in that catacomb.” (Laughter, and “Oh.”) These gentlemen were well aware, that among the great body of the profession this journal was not looked at, nor read. He apologised for the warmth of his observations, but he yielded to no one in wishing the welfare of the Association, in which he was sorry to see the seed of decay instead of the germ of success. He did not, as he had previously said, wish to say anything against the present Editors of the *Journal*, with whom he sincerely sympathised. They were tied hand and foot, as was evidenced by their last leaders, and precluded from bringing out that high-spirited periodical which the profession generally required, and which was necessary in order to enable the Association to maintain its position, and effect the objects for which it was established. Dr. Edwards concluded by expressing himself warmly in favour of the proposed change of publication and management of the *Journal*, and intimating that his support would be willingly rendered to aid in carrying it out.

It being now one o'clock, Mr. NUNNELEY moved an adjournment, which was at once agreed to.

CONFERRING OF HONORARY DEGREES.

At two o'clock the VICE-CHANCELLOR held a Convocation in the Sheldonian Theatre, and conferred the Honorary Degree of D.C.L. upon the following members of the Association, who were presented by Dr. Phillimore:—Sir Charles Hastings, Dr. John Forbes, and Dr. John Conolly. This was understood to be intended as evincing the esteem entertained for the Association by the University, in thus bestowing upon three of its leading members the highest honours in its power to

bestow. Dr. Burrows and Dr. Ranking were also admitted, *ad eundem*.

SECOND GENERAL MEETING.

THE ADJOURNED DEBATE.

On the re-assembling of the members in the Convocation House at three o'clock, the debate on the motion of Dr. Cowan was resumed.

Mr. NUNNELEY (Leeds) said he was one of those who thought the *Journal* had improved under the present Editors, but he felt sure neither of those gentlemen would feel offended at him if he said he thought it might be still better conducted; and that it was capable of improvement had been admitted by one of the Editors. He was of opinion that it would be better to appoint a Committee to investigate the question in all its bearings; for although they might be satisfied with the *Journal*, there was no reason why it might not be so much improved as to enable members to dispense with taking in other medical publications. He was aware it might be urged, that the fault mainly rested with the members themselves, as they did not send in contributions to the *Journal*. He thought there ought to be but one Editor, who should be responsible for what appeared in it, but this was a point for the decision of the Committee; and it would also be a question for them to consider whether the "Transactions" and the *Journal* might not be blended in one. What was required by the members was, a periodical which should give them not only the ordinary medical news of the day, but the best scientific information, so as to keep pace with the progress of scientific improvement, and to possess an interest for others as well as the mere professional readers. That such was not effected by the *Journal* at present was, he thought, pretty well evinced by the fact, that only £21 had been received from the public for the sale of both *Journal* and "Transactions" for the year. If something were not done, they might anticipate a loss of their members. In York there were seven members of the Association, and some of them spoke of seceding; he should, therefore, move as an amendment to Dr. Cowan's motion,— "That a Committee be appointed, with full power to consider such changes as might be necessary in the management of the *Journal*, and to carry the same into effect in 1853." Mr. Nunneley added a list of gentlemen he wished to constitute such Committee.

Dr. ROBERTSON seconded the amendment.

Dr. TUNSTALL thought that Dr. Cowan had brought forward such a proper proposal that it ought at once to be affirmed. He expressed himself as not averse to the appointment of a Committee; but previous to doing so, he thought the meeting should come to a decision, aye or no, on the points submitted to its consideration. He was in favour of having but one responsible Editor, instead of having two as at present, who were shackled in their action, and strongly reminded him of Macheath dancing in fetters. (A laugh.) The speaker was proceeding to allude to some personal matter between himself and one of the

Editors (Mr. Walsh), when he was met by loud cries of "Question."

Mr. LORD (Hampstead) spoke in rather strong terms regarding the *Journal*, which he described as an *effete* publication, "stale, flat, and unprofitable;" and which he said he understood many of the members did not read at all, but left it on their shelves with the leaves uncut. He exhorted the meeting to adjudicate at once on the question whether they would continue to have a journal supplied to them, backward in intelligence and torpid in delivery, or such an efficient organ as that proposed by Dr. Cowan.

Mr. CROMPTON (Manchester) observed, that if his recommendation had been acted on in 1849, they would not be placed as they were at present with regard to the *Journal*. He could speak as to the opinions of the medical profession in the north being that it was a very unsatisfactory publication. He found that the number of subscribers was 1,927 in 1845 (the greatest number); since which time they had been gradually falling off. He wished to ask Mr. Walsh if he could inform them how many copies of each publication of the *Journal* had been struck off year by year during the time he had been connected with its management.

Mr. WALSH stated that he believed the present number was 1,675; it had been down as low as 1,550. He believed that the number of *paying* members of the Association was greater now than it had ever been. In pursuance of a resolution adopted by the Association with respect to defaulters, a number had been struck off the list of members, some of whom were seven, eight, or nine years in arrear, and who, though they swelled the list, were a dead loss to the Association. Since he had been engaged in the Editorship the number of copies had gone up from 1,500 to 1,675, and the advertisements had doubled. (Loud cries of "Hear, hear.")

Mr. CROMPTON having observed upon the singularity of the circumstance that although more members were stated to be now on the books, yet that about 1,650 members only paid £1,350, and desired some explanation,

The SECRETARY read various explanatory extracts from the accounts, and in the course of conversation that followed, Mr. CROMPTON hastily observed that he did not believe there were so many members on the list as represented; but being called to order by Sir Charles Hastings, he retracted the assertion.

Dr. RANKING could have wished that politeness had been combined with eloquence by some who had addressed the meeting. (Laughter.) He might observe with respect to the number of members that some members had died, others had been struck off because they were in arrears; and it should be remembered, also, that in consequence of the depression in the agricultural districts medical gentlemen residing therein had been compelled to decline subscribing to the *Journal*, the *Lancet*, and the quarterly medical publications. He knew it to be so in Norfolk and Suffolk, where they were obliged to be careful in the disposal of every guinea. As to what had been said about the *Journal* being allowed to lie on the shelves

or tables of members uncut, he thought much stress need not be laid on that; for how often did they see valuable works similarly treated. He had himself seen a translation of Louis "On Phthisis," by Dr. Cowan lying by with the leaves uncut. (Laughter.) He would only remark, in conclusion, as the management of the *Journal* was complained of, that if he was in the way he should be happy to resign the post of Editor. ("No, no.")

Sir CHARLES HASTINGS said it was clear from the Secretary's statement that the number of paying members was greater now than it had been for some years. In the course of the past year they had formed two new branches, which had brought in an accession of a hundred members; and he thought if they continued to go on steadily they should increase still more. (Applause.) He must say, if gentlemen were prepared to have a weekly publication of the *Journal* they must give up the "Transactions." During the whole course of the twenty years the Association had been established the expenditure had been kept within the income; but he verily believed if they engaged in the publication proposed their expenses would be so much increased as very shortly to involve the Association in bankruptcy. (Hear, hear.) He would willingly vote for the appointment of a Committee, because he thought inquiry would be productive of good.

Dr. COWAN, in reply, stated that Mr. Walsh had challenged him to prove his figures respecting the cost of publishing the *Journal* in London. He gave it to the meeting on the word of a London printer, whom he had consulted on the subject, that the *Journal* could be brought out weekly, with better type and better arrangements altogether, for £1140 a-year, this exclusive of editorship; but a person could be found, who would devote himself wholly to the performance of the duty for the salary now paid to the joint-editors (£250 per annum.) So that speaking in round numbers, for an outlay of £1,400 they would have a first-rate weekly periodical, in place of their present one, and he could not doubt that the change would be productive of good. It was not intended to compete with the London journals, but simply to supply the members of the Association with a sound literary periodical, every way suited to their requirements, and which should advocate and advance the interests of the profession generally. Dr. Cowan met the objections which had been urged in the course of discussion, against the removal of the publication as destructive alike of the provincial character of the *Journal* and of the influence of the Central Council; and in conclusion remarked, that if the meeting decided in favour of his motion, he was willing to take the Committee which had been already named, in order to carry out the details.

Mr. WALSH complained, that in reply to his challenges of proof by figures, Dr. Cowan had receded from his first statement as to total costs of publication, and now stated that the £1200 (in round numbers) he at first mentioned did not include the cost of Editorship. He (Mr. W.) said that he was ready to prove from documents which he held in his hand, that the cost of print-

ing a journal of the present size, including only paper, stamps, journeymens' wages, and merely four per cent. upon the cost of machinery would amount to £1118. This did not include any charge for printer's or publisher's profits, and was founded upon data obtained from the *Manchester Times* Office and from Birmingham, where printing was done as well and much cheaper than in London. He believed, therefore, that when Dr. Cowan came to the real working of the matter, he would find himself sadly mistaken.. (Spoke, spoke.)

Dr. COWAN replied that he was quite right in his calculations, and that for £1400 a year he could do all that was required.

Mr. WALSH expressed himself as doubtful that such a publication as the one contemplated could be got out for the money.

Dr. COWAN: All I know is, that I have an offer from a London printer to do so.

The PRESIDENT then put the amendment, in the usual way, by a show of hands, but the numbers appeared to be so equally divided, that it was urged there should be a poll; an attempt was accordingly made to take one, but in consequence of the confusion which ensued, it proved unsuccessful. It was then suggested that those in favour of the amendment should sit on the left of the chair, and those opposing it on the right, and that the respective numbers should be counted by two tellers. A number of gentlemen who declined to vote either way retired to the adjoining room. The result was as follows:—

For the amendment	61
Against it	59
<hr/>	
Majority	2

The announcement of the numbers was received with much applause, and an exciting scene ensued, and in the midst of the confusion attendant on this, the President declared the *original motion (which had not been formally put to the meeting)* carried.

Dr. EVES (Cheltenham) wished to ask whether it would be a seemly proceeding, in a Society like theirs, to allow so important a change to be effected on the strength of so small a majority? (Laughter, and a cry of "The House of Commons.") All the members were equally anxious to benefit the Association; and he did think, when opinion was so nearly balanced as the recent division had shown, they ought not to proceed until they had appealed to the whole body, and ascertained their feeling respecting it. (Hear, and "chair.")

Dr. COWAN having again signified his willingness to accept the Committee previously nominated by Mr. Nunneley, moved a resolution for its appointment, with an instruction to superintend the future publication of the *Journal* in London. On the list being read over by the President, the greater portion of those nominated withdrew their names immediately. After some conversation, a Committee consisting of eight or nine gentlemen was *understood* to be appointed, though the proceedings were here extremely confused, and the appointment, if made at all, was done in a most irregular manner.

In reply to a question from Mr. Walsh, as to the position the Editors were placed in by the recent vote, Dr. COWAN said he wished it to be understood that no alteration would be made in the present arrangements until January, 1853.

Some members expressed a hope that the Editors would consent to continue their services in the meanwhile.

Dr. RANKING at once declined, and resigned his post as one of the Editors.

Mr. WALSH said, that although his feelings prompted him to follow the example of his colleague, yet, as he had always taken a warm interest in the prosperity of the *Journal*, and feared it might be injured by the sudden withdrawal of both Editors, he would lay aside his feelings, and go on with its conduct for the present as well as he could. (Much cheering.)

INCOME TAX COMMITTEE'S REPORT.

Dr. SMITH (Cheltenham) read the following report of the Income Tax Committee:—

Report on the Property and Income-Tax, as affecting the Medical Profession.

"The Committee appointed at the last Anniversary to consider and devise means for relieving the medical profession from their unequal share of the present Property and Income Tax, beg to report that they have lost no opportunity of bringing the subject before Her Majesty's Government and influential Members of Parliament. The recent political changes have, however, prevented their exertions from producing as yet any practical result. They have the authority of Mr. Hume, Chairman of the Income-Tax Committee of the House of Commons, for stating that from the information which he has obtained, there can be no difficulty in adopting a more just mode of rating professional incomes. Owing to the immense amount of business before the Chancellor of the Exchequer, and to the ascertained fact that he was determined to recommend the continuance of the Income-Tax in its present form for another year, your Committee have not sought a conference with him. The number of witnesses which have been already heard against the measure before the Income-Tax Committee of the House of Commons have hitherto prevented your Committee from tendering their evidence; but upon the assembling of the new Parliament, they expect to appear before a Committee to be appointed for completing the inquiry. From the amount of gross injustice which this impost has been proved to have produced, your Committee entertain a strong hope that it will, in the next Session of Parliament, either be materially modified or totally repealed; but still they earnestly urge upon every medical practitioner the necessity of treating this question, not as a general, but as an individual one.

"Your Committee would suggest to the members of the Association the propriety of petitioning both Houses of the Legislature against the continuance of this impost. And they would moreover advise this meeting, and also the district branches, to nominate gentlemen to wait upon the individual members of the House of Commons resident within their district.

"Should these suggestions be carried out with energy and spirit, your Committee confidently believe that they will have the pleasing duty of announcing at your next Anniversary, that this odious, inquisitorial, and unjust tax has been expunged from the Statute Book." (General cries of "Hear.")

The Report was received and adopted.

IRREGULAR PRACTICE.

Dr. CORMACK read the report of the Committee on Irregular Practice, and in so doing congratulated the Association that there were no longer any respectable members of the profession who would maintain intercourse with homœopathic professors; in bringing about which improved state of things the Association had been mainly instrumental. (Applause.) The report was as follows:—

"The Committee on Irregular Practice, have attentively considered the subject confided to them by the Anniversary Meeting of the Association at Brighton in August last.

"In consequence of the limits assigned to the Committee they have not considered themselves authorized to enter upon any of the other forms of Irregular Practice, although they regard them equally with Homœopathy as opposed to the sense of the profession.

"The Committee have endeavoured to frame the bye-laws which they now propose for adoption, in such a way, as on the one hand, to maintain a high tone of professional honour in the Association; and on the other, to guard against the risk of accused parties being expelled from insufficient evidence, or so long as there is ground to believe that they have repented of their conduct, and are prepared to promise not to repeat it.

"The following is a draught of the bye-laws which the Committee request the Central Council to submit to the consideration of the anniversary meeting to be held at Oxford:—

- "1. Candidates for admission to the Provincial Medical and Surgical Association, shall be required to state, in writing, to the Members proposing them, that they neither are, nor intend to become, professors or practitioners of Homœopathy
- "2. That when any member is convicted by the Central Council, or by any of the Local Councils, of publicly professing homœopathy, of practising homœopathy, or of holding professional intercourse with a homœopathic professor or practitioner, this conviction, along with the necessary proofs of its justice, shall be officially reported by the Secretary of the Central Council, or by the Secretary of any of the Local Councils, to the next ensuing anniversary meeting of the Association; that it shall then be competent for the meeting, provided there be a concurring majority of two-thirds of those present, to direct the President in the Chair to erase the name of such convicted member at once from the roll of members; but that it shall likewise be competent for the meeting by a simple majority, either honourably to acquit the accused, or to accept from him, in entire satisfaction for his conduct, an expression of regret, and a promise not to repeat it; or to postpone final judgment till the next anniversary meeting

JOHN ROSE CORMACK, M.D., London.
CHARLES COWAN, M.D., Reading.
CHARLES HASTINGS, M.D., Worcester.
JONAS MALDEN, M.D., Worcester.
W. H. RANKING, M.D., Norwich.
JAMES TUNSTALL, M.D., Bath.
C. J. B. WILLIAMS, M.D., London.

This Report was also received and adopted.

MEDICAL ETHICS.

Dr. GREENHILL being called on by the Chairman to read the report on Medical Ethics, said the Committee were sorry to say, that in consequence of the death of one of their members, and a difference of opinion which prevailed among the others, no report had been prepared.

NOTICE OF ALTERATION OF LAW.

Dr. TUNSTALL moved a resolution, having for its object, the alteration of rule 14, to the effect that every member of Council should be an *ex-officio* member of the Council of the Local Branch in the locality in which he might reside.

Dr. COOKWORTHY seconded the motion.

The proposed alteration was warmly opposed, as having a tendency to interfere with the present popular mode of election; and on the motion being put, only two hands were held up in its favour.

The meeting adjourned at five o'clock.

THE CONVERSAZIONE.

Dr. Acland (Radcliffe's Librarian) having very courteously proposed to receive the members of the Association in the Radcliffe Library, a very numerous party of gentlemen attended a conversazione in that splendid building, at half-past eight o'clock. The Library was brilliantly lighted up for the occasion, a splendid candelabrum, with numerous branches, being placed in the centre. Around the pedestal which supported it were ranged a variety of choice greenhouse plants. We should think there could not have been less than five hundred persons present, including the Vice-Chancellor, several heads of houses, the Mayor, and several Aldermen and Councillors of the city, and all the members of the Association who attended at the Anniversary. It would be impossible for us in our limited space to particularize the varied objects which were presented to the admiring gaze in every portion of this beautiful building, we may therefore briefly state, that besides the usual interesting ones there were several tables containing objects of much interest to the scientific, professional, and general observer. The pendulum experiment of Foucault, showing the rotation of the earth, excited great attention; as did also preparations for the microscope by Mr. F. Symonds and Mr. Topping; pathological and physiological preparations from Christ Church College Museum; and pathological and microscopical preparations by Lionel Beale, Esq., M.B. A variety of osteological specimens from Christ Church College Museum, and some exhibited by Mr. Flower, a professional gentleman, of London, were much admired; among these was a skeleton of the python, and also of a large crocodile, ten feet long, stated to be the finest specimen in England. N. S. Maskelyne, Esq., (reader in mineralogy,) had a table devoted to a display of daguerreotypes, demonstrating the improvements which have been effected in this wonderful invention. Among the articles of a practical character connected with the medical and surgical profession, Messrs. Weiss exhibited a selection of sur-

gical instruments, with the recent improvements; and Messrs. Sparks and Co., a large assortment of bandages, and kindred surgical apparatus, including the new patent elastic stockings, knee-caps, &c., &c. The achromatic microscopes and apparatus of Messrs. Smith and Beck, to whom the Council medal of the National Exhibition was awarded in 1851, attracted much observation; and the London Gutta Percha Company exhibited a choice collection of gutta percha manufactured articles from their works, showing the varied uses to which that substance is capable of being applied. Tea, coffee, and other refreshments were served in the galleries, the whole of the arrangements being most judiciously conducted, and a very agreeable evening was consequently enjoyed. We should not omit to notice that one of not the least attractive objects to the visitors was formed by the exhibition of two of the leaves of the gigantic water lily—the *Victoria regina*—with flower and seed vessels; these were placed near the staircase at the entrance, and we were given to understand had formed a part of the plant growing in the conservatory at the Botanical Gardens. The greenhouse plants, before mentioned, were also furnished from these gardens.

THIRD GENERAL MEETING.

THURSDAY, JULY 22.

A public Breakfast was provided this morning at half-past eight o'clock, at the Star Hotel, which was extremely well attended.

The Association again assembled in general meeting in the Convocation House, at twelve o'clock, when the President announced that in consequence of the length of time which had been occupied in the discussion relative to the publication of the *Journal* on the preceding day, the strictly routine matters only would be proceeded with.

CHARTER OF THE COLLEGE OF PHYSICIANS.

Dr. COOKWORTHY informed the meeting that the Committee appointed yesterday, to consider and report upon the subject of his proposed addition to the report of the Council, had unanimously adopted the following resolution, which he would with permission read:—

"That the Committee appointed yesterday to take into consideration the bearing of the proposed Charter of the College of Physicians of London on the Provincial Physicians of England and Wales, have met, and not feeling themselves in a position to present a detailed report, have unanimously resolved to invite all Provincial Physicians now in Oxford to meet this day at 5, p.m., in the Divinity Schools (permission having been obtained), and there to form a Committee authorized to put themselves in communication with their brethren, and with the London College of Physicians, with the view of making such suggestions as may appear necessary to protect the interests of the Provincial Physicians practising in England and Wales without compromising the welfare of the profession at large or the public good, the only proper end and object of legislative enactment.

"J. COOKWORTHY, M.D.,

"On behalf of the Committee.

"Oxford, 22nd July, 1852."

The report of the Committee was received and adopted.

MEDICAL REFORM.

Dr. ROBERTSON said he had been called upon to move a resolution relating to the Medical Reform Bill. The subject had been before the notice of the profession for a number of years, and they had had frequent opportunities of discussing it. He might observe that Mr. George Hastings, (son of Sir Charles,) barrister, who had been concerned in the drawing up and preparation of the Bill about to be submitted to Parliament respecting it, was in attendance to explain its leading provisions. The resolution was as follows:—

“That this Association consider that the Draft Bill for Medical Reform, which has been prepared by the Central Council, embodies the principles uniformly advocated by the Association, and that the Bill be referred to a Committee, who are hereby empowered to make such alterations and modifications in the Bill as to them may appear expedient, and also to negotiate with the Home Secretary, and with the Medical Corporations, with a view that such Bill, on the earliest opportunity, be presented to Parliament, in order to its passing into a law.”

Mr. CARTWRIGHT, in seconding the motion, said, it was important that a Committee should set to work actively to carry out the Draft Bill emanating from the Central Council; it was the more necessary, as there was reason to fear that the apathy of the profession on this long-debated question was so great, that when all differences were nearly adjusted, the final and crowning measure of the whole would be lost for want of energy. The Draft Bill (if not a perfect measure) had given much more universal satisfaction to the profession at large than any other measure submitted to it. It was unnecessary for him (Mr. Cartwright) to enter into details of the construction of the Bill, as that would be much more ably done by a talented barrister (Mr. George Hastings), who would fully explain the provisions of the Bill to the meeting. The construction of the Bill was simple, not interfering with any *strictly professional* corporations, and appointing such penalties only as were necessary to correct irregular practice. The Bill was based on the adoption of the two new Charters of the Colleges of Physicians and Surgeons, which were framed in a liberal spirit, and the latter of which has already come into operation, and tended much to heal those disputes which had existed between the College of Surgeons and their members. (Applause.) The governing body (in the present Bill) was to be formed by one-third of its members being appointed from the College of Physicians; one-third from the College of Surgeons; and one-third independently selected from the bulk of general practitioners by the Secretary of State; the Council would also receive weight and dignity from the addition of the Regius Professors of Oxford and Cambridge, and from the President of the Colleges of Physicians and Surgeons. It was his firm opinion, that a Council so selected from the *élite* of the profession, would carefully watch over the interests of the general practitioner, and would be found of much greater utility, more effective, and more agreeable to the profession, *than any third incorporation*. (Applause.) Mr. Cartwright would here appeal to those gentlemen

who had favoured the proposed third incorporation! As it was now clearly impossible to carry out the institution of a third incorporation, he suggested that the appointment of such an independent Medical Council as the Bill provided for, would form a neutral ground on which the members of the Institute of General Practitioners could unite with the promoters of this Bill, and provide effectually for what they were all deeply interested in, the improvement of the *status* of that hard-working and deserving class, the general practitioners of the country; he hoped the appeal he now made would end in some of the Institute gentlemen being now appointed on the Committee. The advantage of this would be, that, if by mutual concessions an understanding could be come to, they could approach the Colleges of Physicians and Surgeons as one body, united to obtain a Bill for the general benefit of the profession; it was already known that the College of Physicians approved of the measure; he hoped the College of Surgeons would listen favourably to their requirements; and such unanimity on all sides would greatly enhance the favourable opinion, which the Home Secretary was disposed to entertain of the measure; in fact, it had been stated, that if it could be presented to Mr. Walpole under such circumstances, it would be adopted as a Government measure. He would urge the Committee to push forward to such a consummation; and in the hope, that ere long, this long-agitated and most important measure would be honourably and satisfactorily arranged by legislative enactment, he would conclude by seconding the nomination of the Committee proposed by Dr. Robertson, to carry out the proposed Draft Bill of the Central Council. (Applause.)

Mr. G. HASTINGS (barrister,) then rose, and at considerable length explained the steps he had taken in the preparation of this measure, under the direction of the Committee of the Association. He observed that it was at first desired to include within the scope of its provisions Scotland and Ireland, but from the difficulties ascertained to exist, it had been deemed advisable to confine its action to England and Wales, as reciprocity of practice could only be secured by uniformity of education. It was his belief that had Sir George Grey remained in office, so impressed was that gentleman with the importance of the subject, a measure would have been passed by the late Government which would have proved acceptable to the profession generally, but the change of administration had prevented his doing so, and singularly unfortunate was it that such change occurred only a day before Sir George Grey would have taken up the Bill. After the formation of the present Ministry, he (Mr. Hastings) had an interview with Mr. Secretary Walpole, to whom (having the honour of a personal acquaintance) he explained his views more fully probably than under other circumstances he could have done, and Mr. Walpole assured him he would give the matter his best consideration, and that if a Bill should be laid before him which should have the support of the profession generally, he should feel it his duty to bring it before Parliament;

he (Mr. Hastings) consequently thought that they might expect ample justice at the hands of the Home Secretary. (Applause.) He had in the course of his proceedings endeavoured to ascertain the feeling of the House of Commons on the subject, and with that view had asked the opinion of several influential members, the result of such inquiry being the raising of a belief in his own mind that the members of that House were heartily sick and tired of Medical Reform, as there had been already a number of bills before them relating thereto, and it had in consequence become very distasteful to them. Such being the case, he was induced to think, that if a bill, meeting the views of the general body of the profession, were submitted, the House would gladly pass it, in order to get rid of the subject and its (to them) attendant annoyance. (Applause.) Mr. Hastings, in proceeding to explain the bearings of the proposed measure, observed that they were already familiar to the members of the Association, a copy of the Bill having appeared in the *Journal*. After having given a short description of the principal provisions, he said, in drawing the draft of the Bill, it had been his earnest study to meet the views, and carry out the wishes of the great body of the medical profession throughout England; and it was his belief, that if the Association failed in the endeavour to carry out Medical Reform, no other single body would be able to take the matter up, and it must be allowed to drop; the consciousness of this ought, therefore, to incite them to a continued, vigorous, and united action. (Mr. Hastings sat down much applauded.)

Mr. WALLACE expressed his dislike of the manner in which the representative Council was to be constituted under the proposed Bill, and which, he believed, would not satisfy the profession, who required the representative principle to be fully carried out. He had stated this objection when the Draft of the Bill was under discussion by the Committee, and he hoped that the part relating to the constitution of the Council would be struck out.

A MEMBER said, that while two medical colleges had been spoken of as having been consulted, (the College of Surgeons and the College of Physicians,) no mention had been made of a third and no less important one—the Apothecaries' Company, to whom they were so much indebted. He thought that with respect to the Council, the selection ought to be made one-half from the general practitioners; and also that in the promotion of the Bill, the opinion of the Society of Apothecaries should be taken, and their support solicited.

Mr. STEDMAN, observing that the meeting was under obligations to the legal gentleman who had so ably addressed them, said the gentleman who had last spoken had expressed his regret that the Society of Apothecaries had not been consulted, he, however, had to mention that another equally important institution had been passed by—the Institute of Medicine and Surgery. As a member of the Council of that Institute, appointed by 4000 members, he could not allow the omission to pass without noticing it.

Mr. G. HASTINGS said it was but right he should

state, that when drawing up the draft of the first Medical Bill, he wrote, at the same time forwarding a copy, to the Society of Apothecaries as well as to the Colleges of Physicians and Surgeons, stating that he and the Committee were anxious to have their opinion in writing, or, if they would favour him with a personal interview, he would explain any portions they might wish. The Apothecaries' Company took no notice whatever of his letter; and when the second draft was drawn, he did not think it worth while to trouble them with it. As to the Institute of Medicine and Surgery, a similar course was taken in the first instance, which resulted in their giving notice of opposition to the Bill; and no application had been made in the second instance. (Loud cries of "Hear, hear.")

Mr. BOWLING (of Hammersmith) regretted that in the Bill there was no provision made for examinations in midwifery. He thought there were more lives unnecessarily lost in that branch of the profession than in any other. Some stringent statutory regulations were required to ensure to the public proper obstetric education.

The Rev. Mr. BELL said, that though the practice of medicine was no longer his occupation, and though he had assumed a still more sacred calling (applause), yet he was proud to continue to be a member of this Association, and had always much pleasure in participating with his medical brethren in the advantages of these annual meetings. (Applause.) Many years ago he had advocated changes not very different from those which were now so likely to be harmoniously carried out. He did not, however, like to trust all the details to any Committee; and he would wish to add to the motion a clause directing the proposed Committee to convene a special meeting of the Association to consider their amended edition of the Bill.

After some debate it was at last agreed (on the suggestion of Sir Charles Hastings) that the Committee should be instructed to communicate their amended Bill to the Central Council, by whom, if the alterations involved great changes, a special meeting of the Association was to be called. This arrangement gave general satisfaction, and terminated a discussion, which at first seemed likely to occupy a long time.

Mr. LORD (Hampstead) eloquently insisted upon the claims which general practitioners had upon society. Their position was not an inferior one; inferiority was the result only of misconduct and ignorance, and these might as easily degrade the pure physician and the pure surgeon as the general practitioner. He feared the representative system had been too much lost sight of in the Bill; but if a good Committee were appointed, he pledged himself to be contented with what they did, even though he felt that the Bill might not give all that was required by the profession. (Applause.)

Mr. HUNT wished to hear the names of the proposed Committee.

The PRESIDENT (after some discussion) thought that the best course would be to put the original motion; but if Mr. Hunt pressed an amendment, he would of course take the sense of the meeting upon it.

Mr. HUNT stated that he did not wish to put his suggestion as an amendment.

The motion of Dr. Robertson was then carried by an overwhelming majority.

Mr. PROPERT moved that the following gentlemen do constitute the Committee to take charge of the Bill:—Dr. Robertson, Mr. Cartwright, Mr. Walsh, Mr. Bree, Mr. Noble, Mr. Bottomley, Mr. Southan, Mr. Stedman, Sir Charles Hastings, Mr. Hastings, (Secretary,) and that five be a quorum.

Mr. NUNNELEY (Leeds) seconded this motion; which was unanimously carried.

It was then moved and seconded that Mr. Propert and Mr. Nunneley be added to the committee. Mr. Nunneley's name was added, with his consent; but Mr. Propert having excused himself from acting, in consequence of the great demands upon his time in connection with the Medical College, the name of Dr. Webster (Dulwich) was substituted for his.

Dr. EDWARDS moved that the thanks of the Association be given to the son of Sir Charles, Mr. Hastings, of London, for his talented and judicious exertions on behalf of the Association in the cause of Medical Reform. The bill was ably drawn up, and had, been most lucidly explained to them. This proposal was received with much enthusiasm, and was unanimously carried; whereupon the President thanked Mr. Hastings in the name of the Association.

AUDITORS' REPORT.

Mr. NUNNELEY, on behalf of the auditors, stated that they had gone through the accounts, and although they had no doubt of their being substantially correct, yet as the vouchers for some of them were wanting, they had not felt themselves justified in signing them. The auditors hoped that a better system of keeping the cash-account would be adopted in 1853; and that, in fact, a totally different system would be adopted, not only with the cash-account, but with all the other books, so as to render the business-transactions of the Society more clear than at present.

Mr. BARTRUM coincided with Mr. Nunneley's remarks, and described the mode of keeping the accounts as complex beyond measure. They were greatly obliged to the Secretary for the attention he had paid, and explanations given, and also for his promising to effect an alteration in this respect before the lapse of another year.

An Abstract Statement of the Income and Expenditure of the Provincial Medical and Surgical Association, from July 31st, 1851, to July 17th, 1852.

Audited and examined,
NASH AND WATKINS.

17th July, 1852.

BENEVOLENT FUND REPORT.

Mr. NEWNHAM then read the Report of the Benevolent Fund, which will be published in the next number.

Dr. FORBES, in moving “That the Report be received and adopted, and that the warm and grateful thanks of the Association are due, and are hereby tendered, to Mr. Newnham for his services to the Benevolent Fund, and that he be requested to continue his services as Treasurer and Honorary Secretary,” took occasion to allude to the benefits derivable from the establishment of a fund of this kind, and to urge the importance of the consideration upon all members of the profession.

Dr. JENKS, in seconding the motion, paid a deserved compliment to Mr. Newnham for his kind and charitable disposition, remarking that he possessed what was the most earnest aspiration of the devout Mahometan—“the prayers of the poor.” (Applause.)

The motion was unanimously carried.

Mr. NEWNHAM returned thanks in very appropriate and feeling terms.

THE ADDRESS IN MEDICINE.

Dr. EASON WILKINSON (Manchester) being called upon by the Chairman, read the Address in Medicine. In consequence of the shortness of the time remaining at the disposal of the meeting, he was compelled greatly to abridge his cleverly-written paper.

At the conclusion, Dr. WHITING, amidst much applause, proposed a vote of thanks to Dr. Wilkinson for his able and talented address, coupled with a request that he would allow the same to be printed. Dr. Whiting observed that he had the more pleasure in proposing the motion, because he thought the attention of the profession had not been enough directed to what was termed physical education, therefore it became them the more to take it up. This had been noticed

in the address which they had just heard. Great evils doubtless arose from a bad physical training of children; and he would suggest to the profession generally that there should be diffused among the public more information regarding this interesting subject. In his own neighbourhood he had adopted a plan which, as his time was not so much occupied in professional pursuits as formerly, he had been enabled to prosecute successfully, namely, the delivery of philosophical lectures in a popular form; the result of which effort had been his receiving the general thanks of the town wherein he lived. He thought if other professional gentlemen would take up the subject in a similar way in their respective localities great good would result. (Applause.)

Mr. WALLACE seconded the motion, which was carried *nem. con.*

THE ADDRESS IN SURGERY.

JAMES TORY HESTER, Esq. (Oxford) then delivered the Address in Surgery, which was extremely well received.

On the motion of Mr. HODGSON, seconded by Mr. CALEB WILLIAMS, a vote of thanks was passed to Mr. Hester for his talented Address, accompanied by a request that he would allow the same to be printed.

It was understood that the respective Addresses in Medicine and Surgery should appear in the "Transactions" or *Journal*, as decided by the Council.

ANNIVERSARY MEETING, 1853.

Sir C. HASTINGS called attention to the subject of selecting the town in which the Anniversary Meeting of the Association should be held next year. The Council had come to the understanding that it should be held at Cambridge; and that the Regius Professor of Medicine there should be proposed as President-elect. (Applause.) But they had also present among them a deputation from Swansea, the metropolis of South Wales, and equally connected with Bristol and Bath, who sought to obtain for that town the honour of their meeting. If the opinion of the Association should be favourable to this latter place, he should propose Dr. Gwynne Bird as President-Elect. They would recollect they would be opening up fresh ground in this quarter; and their friends had been pressing them repeatedly to go there. Then they had also present some friends from York, who wished to have the next Anniversary Meeting of the Association held in their city. They were, however, willing to waive their claims in favour of Swansea; and as regarded Cambridge, Dr. Bond had assured them that it would be for their interest to delay visiting that university for a twelve month. Their choice remained between the two, as to which was the most eligible.

Mr. HUNT moved that the choice of place for holding the annual meeting should be left to the Central Council.

Mr. HODGSON seconded the motion.

It was finally agreed that Swansea should be the place

of meeting, and that Dr. Gwynne Bird should be the President-Elect.

Dr. RADCLIFFE HALL, of Torquay, was formally requested to deliver the "Address in Medicine," and Mr. Prichard, of Bristol, the "Address in Surgery," at the next annual meeting.

Mr. MICHAEL (Swansea), expressed the gratification which the profession at Swansea and its neighbourhood would experience from the choice just made, and assured the members of the Association a hearty welcome. (Applause.)

COMMUNICATIONS.

The "Report of Cases in the Oxford Infirmary" was read by the House-Surgeon, Mr. HUSSEY, to whom a vote of thanks was duly passed.

JOSEPH TOYNBEE, Esq., F.R.S., F.R.C.S., Aural Surgeon to St. Mary's Hospital, &c., read an interesting paper "On the Use of Artificial Membrana Tympani, in cases of Perforation or Destruction of that Organ." After detailing the results of some researches into the functions of the membrana tympani recently laid before the Royal Society, in which it is shown that the guttural orifice of the Eustachian tube is closed except during the momentary act of swallowing, he pointed out the fact, that for the function of hearing to be perfect the sonorous vibrations communicated to the tympanum ought to be confined within the walls of this resonant cavity, that they may duly impress the membrane of the fenestra rotunda, and thereby be communicated to the internal ear. Inferring from these researches that the deafness attendant upon perforation or destruction of the membrana tympani is produced by a want of the due concentration of the vibrations, by their diffusion into the meatus, and their absorption by its walls, Mr. Toynbee suggested the use of some means whereby the orifice in the membrana tympani should be closed, and the tympanum again rendered a shut resonant cavity. After some experiments, he had an artificial membrana tympani constructed, by Mr. Weiss, composed of vulcanized Indian-rubber, in the centre of which is fixed a small plate of silver and a silver wire, whereby it can be introduced or withdrawn at pleasure. This artificial membrana tympani has already been applied with such complete success by several patients, that they are able by its aid to hear sufficiently well to carry on general conversation. One man, a patient of St. Mary's Hospital, who had been discharged from the army on account of his deafness, has entered upon his duties again. A young lady, who had not heard at church for many years, can now hear the sermon perfectly well. Patients can apply the artificial membrana tympani themselves, can remove it at pleasure, and its cost is not more than a shilling.

Dr. HITCHMAN (Derby) read a paper on "The Pathology of Insanity."

Dr. FORBES WINSLOW, referring in complimentary terms to the kind and hospitable reception which the members had experienced at Dr. Acland's *soirée* on the

previous evening, moved a vote of thanks to the Radcliffe Librarian, which being seconded by Mr. NEWNHAM, was carried unanimously.

Dr. CONOLLY proposed a cordial vote of thanks to the Vice-Chancellor, Heads of Colleges, and the Local Authorities, for the extremely kind reception which had been afforded the Association.

Dr. RADCLYFFE HALL seconded the motion, which was carried by acclamation.

The PRESIDENT having vacated his seat, the same was thereupon taken by Sir CHARLES HASTINGS, who, in suitable terms, proposed a vote of thanks to the President, upon whose conduct in presiding over the proceedings of the anniversary he passed a just and well merited eulogium.

Mr. TOYNBEE seconded the motion, which was instantly agreed to.

The PRESIDENT was happy to find his conduct had given them satisfaction, and he sincerely thanked them for their kind expressions of esteem.

The business proceedings of the anniversary then terminated.

Professor QUEKETT gave a microscopic demonstration in the Anatomical Museum of Christ Church College, at three o'clock, P.M.

REPORT OF THE MEETING OF PROVINCIAL PHYSICIANS AT OXFORD ON THE PROPOSED NEW CHARTER OF THE ROYAL COLLEGE OF PHYSICIANS.

Agreeably to previous arrangements a number of British Graduates, members of the Provincial Medical and Surgical Association, assembled in the Divinity School of the University of Oxford, on Thursday, July 22nd, (permission having been previously obtained). Among the gentlemen present we observed Sir C. Hastings, M.D., D.C.L., Worcester; A. Robertson, M.D., F.R.S., Northampton; J. McCoragher, M.D., Edin., Chichester; W. P. Brookes, M.D., St. A., Cheltenham; E. Mainwaring, M.D., Glasg., Bournemouth; H. Cooper, M.D., Lond., Hull; T. G. Hake, M.D., Glasg., Bury St. Edmunds; Forbes Winslow, M.D., Aberd., F.R.C.P., Edin., London; J. C. Cookworthy, M.D., Edin., Plymouth; James Tunstall, M.D., Edin., Bath; E. Howell, M.D., Edin., Swansea; C. R. Hall, M.D., Torquay; A. Eves, M.D., Cheltenham. Dr. Roberston was unanimously voted to the chair.

After a preliminary conversation, in which the bearings of the proposed Charter, in relation to its effects on the provincial physician, was fully gone into, the following resolution, proposed by Dr. Forbes Winslow, and seconded by Sir Charles Hastings, was unanimously carried,—

“That the cordial thanks of this meeting be tendered to the President and Fellows of the Royal College of Physicians of London for the extreme liberality displayed in the provisions of the proposed Charter of incorporation; at the same time the meeting beg to suggest to the President and Fellows, whether the clause relating to the fees payable upon the admission to the membership by those who, at the date of the Charter,

are graduates in medicine of British Universities, be not open for reconsideration, with the view of reducing the amount to be paid for the diploma itself, especially by those who have long practised beyond the jurisdiction of the College, and of endeavouring to exempt all candidates, being graduates of British Universities, from payment of £15 stamp duty, they having already paid a stamp duty on taking their degree.”

Proposed by Dr. Brookes, and seconded by Dr. Cookworthy, and unanimously resolved,—

“That a Committee be formed, to communicate with the Royal College in relation to the proposed Charter, and that it consist of Sir C. Hastings, Dr. Winslow, Dr. Eves, Dr. Hake, Dr. Tunstall, Dr. Brookes, and Dr. Cookworthy; that Dr. Tunstall be requested to act as Honorary Secretary, and that he do communicate the above resolution to the Registrar of the Royal College of Physicians.”

Thanks being voted to the Chairman, the meeting adjourned.

JAMES TUNSTALL, Hon. Sec.

THE DINNER

Took place at the Town Hall, at seven o'clock, there were about 180 gentlemen present. The President of the Association, Dr. Ogle, took the chair, and among those near him were the Vice-Chancellor of the University, (Dr. Plumtre,) Sir Charles Hastings, M.D., Dr. John Conolly, Dr. Jenks, (late President,) Sir C. Clark, Dr. Acland, Dr. Forbes, (President of the Royal College of Surgeons,) Dr. South, (ex-President of the Royal College of Surgeons,) the Bishop's Chaplain, Wm. Ward, Esq., (Mayor of Oxford,) Mr. Alderman Spiers, (Sheriff of Oxford,) the Senior Proctor, the Junior Proctor, Dr. Shepherd, Dr. Jackson, Dr. K. Shepherd, Dr. James, (Vice-President,) W. Cleobury, Esq., James Torry Hester, Esq., G. P. Hester, Esq., (Town Clerk,) F. Symonds, Esq., J. L. Hansard, Esq., (Local Secretary,) Dr. Giles, J. Godfrey, Esq., T. Allen, Esq., J. Freeborn, Esq., (J. Martin, Esq., W. Rusher, Esq., J. P. Sheppard, Esq., (General Secretary,) — Briscoe, Esq., A. Paul, Esq., Mons. Battel, and many other distinguished names in the profession. The repast, which was of first-rate character in all its appointments, was furnished by Mr. Holland, of the Cross Inn. Grace was said by the Vice-Chancellor.

The tables having been cleared, the PRESIDENT rose, and gave the health of “Her Majesty the Queen,” (three times three,) Grimmer's Quadrille Band, stationed at the upper end of the room, playing the National Anthem, the company joining in chorus.

The PRESIDENT next proposed the health of “Prince Albert,” (cheers); might he long live to foster by his example the social and domestic virtues, and the arts by his patronage. With the toast he would couple the healths of the rest of the Royal Family.” (Drunk with applause, the band, at the request of the President, playing the air,—“Dulce domum.”)

In proposing the toast of “the Bishop of Oxford and the Clergy,” the PRESIDENT said that on the like festive occasion last year, at Brighton, they were favoured with the attendance of the Bishop of Chichester; and he was authorised to state, that the Bishop of Oxford would have been present with them that day, had it not been for an unexpected engagement. He regretted they were deprived of an opportunity of listening to the

fervid eloquence of the respected prelate, (hear, hear;) but, however estimable the prelates of the Church might be, they must entertain as great respect for the parochial clergy, for few had more opportunities of noticing the Godly spirit and self-denying zeal with which these men discharged their duties than had the practising members of the medical profession. (Cheers.) The toast was drunk with three times three.

The BISHOP'S CHAPLAIN acknowledged the toast, expressing regret for the absence of the Lord Bishop, and commenting on the connection existing between the studies of theology and medicine. He showed how religion had taught the way to render patient and submissive the mind, under circumstances which to the heathen alike of ancient and modern times would have rendered life itself unendurable; and how the researches of medical science had given such a knowledge of the subtle diseases to which the human frame was liable, as to be enabled successfully to treat and overcome those hitherto deemed incurable. On the part of the Bishop and Clergy he returned them his most sincere thanks for the compliment they had paid them, and he hoped that both the members of the medical profession and the clergy would, in their several vocations, labour for the good of all. (Cheers.)

The PRESIDENT proposed the "Army and Navy, and especially the medical branches connected with both Services." (Much cheering.)

Air—Band—"British Grenadiers."

The PRESIDENT next gave "The Vice-Chancellor and the University Authorities." (Cheers.) He noticed the presence of the Vice-Chancellor and Proctors as a graceful compliment to the Association; and concluded a short but fervent address, by expressing an earnest hope that the University of Oxford—that venerable and venerated institution—might long prosper and continue to diffuse sound learning, and that sound religion, good morals, and just and liberal principles might ever flourish and abound within its walls. (Drunk with three times three, and one cheer more.)

The VICE CHANCELLOR and Proctors rose, and were received with renewed applause. On its subsidence the former said it had been a matter of great gratification to every member of the University in having an opportunity of showing every attention to such an honourable body as were the members of this Association, who had reflected honour upon it by holding their anniversary meeting this year at Oxford. It would have been hard indeed if this University, which was always anxious to pay a compliment to those distinguished in literature and science—(cheers)—and especially to those whose lives were devoted to the physical amelioration and improvement of mankind—it would, he repeated, have been hard indeed if the University had not felt and testified gratification at receiving so many members of the medical profession as he had now the honour of seeing around him. (Cheers.) Not only were the University glad to pay a compliment to men so eminent in scientific research, and in the distinguished services which they had rendered in their several paths of life—but he (the Vice Chancellor) might truly say that the names of many present would go down to posterity in connection with institutions which have for their object the amelioration of the ills to which

humanity is subject. (Applause.) He trusted this University would always give such an education to her sons as would combine religion with science—(hear, hear)—and that such had been the case might, he thought, be seen in the establishment of hospitals and similar institutions to administer to every affliction which it had pleased God to put upon them. (Cheers.) He wished to propose a toast. The University had yesterday the honour of enrolling among its members three distinguished men, belonging to the Provincial Medical and Surgical Association, upon whom the Honorary Degree of D.C.L. was conferred in the Theatre. He wished to be allowed to say that he trusted the compliment which was paid to those three gentlemen would be considered in some measure as a compliment also to the whole body of the profession. (Cheers.) It would be obvious that but a limited number must be selected on whom to confer degrees, and therefore he repeated that the selection made was intended as a compliment to the profession at large. (Renewed applause.) He had now very great pleasure in proposing that they should drink the health of the three distinguished individuals whom the University had yesterday the honour of enrolling among her members in the Theatre—namely, Sir Charles Hastings, M.D., Dr. Forbes, and Dr. John Conolly. (The toast was drunk with great applause.)

SIR CHARLES HASTINGS said, Mr. President, Vice-Chancellor, Proctors, members, and friends,—I had yesterday the pleasure, in a comparatively private party, of returning my grateful thanks to the Vice-Chancellor and Proctors of this University, for the very distinguished honour that was conferred upon me and my two friends, Dr. Forbes and Dr. Conolly, (whom I see around me on this occasion, (cheers,)) on the assembling of the Provincial Medical and Surgical Association in this ancient and venerated University of Oxford. I need not say that the compliment to which I have referred is one of the most distinguished compliments that can be paid to any person, belonging to any profession. (Cheers.) I need not say that to be thus complimented is indeed an honour in such a place—where some of the most eminent of statesmen, philosophers, and poets, born in this and every age since the University existed have received the like distinction; and, gentlemen, I need not say that this honour, received through three individuals, is a most distinguished and positive compliment to the whole profession, and such an one as was not contemplated as likely to be received by this Association from so distinguished an University as that of Oxford. (Applause.) It is impossible for me to find language adequately to express my feelings for having been placed in so distinguished a position; and if it was possible to enhance that distinction it arises from the fact that I was accompanied by two friends to whom I have been for years most affectionately and tenderly attached. Gentlemen, I say, if it were possible to have added to the distinction, it was in being selected in conjunction with two gentlemen who occupied a position compared to which I feel my own unworthiness. And I cannot but think that the fact of being selected with those honoured gentlemen was in consequence of my having taken an active part in the concerns of this Association; for I consider myself otherwise unworthy of

the high distinction that has been conferred on me. (No, no.) I can say that the University of Oxford will ever receive from our profession every possible endeavour to do her no discredit, and that by continuing to ameliorate human nature, we hope to fulfil the destiny to which providence has called us. (Sir Charles resumed his seat very warmly applauded.)

The PRESIDENT then gave—"The President of the Royal College of Physicians, and the President of the Royal College of Surgeons," which was duly honoured.

The PRESIDENT of the Royal College of Surgeons returned thanks, and expressed a fervent wish that the present anniversary might prove an earnest that in future the profession would be closely combined, and that by-gones would be no more remembered. In the course of his remarks he enlarged upon the Charter of the College, and on the importance of a sound education to their profession as the basis of future eminence and success, and alluded in grateful terms to the feelings which must have imbued their minds while wandering along the banks of the far-famed Isis, and breathing the atmosphere of learning in this ancient University.

The PRESIDENT, in proposing "The Mayor and Corporation," remarked that there was not a more loyal, hospitable, or courteous body than the Corporation of the city of Oxford. (Great applause.)

The MAYOR returned thanks, and after expressing the gratification it had afforded him in offering the city buildings to the Association, remarked upon the importance of the medical profession, and paid a compliment to the President and other resident members of the profession, remarking that they were second to none in the talent and humanity displayed in administering to the "ills that flesh is heir to." (Cheers.)

The PRESIDENT next proposed the health of "The Founder of the Association, Sir Charles Hastings," whom he warmly eulogised for the zeal and energy with which he had always attended to the interests of the Association. Might he long live to enjoy the respect which was so deservedly his due, and to witness its continued prosperity and increasing success. (Cheers.)

Sir C. HASTINGS said, I rise on this occasion, for the twentieth time, to thank you for the honour you have done me in drinking my health on a similar occasion to the present. It is, gentlemen, now twenty years ago that this Association was established at Worcester, when some members of the medical profession—some of whom (alas! how few) were present with them that day—met for the purpose of forming themselves into an association, whose object should be the protection of the interests of medical science, and the promotion of peace, good-will, and harmony among the members of the medical profession. Gentlemen, this was the origin and design of our Association,—these the mottoes on our banner; under it we have prospered hitherto, and I hope we shall continue to prosper. As regards the present condition of the Association, I may say,—

"Si monumentum queris, circumspice."

(Cheers.) Many and great objects have engaged our attention; we have buckled on our armour, and fought the battle manfully; we have hitherto succeeded, and now stand in a position at the present time, notwithstanding all that might have been said to the contrary, more proud than at any preceding anniversary. (Hear,

hear.) We have received from the University strong and convincing proof that our exertions have been appreciated by the great, the noble, and the good. (Cheers.) What greater reward can the exertions of good men receive than the meed of praise of those who are capable of estimating those exertions. (Hear, hear.) That we have this reward is patent to us all. Has not the Vice-Chancellor told us that he regards our Association as a most important one? and are we not placed in this high and honourable position, not only because the Association is esteemed for what it has already done, but also for what it proposed to do? Let our watchword then be—"Onward." (Cheers.) Let us look at the difficulties which beset medical legislation, and then consider what has been accomplished with respect to it. When we first met at Worcester, the medical corporations of the metropolis were hostile to their brethren in the provinces; but now the President of the Royal College of Physicians, the President of the Royal College of Surgeons, and the Head of the Apothecaries' Company, have all come to wish us "God speed," and to say they will help us. (Great applause.) This then, gentlemen, is our triumph,—may we go on prospering and to prosper. I care not what is said, here are 1632 members united together in one bond, desirous of advancing the profession, and showing that they love one another. (Cheers.) This is true philosophy,—this is Christian philanthropy. (Hear, hear.) I care not what some parties may say about our not advancing; I affirm we are advancing in our onward course,—that we do improve the profession by administering to the ills of humanity. (Cheers.) We will continue in this good course; the medical corporations and ourselves will pull together in this great and grand work, until we have placed our profession on the highest pinnacle of fame it is destined to occupy, and which it must occupy in future and better times. (Much cheering.) Gentlemen, I thank you most sincerely for your kindness; and with regard to our great, noble, and flourishing Association, all I can say is—*esto perpetua*. (Renewed applause.)

The PRESIDENT of the COLLEGE of SURGEONS then proposed, in suitable terms, the health of Dr. Ogle. (Much cheering.)

The PRESIDENT, in returning thanks, said he ascribed his appointment to his high position as President of that Association, more to their kindness than to any merits of his own. (No, no.)

Dr. JOHN CONOLLY, being called on by the President, rose and said: Mr. President and gentlemen, I have the honour to remind you of one of the most brilliant, scientific, and hospitable entertainments ever offered to the members of this Association in any of their meetings in past years. I am quite sure that every gentleman who had an opportunity of being present last night at the *conversazione* at the Radcliffe Library—(prolonged applause)—that every one on leaving that institution must have said to himself, "Here, at least, have I passed one or two of the most intellectual hours of my existence." (Cheers.) He must have felt all the better qualities of his intellect, and all the better feelings of his heart, called forth by witnessing all that the human intellect has brought into play up to the present time, by the kindness of one of

the most intellectual, accomplished, and amiable men that any of us have the privilege to call our friend. (Cheers.) I see that you receive these simple words of mine with the utmost enthusiasm—"We do,";—not from the value of the words themselves, except that they faintly express the feelings of every man's heart in this room. I think there are none of us provincial people who have come here to Oxford but must feel perfectly overpowered by the grand spectacle afforded by this great University; as we walk among the monuments of learning, and the great schools, which must exercise such an influence on mankind, and reflect that they are presided over by men who have received us with such kindness, and who are distinguished for their kindness and warm cordiality—I say we must feel gratified, after all the great and the learned are ready to do their utmost to evince their respect and honour towards us, and this, too, in such sincerity and kindness. (Much applause.) I think all must be impressed with that feeling, and that we shall go away from this city impressed with that feeling—(hear, hear)—impressed with feelings of affection and regard towards this University, and inclined to exclaim—"Never mind, there may be faults and defects in these ancient institutions, but there is also something great and grand in them"—(cheers)—and sufficient to excite regret that many like himself should not have had the opportunity of being educated therein. We all can see that we might have been more useful in our profession and better citizens; and notwithstanding this, we have been received here with kindness as belonging to the great family of mankind. (Cheers.) Last night we were entertained under the magnificent roof of the Radcliffe Library by one of our own profession, where we saw all that could charm the intellect, engage the affections, and enlighten the understanding; and we felt, above all, that we were there under the auspices of a gentleman, of whom it is no empty praise to say, that he is one of the lights, and also one of the great charms of the profession at the present day. Gentlemen, I thank you for your patient attention—you are always but too indulgent to me. ("No, no.") I beg to propose that we drink "The health of Dr. Acland." (Prolonged applause.)

Dr. ACLAND (Radcliffe Librarian) returned thanks, and in so doing said:—If in attempting to receive you last night I had been actuated by any personal motives, I could not have now addressed you. Dr. Conolly has been pleased, in most eloquent language, to paint the feelings of his heart rather than the circumstances I had myself been engaged in on the preceding day. A good painter, if he paints at all, paints not what he sees but what he feels. (Cheers.) I will at once dismiss any personal consideration, but I think you will believe me when I say that in inviting you last night I asked you not to meet me, but to meet together at the Radcliffe Library. (Hear, hear.) That Library was founded by a physician, and its trustees have devoted it to medical and natural science. When the office of keeper was vacant, several candidates appeared. I was induced to offer myself as a candidate in the hope that the office might not pass out of the hands of the profession. Your President (Dr. Ogle) will remember

that I said to him in a narrow lane in Oxford, soon after the lamented death of Dr. Kidd, that the Regius Professor of Medicine, whoever he might be, certainly should have the dome of the Radcliffe Library as his official residence. (Cheers.) At that time I had not the slightest reason to believe that the office of Librarian would be conferred upon me; but I wished that he who was at the head of medicine in Oxford, should be at the head of the Library also. (Hear, hear.) The Radcliffe Library is placed within the walls of Oxford, one of the most ancient Universities in the world. Now, but few medical men issue forth from this University; and this, I contend, is wrong. The work of education in Oxford, in respect of medicine, is defective. (Hear, hear.) Although I appear here as one of her youngest officers, I am anxious that this opportunity shall not be lost of making known that Oxford has a great work to do for itself and for the country in this respect; and that she can and will do it. (Hear, hear.) Gentlemen, I know how you felt last night at the Library; by what you there saw I know you were satisfied. (Cheers.) And why satisfied? Because you met in a great artistic edifice, second to none in Europe;—you met your President;—you saw represented there *art*;—and you also recognised in the persons of the Vice-Chancellor and the Proctors the representatives of *learning*. (Applause.) Because, in addition to the improvements of Weiss, of Smith, and others, you saw there representations of *science* in the deeper and hidden paths, made known in the works of Cuvier, Owen, and other great men. Trained in such ways the medical student, when looking upon any organic structure (the *dry bones*, as formerly called), whether healthy or morbid, will see in it some sort of an expression of the laws of nature which God has implanted therein. (Hear, hear.) Dr. Acland, after some other observations, concluded by stating that he attempted thus humbly to represent in this University those feelings of learning and truth which were shared by all, in a greater or less degree, and which made them all so happy last night. (Dr. Acland then resumed his seat, whereon the whole company rose and gave him three hearty cheers.)

The PRESIDENT proposed "The health of Mr. South, ex-President of the College of Surgeons." (Cheers.)

Mr. SOUTH returned thanks, and gave "The Medical Profession in Oxford."

Mr. CLEOBURY returned thanks as senior surgeon; but unfortunately spoke in so low a tone of voice as to be inaudible except in his immediate vicinity.

The next toast from the chair was, "The health of Dr. Jackson (Physician to the Infirmary), and the Staff."

Dr. JACKSON expressed his sense of the honour conferred, which he said was as unexpected as undeserved.

The PRESIDENT then proposed "The health of the ex-President, Dr. Jenks." (Great applause.)

Dr. JENKS, in returning thanks, said it was now thirty years since he had paid a visit to Oxford. He felt sure that no place could vie with it either in the number and extent of its public buildings, nor yet in the magnificence of their endowments; and equally certain was he that no place could have been found where so

scientific, delightful, and successful a meeting could have been held as the present had been. (Cheers.)

Dr. ACLAND proposed, "The health of Professor Quekett, and all the various 'artizans and labourers' who had assisted the Association on the preceding night;" and signified his regret for the Professor's absence from the festive board. He alluded to the great advantages derived by the surgical profession from the inventions of scientific artists.

The PRESIDENT next gave "The health of Mr. Hansard, the Local Secretary, and the Dinner Committee." (Cheers.)

Mr. ALLEN (Oxford) acknowledged the compliment.

Dr. FORBES gave "The health of the Vice-Presidents," coupling with it the name of Mr. James, of Exeter, at which place it would be remembered the Association met with a very hearty reception. (Cheers.)

Mr. JAMES, in acknowledging the toast, testified to the pleasure it had always afforded him to aid Sir Charles Hastings in promoting the interests of the Association, and expressed himself much gratified that harmony had been brought about between the members of the profession in the metropolis, and those in the provinces, a state of things which he hoped would long continue to exist. (Loud cheers.)

The PRESIDENT then left the chair, it being eleven o'clock, and the proceedings of the Twentieth Anniversary terminated.

Provincial Medical & Surgical Journal.

WEDNESDAY, AUGUST 4, 1852.

WE insert the report of the proceedings at Oxford exactly as furnished us by the reporter appointed by the Central Council, and we do not, therefore, hold ourselves responsible for its accuracy, though, in the main, we believe it to be a faithful record of this remarkable meeting.

We have styled it remarkable, inasmuch as it has been distinguished by careless misstatements of facts which have been brought forward by gentlemen in the heat of debate, for whose veracity we have the greatest respect, and who, we verily believe, were actuated by a sincere desire to advance the cause of the Association, and of the profession at large. But it has also been remarkable for the most curious termination of a debate, founded upon these false data, which ever occurred in any society of educated men. For it is the fact, as recorded by our reporter, that after the amendment of Mr. NUNNELEY had been negatived by a majority of two, and after the triumphant party had insisted upon the right which their slender majority gave them, of carrying out their intention, (appealing to the

custom of the House of Commons,) they yet, apparently overwhelmed by success, neglected to follow up their victory by having the original motion carried. We can only account for this by supposing that they were not prepared for their success; but whatever the cause, certain it is that if tried by the customs of the tribunal to which they themselves appealed, (the House of Commons,) it will be found that we are just as if nothing had been done at Oxford *quoad* the change of place for publication. We do not know, nor do we individually care, what may be the result, but we are quite clear that such is the state of affairs; and it is still more unfortunate that no special meeting can rectify the error, for every change of law must be made at an *anniversary* meeting.

We have taken no part whatever in the late debate in defence of the *Journal*, because we could not conscientiously say that we thought it as good as it might be made; but we did expect, that when a fair and impartial Committee was offered, and of which the members were approved of by Dr. COWAN, to investigate the reasons of our want of success, with full power to do all which was contemplated by Dr. COWAN, if so decided by them;—we repeat it, that we did expect that a society of gentlemen, and men of education, would not have refused that trial and investigation which every one has a right to ask, and in this country has usually only to ask in order to receive. We therefore cannot do otherwise than feel some slight exultation, when we find a party, who were so ready to blame others for neglect of duty, themselves neglecting so obvious a termination to their labours. And we rejoice, for the sake of the Association and for the sake of the profession to which we belong, that there will be an opportunity offered next year of cancelling the act of injustice which has been so nearly committed, by going into the investigation in a full and satisfactory manner.

That an act of injustice was attempted, is quite clear, since it is impossible to go into such a complicated business in a general meeting, *unless that meeting resolves itself into "a Committee of the whole house;"* for after the party attacked has once spoken, he must keep silence, let what may be said, as was the case on the recent occasion.

We are not now going to attempt a refutation of Dr. Cowan's positions, which, when stripped of the eloquent language in which they were

wrapped, amounted simply to these three propositions:—1st, that the Association was going down in its number of “subscribing members;” 2nd, that the cause of this defalcation is, that the *Journal* is not what it ought to be; and, 3rd, that the only way to make it so, is to remove it to London. But, as we have publicly made a statement to the effect, that the number

of “subscribing members” was never so large as at present, which statement was as publicly disputed—for it cut Dr. COWAN’S ground from under his feet—we publish the following table, which shows the *apparent* number of members in each of the last twelve years, together with the *real* money-receipts in each year, which last is the only test of the advance of the Association.

YEAR.	Members.	Gross receipts, including Balance in Hand.		Balance in hand.		Nett Receipts, Deducting Balance.		Average of three years.	
		£	s. d.	£	s. d.	£	s. d.	£	s. d.

1851	1506	1726	18 1	109	18 1	1610	19 7		
1852	1632	1638	18 8½	94	3 1½	§1544	15 7		

* Year in which defaulters were first struck off.

† Great exertions were made this year to get in the arrears in consequence of the payment to Dr. Hennis Green.

‡ First year of office held by Mr. Sheppard, when the arrears were worked up very closely.

§ This year only consisted of eleven months, in consequence of the anniversary meeting occurring one month earlier than usual, otherwise the receipts of the year would have exceeded £1600, and consequently, the average of the three years would have been about £1620.

From this table it will be seen that, making allowance for the last short year, our receipts in the last three years have averaged about £100 per annum more than the average of the previous three years, or of the average receipts of 1845, 1846, and 1847, the years selected by Dr. COWAN, which were £1516. 3s. 2d. This carelessness in making his calculations of the past on the part of Dr. COWAN, who had every opportunity of referring to the reports published year by year in the *Journal*, is sufficient to lead us to suppose that he is equally incorrect in his budget for 1853. But here we cannot possibly disprove his assertions, since we have failed, both publicly and in private, to obtain a sight of those calculations upon which he based his proposition. We can only say, *ex uno disce omnes*.

As we premised in the early part of this article we do not charge Dr. COWAN and his party with more than carelessness, but of this they must stand convicted by the evidence of figures which cannot be controverted. We know that these mistakes might easily be made, but

we think that due care was not taken in so grave a matter; and we contend, that when the whole basis of calculation adduced by one gentleman, is disputed by another, the least that the former can do is, to go into the matter and settle its truth before proceeding to an irrevocable decision upon it. Such was the course we should have expected from Dr. COWAN, and such, we think, on cool reflection, he will himself consider ought to have been taken.

We have, in justice to ourselves, thought it right to publish the above remarks on the past, and for the future we have only to remind the members of the Association, that as the sole responsibility of the conduct of the *Journal* devolves upon us, by the resignation of Dr. RANKING, we trust that we shall have their support so long as we hold the office of Editor. We have been asked to do so until a successor is appointed, and though burning with a sense of the injustice committed, we have complied with the request, and whether we hold that office for six months or longer, we will leave no stone unturned

to improve its management. From some experience in this arduous duty, we believe we have arrived at a knowledge of the causes which have impeded that full success which all have equally at heart, and whether as Editor, or as a member of the Central Council, we shall at all times be ready to give the results of our experience to any Committee, either large or small, which may be empowered to investigate this important element in the success of the Association. But it neither comports with our ideas of professional decorum nor of the character of a gentleman to bandy words in an assemblage of excited partizans.

It is a common proverb that "lookers on see the most of the game," and we therefore are induced to insert the following extract from the leading article of the *Medical Times and Gazette*, which puts the matter in so clear a light, that it is unnecessary for us to do more than thank our *confrère* for his kind and complimentary defence of our position:—

"Admitting the expediency of the Association having its own organ, of which we have some doubts, the question of removal turns entirely on two points—Can the *Journal* be got out cheaper in London, and can its matter be better done? With regard to the first point, no very satisfactory evidence was laid before the meeting. Dr. COWAN stated that the *Journal* could be published in London for £1200 a-year, and Mr. WALSH disputed the fact. With respect to the second point, we take leave to say, that the scientific value of the *Journal* must depend entirely on the members of the Association themselves. The original communications are the mainstay of a scientific journal; and, unless there are good contributors the best Editors in the world would make a mess of it. No one can deny, indeed, the ability of Dr. RANKING and Mr. WALSH; and we doubt whether the Association can procure any Editors in London who are better qualified than these two eminent practitioners. Would, then, the mere publication in London improve and widen the class of original contributors? We doubt it very much. It is the circulation of a journal that draws contribution. Men make known their labours through the medium that gives them the greatest publicity. One speaker said, at the meeting, that good writers, when asked to contribute to the *Journal*, replied, that they "would not bury their articles in that catacomb." But there are journals in London, as well as in Worcester, which are merely decent burying-places for non-viable essays. The experiment has already been tried by the Provincial Association, and proved

to be a failure; the next time it is tried, the result will be the same.

"If the members of the Association do not like their *Journal* to be a "catacomb," let them put into it something that has vigour, and will live. They are the real culprits in this matter, and not those scape-goats—their Editors. We believe that Dr. RANKING and Mr. WALSH have been most unhandsomely treated. We have not hesitated to differ occasionally from the *Provincial Journal*; but we have always had a sincere respect for its Editors. They have, we believe, done all that men could do; but they have been lukewarmly supported by the great body of their members, and have been cramped by want of funds. If the members of the Association want a good journal, they must work for it, and they must pay for it, and then they may publish it, if they like, at the Land's End."

Correspondence.

ON THE CASE OF DOUBLE AMPUTATION REPORTED BY "NIL DESPERANDUM."

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In a case of double amputation related by "Nil Desperandum," the patient does not appear to have had chloroform administered. Would you ascertain the reason, as I am very much interested, having lately had occasion to perform the operation twice, in neither of which was it deemed advisable to use the remedy. If this should involve much trouble, pray think no more about it.

Yours very truly,

JOHN LAWRENCE, JUN.

[As we have not the address of "Nil Desperandum," we shall be obliged by his answering the above question.—
ED. J.]

Medical Intelligence.

DEATH OF MR. VINCENT.

The medical profession and the public generally will regret to hear that this estimable gentleman expired suddenly on the evening of the 17th instant, at his country house, Woodlands Manor, near Wrotham, Kent. Mr. Vincent commenced the study of the profession under the late Mr. Long, of Lincoln's Inn Fields, and was the last and favourite apprentice of that gentleman; and, at his master's death, succeeded to his practice, which he carried on until a few years since, in the same house, exactly opposite the College of Surgeons. Of this institution he became a member on the 20th of March, 1800; and on the 12th of July, 1822, he was elected a member of the Council, in the vacancy occasioned by the decease of Mr. George Chandler. Previously to this, however, he had been appointed an Assistant-Surgeon to St. Bartholomew's Hospital, from

which establishment he lately retired as Senior-Surgeon, with the respect and admiration of his colleagues, pupils, and numerous friends, who immediately opened a subscription to present a testimonial of their esteem to a man who had conciliated all parties by the extreme kindness of his disposition, and strict attention in the performance of his duties. On the 5th of January, 1828, Mr. Vincent was elected a member of the Court of Examiners, in the vacancy occasioned by the resignation of Mr. Thompson Forster; and on the 13th of July, 1832, he was unanimously elected President of the Royal College of Surgeons; in 1840, this honour was again conferred on him; and no doubt many who read this short biographical sketch of the deceased will remember the eloquent tribute paid to him by Mr. Luke, in the last Hunterian Oration. The deceased has left a widow and three sons; the eldest, John Vincent, is a barrister-at-law; the second is the Rev. Osman Vincent; and the youngest, the Rev. Richard Painter Vincent, is the perpetual curate of Woodlands, near Wrotham, Kent; a Church built, and to a great extent endowed, through the instrumentality of the family.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted on the 16th instant:—William Edward Ayerst, London; George William Callender, Clifton, Gloucestershire; Alexander Mackenzie Edwards, London; Henry James Ellery, Truro, Cornwall; James Hartley, Settle, Yorkshire; John Whitaker Hulke, Deal; George Allan Hutton, Newcastle-upon-Tyne; Charles Row, Shaldon, Devon; David Augustus Martin Talbott, Wrexall, Somersetshire; George Terry, Northampton.

The following gentlemen were admitted on the 19th instant:—William Bruce Armstrong, Dublin; John Milford Barnett, Belfast; Arthur Cuthbertson Edwards, Vanburgh Fields, Blackheath; Frederick Hall, Lincoln; Robert Knaggs, London; William Jackson Marshall, Ilkington, Derbyshire; Frederick Moon, London; James William Moorhouse, Australia; William Overend Priestley, Leeds; Otway Buxton Thibou, St. John's, Antigua, West Indies; Thomas Webb, Stratford-on-Avon, Warwickshire.

The following gentlemen were admitted members on the 23rd instant:—George Allcard, London; David Arthur, Neath, Glamorganshire; Richard B. Benson, Bayswater; Ebenezer Davies, Swansea, Glamorganshire; James Doubleday, Blackfriars Road; Wm. Edmunds, Canterbury; William Greenfield, Belfast; Joseph Kaye, Bombay; Henry John Davis Matthews, Camberwell; Henry Gaitskell Nurse, Montague Place, Islington; Edward Cooper Willis, Leamington, Warwickshire.

The following gentlemen were admitted on the 26th instant:—Thomas Brookes, Whitechurch, Salop; Henry Wm. Prattenton Brydges, New York; Thomas Quiller Couch, Polperro, Cornwall; James William Duffy, Chili, South America; Alfred Edmund Gabriel, Col-lumpton, Devon; Alfred Hedger, South Street, West Square, Southwark; Richard Hosking, Marazion, Cornwall; Henry Osborne, Northampton; Henry Sacheverel Edward Schroeder, Australia; Reginald Bayley Walters, Winchester.

The following gentlemen were admitted on the 28th instant:—Alexander Mundell Champneys, Mile End New Town; Clark Armstone Duckett, Spalding, Lincolnshire; Leopold Beharrell Fox, Shoreditch; Wm. Price Jones, Bala, North Wales; Marten Perry, Aylton Court, Ledbury; John Denning Tucker, Sheepwash, Devon.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 15th July:—Capel Bringloe, Beccles; John Cautley, Hedon, York-

shire; John Henry Gould, India; Harry May, Staffordshire; Peter Wood Spark; Algeron Sudlow, Weybridge; Charles Whitefield, Barnstaple, Devon.

Gentlemen admitted members on the 22nd July:—Henry Ayliffe, Adelaide, South Australia; Augustus Edward Davies, Rutlin, North Wales; Eugene Burke Durkan, Liverpool; Hanson Evison, Hull; John Wm. Howard, jun.; William Aston Lewis, Alderley; Edmund Shaw, Thatcham, Berks.

APPOINTMENTS.

Mr. Wildbore, of Charlotte Street, Fitzroy Square, and Mr. Adams, of Gloucester Crescent, Regent's Park, have lately been appointed medical officers for the western and north-western districts of St. Pancras.

KENT OPHTHALMIC HOSPITAL.

Major Wayth has bequeathed £100 to this charity; Miss Waller, of Sandwich, has also presented £20 towards the building fund.

OBITUARY.

July 10th, at Midhurst, Sussex, aged 30, Dr. Gosden, Assistant Staff Surgeon, and late of H.M. 84th Regiment.

July 13th, at Oldham, Thomas Fawsitt, Esq., a very active member of the Association.

LECTURES

ON THE

DISEASES OF CHILDREN,

DELIVERED IN THE

Chatham Street School of Medicine, Manchester.

BY DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Vienna, etc.

LECTURE XI.

Fevers in their objective appearance in infants and children under three years; their more alarming aspect; relation of different ages, to different kinds of fevers. The principal symptoms and their comparative analysis. The whole objective description of a primary paroxysm. Comparative and synthetic procedure in forming our opinion on a recently-developed fever; prudent reserve of the practitioner; changes to be expected within the first thirty-six hours.

GENTLEMEN,—Having in the former series of lectures exposed what I would call preliminary notions, I come now to speak on special diseases. I intend, before all, to devote a few lectures to *fevers in infants and young children*, considered as they appear to your senses, by *objective symptoms*, without the aid of words on the part of the patient, and how to manage them accordingly. My inquiries will almost entirely refer to the *tender age under three years*, because in proportion to the advancing age, all kinds of peculiarities in form, diagnosis and treatment, and all kinds of difficulties become less. In this task I have no predecessors, and you will find nothing of the kind in books; but I am convinced of its usefulness and of the possibility of giving the young practitioner some valuable hints and directions.

Fevers in children form a most arduous part of practice. You will have occasion to notice constantly, that as soon as a child shows the expressive symptoms of fever, the parents get uncommonly afraid and excited, and the position of the physician becomes a very difficult one. The reason of this is clear. It is the greater vehemence and obscurity of symptoms. Bethink yourself of two patients affected with the same kind and degree of fever; the one a man and the other an infant. On both you observe, without asking, a high degree of heat, great frequency of the pulse, both with great languor on their countenance, heavily moaning, and refusing food. You auscultate both, and find nothing important in the chest. So far you are on equal diagnostical terms with the man and the infant; but you feel not satisfied. That expression of languor and that moaning make you anxious, and you will now ask some questions. The man answers:—he feels no decided pain anywhere, but giddiness and heavy pressure in his forehead, fulness and pressure in the epigastrium, and bitter taste in the mouth. And now you feel satisfied and easy about the patient; you prescribe an

emetic with the fullest confidence. But suppose he could not have spoken a word; what a difference to your understanding of the case! And so you are with the infant; and yet you cannot stop there, you must endeavour therefore, by some other means of investigation, to supply the want of words.

There is reason for anxiety in these cases indeed. Strong fever is always connected with headache, and headache connected with fever in a child may appear as meningitis, whilst words might have convinced you otherwise. In the same manner, some obscure symptoms of pain in the abdomen, whilst the skin is hot and the pulse running over 140, may lead you to suspect enteritis, where an intelligent patient might have dispelled that fear. You see here the necessity of some other means of observation and diagnostical construction in order to supply the want of words.

And yet even the eruptive, and the typhoid, almost the only fevers you meet with in treatises on children's diseases, are treated, to a great extent, in a manner which supposes intelligent patients; and subjective symptoms, and other fevers are more neglected still.

My present task, therefore, is to draw your attention to those phenomena and signs, which you must detect for yourselves on the child affected with fever, who does not reflect and cannot express his sufferings; and to show you the way, how to form the diagnosis, or at least an opinion upon the case, and give you some directions for treatment.

I have not to speak here on the theory of fevers. Very generally, and with good reason, a great class of fevers is admitted, *primarily and essentially*, as *general disorders of the blood and nervous system*, which may begin as such, and run to a happy or an unhappy termination *as such*; but in the course of which also different local disorders can arise, of different importance. Even pneumonia or enteritis are sometimes preceded for a good while by fever, before they appear in their first rudiments. Our predecessors of ancient times said of similar instances;—"Febris in pulmones,—in intestina lapsa." Our present purpose is to consider fevers on children, in which fever itself, with its general disorders, plays the prominent part; but it is clear in this task, we must frequently refer to different kinds of local affections, which may be concealed under the general phenomena of the disordered blood and nervous system, and which in many cases become more important than those general febrile disorders. Therefore a treatise on fevers cannot be kept strictly separated from those concerning local affections.

There is a facility in the fact, that children are liable to the same fevers as adults; that, consequently, the knowledge we have got by the words of intelligent patients, can fill out one part of the vacuum left on the speechless child. Thus the first advice I give you for that object of practice, is, when you have to attend a child in fever, take the case up exactly in its objective symptoms, then recollect or imagine one similar in a grown-up patient, after which make a sort of application of those symptoms of the latter, which you have or might have got by his words, to the illustration of the

former. I will explain myself by an example. Suppose you have before you a little child under heavy fever since yesterday, his skin very hot, the pulse about 150, the respiration very quick, accompanied by slight moaning, which appears to be short, as if cut off; the child lies quietly, with some expression of languor on his countenance, the abdomen a little tense. You cause it to be lifted up in the arms of the mother, examine every part of the body, use auscultation and percussion, with a negative result; languor and a plaintive moaning become more apparent. There must be pain somewhere, you say, but you know not where. You imagine, now, a similar group of symptoms on an adult. You might have requested him to make a deep inspiration, and upon trying to do so, he might have felt checked by pain in one side of the chest. Now you conjecture, perhaps, this may be the case with the child; but how will you ascertain it? You must find means to make him more deeply inspire. Under similar circumstances I have been led to lay my hand across the lower part of the belly, and push in a gentle and gradual way the viscera towards the diaphragm up into the chest, in order to restrict that cavity and constrain the child to forcible inspirations, which I could not obtain by words. In fact, in doing so, I obtained what I wanted; I saw the child could not freely inspire; he became angry under my pressing, and began to cry, but it appeared at once that even crying was precluded by pain. And now, by some more close examination by auscultation, together with appropriate positions and movements performed with the child, I could even conjecture in which side was the seat of pain. And then, regarding the degree of heat and pulse in proportion to the visible degree of pain in the chest, without râles, without dullness, only the second day after the fever had commenced, I was allowed to conjecture rheumatic fever with pleurodynia.

This may serve only as an example of a possibility. Your comparison and induction (different in different cases) will not always come to a clear conclusion on the child, but I believe you will find useful that little mental operation in your diagnostic exertions.

The relation of children to fever, however, differs in many points from that of grown-up people. Some species are at certain periods of childhood more, others less frequent; or their intensity and effects are different. Thus eruptive fevers are seldom met with before the fourth month; they are the most frequent between the seventh and twelfth year. Abdominal typhus is rare before the eighth, or at least not characterised in the same degree on the intestines, as from the eighth year upwards. Intermitents and bilious fever, even during severe epidemics, (as I had opportunity to witness some,) seldom attack tender infants; under the third month I scarcely remember one case of the former, and under a year and a half none of the latter. Again, we observe just in the most tender age a kind of secondary asthenic fever, which in this form is rare at a more advanced period of life. In general the course of any high fever is in children more rapid, towards recovery or death; remissions, however, are more salient, and very

common in young children. And there are many other peculiarities in the course, character of reaction, forms, and complications.

The nature, stage, and complications of a fever in a little child, we recognise merely by objective symptoms. The most apparent, constant, and therefore important of these are, *abnormal frequency of the pulse, and abnormal heat of the skin*. Proportional to the degree of these, we observe a greater frequency of the respiratory acts, lassitude, and others, less constant, or less accessible to our senses.

If we ask, which degree of frequency of the pulse, and which of heat, form the limit between simple excitement (erethism) and fever? This question it is impossible to exactly answer. A pulse of 120, 130, or more, may be present for some time in a healthy infant, whilst that of 90 may be, in an elder child, a febrile pulse. In general you must value the frequency with regard to the age. On average terms the pulse is more frequent in proportion to the more tender age; from about 5 to 25 more pulsations than in adults. As to the skin, we observe generally a little lower temperature in the first few weeks after birth, then it appears commonly higher than in mature age, but never attains in fever that high degree of *dry heat* which imparts to our hands almost a *burning* sensation before about the seventh or eighth year. The skin of young children maintains sometimes, even in high fever, a degree of softness.

According to the great sensibility and mobility of the tender age, both heat and pulse vary more than in adults in short spaces of time; slight causes are sufficient to increase both much higher within the limits of health, but this very sensibility will make them also more liable to be thrown into real febrile disorder. Matters connected with life do not allow absolute limits and terms. I should say, a child under three years can be considered to be in fever if, under ordinary circumstances, and in prolonged quiet position, its pulse is above 100, and at the same time the skin feels uncommonly hot.

The whole *objective appearance of an attack of primary fever*, I would characterise as follows:—For a few hours, sometimes even days, the child appeared to be less cheerful and lively than usual; persons accustomed to see it will have noticed a change in his countenance, and a degree of languor; sweet and quiet temperaments show restlessness and irritability; sleepiness, but no tranquil sleep. Elder children are desirous to be put into their bed, but infants and young children generally will not remain there quietly, and must be taken up in the arms.

These symptoms precede, in some cases, only very shortly, the stage of cold, if it has to come; in fact, however, *rigor* is by far not so common a symptom at the commencement of fevers in children as in grown-up people; and *shivering*, even in intermitents, (of which I have observed great epidemics,) is exceedingly rare under one year of age. Under the fourth month I have never seen it; if it takes place then, we observe the child slightly tremble, when it appears to draw the

limbs close to its body; the nails of its fingers become blue, the countenance pale and collapsed, bluish about the eyelids, breathing quicker and more audible, the pulse augments to about 95, 100, or more, and rather small. Vomiting is not unfrequent at that time; also a little dry superficial coughing, is not rare.

This *stage of cold*, if present at all, may continue for some minutes, and in little children rarely longer than ten or twenty; in older, in rare instances, an hour or longer, during which the skin feels cool, or at least less warm than usual, and that of the nose and feet decidedly cool. The skin does not, in general, feel so rough as in adults. During that time the majority of nurslings do not take the breast, or only for a short time.

After that group of symptoms, more or less complete, most generally without perceptible cold, and frequently only limited to languor and low spirits, the skin becomes gradually hot over the whole body; frequently first on the epigastrium, in some cases rather on the front, but it extends then to the hands and feet. The skin has lost its softness, but becomes not so dry as in older children or adults. The pulse increases to 140, 160, or more, particularly in young infants, and continues hard, and rather small; distinctions which, however, we cannot easily make in very young infants, their arteries being too small for it. In the same proportion the respiration gets more quick, frequent and noisy. In most cases heavy sleep befalls the child, but it is restless, with occasional loud moaning, and starting up. The eyes are shut, or half shut, with occasional or constant *perpendicular wrinkles* on the front; the mouth performs frequently a kind of sucking, or other unconscious movement; the countenance becomes flushed and turgid; increase of thirst, which in infants is manifested by frequent desire of, and avidity in, sucking; the tongue and cavity of the mouth may now become dryer than usual, but not always, and not to such a degree as in grown-up people; nor must you expect in them that thick, yellow, or brown fur on the tongue; no urine, or very scanty, and leaving some stain on the linen; the bowels more frequently confined.

Dry heat may last, or even increase, for some hours, seldom longer than twenty-four, without some change in its intensity. In infants and young children vomiting or eclampsy are not unfrequent during that stage, and under ordinary circumstances, and in good constitutions, seldom dangerous, but always very alarming to the family. Febrile headache may be considered as frequently their source. Intermittent paroxysms cause more frequently eclampsy than any other kind of fever.

As I have before said, in almost all kinds of continued fever, in young infants, the stage of heat comes on without previous, or at least without perceptible rigor. In elder children we observe sometimes in the beginning, cold (shivering) and heat alternating for some time, like as in adults, and then passing to the full stage of heat.

Now this description of fever, as far as it at present goes, (to the stage of dry heat,) varies very little as to the principal symptoms; but in its further stages these will present great differences.

In almost all favourable cases, after a certain time of dry heat, the skin becomes softer, less hot, and moisture appears over it, increasing to more or less decided perspiration, under which the pulse becomes less frequent and more expanded, signs of headache and languor disappear, and the child manifests in aspect and movements a gradual relief. *Sweat*, so profuse as we notice it so commonly in adults, is again rare in tender infancy.

The practitioner generally is requested to see the child in its stage of heat. In these instances your visit must not be a short one. Remain for some time, (and in a proper position,) the quiet careful observer of the child. If it be asleep, observe for awhile its position, how it rests, how it breathes, and its countenance; touch gently the pulse; look at and touch the skin; and if you find all the symptoms in harmony, and nothing salient, perhaps you would be wishful not to disturb it at that time. Occasional moaning during sleep in fever, is, in general, of no importance. But continued moaning, plaintive, or of a heavy kind, with occasional starting, usually frighten the parents. Under these circumstances, if you wish to give an opinion, and to prescribe something, you must cause the child to be taken up in the arms, and observe it also when completely awake. Frequently you will find it to be better when you see it awake, than it appeared to you when asleep. In general, during the height of heat, infants lie with their eyes shut, and not seldom show even difficulty in opening them when we make them awake. The moment when it is taken up, watch it most closely, and observe it again for a good while in a quiet position, from a distance; notice if perpendicular wrinkles on the forehead appear; then cause it to be put in various positions, its body and limbs to be variously bent and moved; explore the chest by ear and fingers, and use all that minute care and means of investigation which I have exposed in a former lecture on the *examination of a child*. In all cases of a primary paroxysm, you must closely observe the skin, eyes, eyelids, nose, mouth, and neck, the latter by careful touch; and then let the child drink in your presence, and observe the mode of deglutition; these are parts which, in the fevers of children, frequently manifest some slight signs indicative of the future character of the malady. Some slight sneezing may be, under circumstances, a precious sign to you, and in relation with others at that early stage of fever, allow you to form an opinion of the case.

I will not here spend any time in exposing the manner how to ask and value the mother's account of the former health of the child, the cause and commencement of its present ailment, and how much more minutely you must investigate the urine—as it appears on the linen, fresh or dry—and other excreted liquids; but supposing all that to be well accomplished, I beg to draw your attention to a single kind of comparative process relating to the most salient objective symptoms.

Consider the *mutual relation and proportion* of the following treble set of *symptoms*:—Heat and dryness of the skin; frequency and strength of the pulse; bearing

of the head, and languor of the countenance. Suppose the child is before you in the arms of the mother. You see it lays languidly its head on the shoulders; the eyes look languid, frequently half shut, and the child is continually moaning. This you will say is a heavy appearance. But you will be less alarmed if you find the skin very hot and a little dry, and the pulse between 130 and 160, just because there is what we may call a good proportion between these symptoms. An adult, under the same circumstances, might have his skin more dry, but his pulse only about 110 or 120; he would complain of headache, and, when sitting upright, of some giddiness. As to the child, you may express the opinion that it is under considerable fever, but that its constitution seems to resist it well. Suppose, however, you should find the child with the same expression of heaviness of the head, languor, and moaning, as mentioned, but the temperature of the skin lower, and the pulse above 170. Under this proportion and mutual relation of the same symptoms, your opinion should be less favourable than the above; you might say that the child is seriously affected by *that* fever; or, the fever has an asthenic character. This, however, will scarcely ever happen as early as within the first twenty-four hours.

I here suppose always cases of fever, where you can not detect any such local affections which are more important than those general disorders of which the fever itself consists. Under these circumstances, at your first call, and within the first twenty-four hours since the outbreak, you must not be in a hurry with your opinion and medicinal interference; because between twenty-four and thirty-six hours from the outbreak, in the majority, you will see one or other of the following changes, which will throw more light upon the case:—Perspiration, vomiting, or diarrhoea, with some influence upon the fever; remission or intermission, and a new exacerbation of paroxysm; or some local affection coming forth.

Catarrhal, rheumatic, and true inflammatory affections, if they have to occur in the course of a primary fever of a child, almost constantly offer to a clever observer their first rudiments before twenty-four hours are over. Those of a secondary kind and bad character may appear under a further stage of it,—*f. e.*, ulcerous angina.

Acute exanthemata in little children announce themselves also within the mentioned time by some change on the skin—an apparent degree of injection, recognisable by drawing, with some pressure, our finger over it. But, again, sometimes the prodroma protract their ambiguous and puzzling appearance, even as long as three or four days; but if the fever is *high and unre-mitted*, you may regard as an average term of the eruption, for that age, about thirty-six hours from the beginning of its present and uninterrupted paroxysm. I say from the present, because in those cases where the eruption appears several days, even a week or more, after the so-called invasion, the fever will not maintain that continuous height of symptoms, of the stage of heat, as we have previously described it. There are alient remissions in similar cases.

Some conjecture upon the nature of the fever we derive also from the epidemical genius of the season and place.

Asthenic or typhoid fevers, in the majority of cases, can scarcely be recognised before the third or fourth day; and typhus is, even at that time, and in children above the eighth year, frequently ambiguous. Influenza, however, which in young children and infants frequently appears as an *asthenic* bronchio-catarrhal fever, often shows that character already between twenty-four and forty-eight hours. The secondary asthenic fevers (so particularly proper to young children, of which I will speak more in one of the following lectures), can also be guessed sometimes as early as that, but rarely develope themselves clearly before the third or fourth day.

As another point useful to the formation of your opinion as to the dangerous or favourable character of a recently-developed fever, is the *period of prodroma*, which preceded its formal outbreak. In general I have found that prodroma which run a day or two longer before the outbreak, show a more severe character of the fever than shortly-lasting prodroma, or when the fever bursts out more suddenly.

The parents, anxious to get your opinion with regard to the character and danger of the case, generally incline to denounce a fault in diet, or cold, as its cause. You must not yield too easily to similar suppositions. In young children and infants, of healthy and good constitution, indigestion most generally causes vomiting, which makes the case clear. Sudden attacks of high fever in general arise from atmospheric or epidemical causes.

Finally, it scarcely need be mentioned that your prognostical opinion will be led also by the constitution and other circumstances of the child.

The mentioned anxiety of parents, and the questions they ask you at your first call, in cases of *violent fever*, concern very commonly meningitis; and the great majority of practitioners, by the same fear, resort to leeching immediately at their first call; though I am satisfied, if they had waited some hours longer, in ninety out of one hundred similar cases it would have become manifest that there was no necessity for it. It is febrile headache, as I mentioned, which causes that alarm, so much the more if convulsions had appeared. In this way very often the good course of the fever becomes troubled, and a favourable crisis delayed; this is, in particular, the case with weak and delicate children, who are the most liable to febrile troubles and headache, but the least liable to active congestions or meningitis.

As to a transient fit of eclampsy at the height of recently-developed fever, we must value the fact that strong fever is connected with headache and disordered spinal innervation, by which latter, in young children, eclampsy may easily be induced. I have shown it to hundreds of those who attended my courses in the Children's Hospital of Pesth, that in the majority of children who died by convulsion, dissection could not prove the anatomical character even of active conges-

tion, still less of meningitis. The same is the result of the extensive pathological inquiries of Dr. Bednar, published in Vienna in 1851.

These reflections I adduce only in order to counteract a little of that fear, too general, of meningitis in children during the stage of febrile heat. The alarming aspect of febrile headache in a speechless child, however, cannot be denied; I will, therefore, consider that subject, and some others connected with fever, more closely in my next lecture.

ON THE DIAGNOSIS OF CHRONIC OVARIAN TUMOURS.

By E. J. TILT, M.D.,

Senior Physician to the Farringdon General Dispensary and Lying-in Charity, and to the Paddington Free Dispensary for Diseases of Women and Children.

"Hydrops ovariorum ut plurimum steriles annosaeque mulieres occupat difficilius cognoscitur et vix sine sectio cadavere."—Boerhaave (*Aph.* 1223.)

(a) *Ovarian Tumours may be confounded with Tumours of the Unimpregnated Womb.*

RETROVERSION and retroflexion of the womb have been mistaken for incipient ovarian tumours, fallen into the recto-vaginal pouch, or confined there by false membranes. On examining, by the vagina, a patient suffering in this way, we may find a circumscribed tumour at the posterior portion of the vagina, painful on pressure, and resembling the fundus of the womb; but on a more careful examination, the os uteri will be found in its proper position looking backwards, the body of the uterus forwards. The mobility of the tumour, by the uterine sound previously introduced, will show whether or not it be uterine.

Retroflexion of the womb is more likely to simulate incipient ovarian cysts; for, as in this affection the fundus uteri is thrown back upon itself like the belly of a retort, while the os uteri remains in its natural position, the finger feels a tumour directly behind it, between the rectum and the vagina, but here again the uterine sound soon clears away any doubt that may have arisen, for it will be found that the concavity of the instrument will be obliged to pass backwards, following the course of the cavity of the womb, and through the walls of the tumour; the point of the instrument may sometimes be felt by the finger placed in the vagina. By a careful manipulation the tumour may be made to disappear and to re-appear so often as it is restored to its natural position, or again directed from it by the sound.

(b) *Ovarian Tumours may be confounded with Abscess of the Walls of the Womb.*

Case.—Some years since Professor Recamier was consulted by a medical man for his wife, who had long suffered from what was called ovarian dropsy. On making a very careful examination, Recamier discovered a round tumour about the size of a pigeon's egg,

situated between the rectum and the uterus. On exploring the rectum with the index of the left hand, while that of the right remained in the neck of the womb, more than usually dilated, he felt fluctuation, and as the pus seemed nearest to the posterior wall of the neck of the uterus, Recamier determined on making an incision there. To perform this operation, he placed the index of the left hand in the neck of the uterus, and guiding a convex bistoury on the pulp of this finger, he plunged the extremity of the bistoury into the abscess, a few teaspoonsful of pus came out, and to facilitate its egress he enlarged the inferior angle of the wound, by completely cutting through the posterior lip of the os uteri, the index of the left hand placed in the rectum serving to guide the bistoury, and prevented too deep an incision. During the following day a small quantity of pus was voided. Frequent injections were made, and the patient soon got well. This case shows how to detect and to cure similar instances of disease.

(c) *Ovarian Tumours may be confounded with Abscess of the Cavity of the Womb.*

Husson presented to the Anatomical Society of Paris a case of this description, the neck of the womb was completely obliterated, and its dilated cavity contained two tumblers of pus. Maisonneuve saw a similar case in a woman who died from cholera; and Dr. Reignier has repeatedly observed the same appearances in the old women of the Salpêtrière—the asylum for aged women in Paris. In Husson's case, the woman had experienced no symptoms, but some of Dr. Reignier's patients were troubled with bearing down pains. We admit that a case of that description might be taken for an ovarian tumour, and then, if a careful recto-vaginal examination were made, the swelling would be referred to the womb. If, on making a speculum examination, the womb were found obliterated, the presumption would pass into conviction; and if not, then the uterine sound would show whether the womb was normal and the tumour ovarian. The rarity of the case must be borne in mind.

(d) *Ovarian Cysts may be Confounded with Hydro-metra, or a Collection of Water in the Womb*, and we do not doubt but that some of the cases described as cases of spontaneous cure of ovarian cysts are to be referred to the rupture of such uterine tumours. The distension of the impregnated uterus by an aqueous liquid has been lately contested by Nægele and by Stoltz, although it is difficult to see why the mucous surface of the womb should not secrete a large quantity of limpid fluid, as well as the mucous surfaces of the maxillary and frontal sinuses. The disease has been too well described by Ferrelas (*Patho. Liv. vi., chap. 15*), by Mauriceau (*Traité des Maladies des Femmes Grosses*, tom. i., p. 74), by Lisfranc (*Clinique*, tom. iii., p. 346), to be thus denied. Dr. Storrey has also described a case (*Haye's Journal*, 1850). It will not do to say that the aqueous discharge comes from the ovary, because Vesalsus, Blank, and Nicolai have opened women who had long suffered from this disorder, and found the womb containing 84lbs. and even 180lbs. of

serum. This disorder is accompanied by the symptoms of pregnancy, and is generally considered such until after the ninth month of its duration. Then it is generally regarded as ovarian. In a case carefully related by Blegny (*Journ. de Médecine*, tom. ii., p. 97,) it was allowed to exist for twelve years, and the noble lady subject to this infirmity was only delivered from it by the violent concussion of coughing, by which means a large quantity of water was discharged.

After fully ascertaining the impossibility of the womb being distended by a child, it would be well to imitate Lisfranc, who, in one of his cases introduced a sound into the womb, and cured the patient in a month. Cruveilhier says, that in the few cases of this description that he had met with the disease was always taken for pregnancy, and the mistake only found out by the evacuation of the water. We ourselves have been similarly deceived, as in the following instance:—A lady, 25 years of age, and married three years, was said to be affected with ovarian disease, and consulted us for that disorder. She complained of swelling of the abdomen, uterine pains, and slight leucorrhœa. Her breasts were swollen and painful, the nipples were surrounded by a dark circle, and a yellowish creamy substance came from them. The catamenia had desisted for three months. Suspecting pregnancy or an uterine affection, we examined her, and were confirmed in our diagnosis by a dilated orifice, and a softening similar to what is met with at the third month of pregnancy. On making a speculum examination, the vagina was more livid than in an unimpregnated woman, and the os uteri was similar to what it should be in the first months of pregnancy. We pronounced the patient to be in the family way; but unsatisfied with our report, she consulted another doctor, who considered her case to be one of inflammatory granulation of the os uteri. He cauterized the cavity of the neck with nitrate of silver; but the night after the second cauterization the lady was surprised at finding herself wet, and on placing herself on the commode, she passed (without making urine) two pints of clear water, "similar," said her mother, "to the bursting of waters in a confinement." For two days did this water continue dribbling from her, when the swelling of the abdomen disappeared, all other symptoms vanished, and the catamenia reappeared two months after. Thus the patient had neither ovarian dropsy, as was at first believed, nor uterine inflammation, as was afterwards stated; neither was she pregnant, as we imagined. Our diagnosis was founded on rational grounds; and the error could only have been made clear by passing the uterine sound into the womb, which would have been an *unwarrantable* proceeding; for as such cases are extremely rare, and as pregnancy is an event of every-day occurrence, the risk of abortion would have been too great. In this case, therefore, the patient owed her recovery to an error of diagnosis.

(c) *Ovarian Tumours have been Confounded with Cystic Tumours in the Substance of the Uterus.*

In the Museum of the College of Surgeons of England there is a preparation removed from a patient

in whom this mistake took place; (Home 980, uterus 23,) it displays a portion of the uterus in which a large encysted tumour had formed. The patient had been twice tapped, and the cyst emptied. By means of the sound such a tumour might have been shown to be uterine, before it attained to a considerable size, or after it had been emptied, but at other times the possibility of distinguishing it from an ovarian cyst would be very great, if not impossible.

(f) *Ovarian Tumours may be Confounded with the Uterus Distended by the Menstrual Secretion.*

Mr. Benjamin Travers, jun., witnessed such a case in St. Thomas's Hospital, under the late Dr. Williams. Examination per vaginam detected a fluctuating tumour, which was freely opened with an abscess-lancet, and a large wash-hand basin was filled with the retained menstrual fluid. The patient was in bad health, and presented general symptoms which led to the belief that the tumour was ovarian. Such a case Mr. Travers thought might again be mistaken for ovarian dropsy.

Roussell mentions a similar case, where all the symptoms of pregnancy were found, and only dispelled at the ninth month by a copious discharge of dark blood. A careful examination, corroborated by the fact of the patient's age, and by the history of the case, would, however, easily permit of a correct diagnosis. It may be well also to bear in mind, that the uterus, distended by retained menses, is not always regularly developed, but may increase to the right or the left, and give that obscure perception of fluctuation which is frequently found in a malignant mass. On each side of the central tumour may also be found smaller elongated tumours, formed by proportionally-distended oviducts, with obliterated abdominal ends, as in the case related by Dr. Jackson, in the *American Journal of Medical Sciences*.

(g) *Ovarian Tumours may be Confounded with an Accumulation of Gas in the Womb.*

Mauriceau, Schmitt, Lamotte, M. Lefevre, and many other authors, have seen examples of this singular occurrence. In Mauriceau's case the patient was 50, thought herself pregnant, had prepared every thing, when her hopes of progeny vanished in wind. The obliteration of the os uteri on the one side, and the clear sound furnished by the distended womb, will, we trust, enable the practitioner to prevent a woman in future giving so much trouble to herself, and so much amusement to her neighbours.

Although it be denied by Nægele and Stoltz, that the unimpregnated womb can be distended by gas, the fact is admitted by modern practitioners; by Peter Franck, ("Med. Pract.,) by Columbat de L'Isere, ("Traité des Maladies des Femmes, tom. ij., p. 781,) and lately by Dr. Teissier, of Lyons, (*Gazette Med. de Paris*, Jan., 1844.) In these cases menstruation ceased, the patients were thought pregnant, one of them even said she felt the movement of the child, but after the noisy expulsion of foetid air by the vulva, the symptoms of pregnancy disappeared. Why should not the mucous membrane of

the uterus sometimes secrete air, as well as the bladder or the intestines? Why should it not be retained if the surface of the womb is agglutinated?

(b) *Ovarian Tumours may be mistaken for Uterine Fibrous Tumours.*

This mistake is much more liable to occur than any of the preceding, because the frequency of such tumours is great. Operators have often been deceived by these tumours, for we find that Messrs. Lizar, Heath, Otter, and Atlee have operated for ovarian disease, and only found an uterine tumour; and when they are pediculated, and thus easily moved, and central, as are ovarian tumours, it is difficult not to be mistaken. The absence of fluctuation, the hardness of the tumour, the very gradual progress of the disease, may indeed allow one to affirm that the tumour is solid; but were it not for the uterine sound, it would be difficult to affirm that it is not ovarian.

If we find that the uterine sound passes, as it were, into the morbid mass, if there is no possibility of separating the womb from the tumour, and if every movement given to the tumour conveys similar movements to the sound, we may consider the tumour uterine; but if we find the uterus small, and moveable, if the sound passes anteriorly to the tumour, and can be separated from it, and when thrown upon the rectum it appears healthy, then we may confidently affirm the tumour to be ovarian. The cavity of the womb may be lengthened, and the sound will indicate the modification of structure; but although the sound may only penetrate the womb to its normal depth, or two inches and a half, still the uterus may not be normal, for its enlarged cavity may be filled with a fibrous tumour, as in Dr. Atlee's fourth case.

Case.—In Dr. Simpson's ward at the Royal Infirmary, in Edinburgh, we saw a woman with a considerable enlargement of the belly, occasioned by a tumour, which had all the appearance of being ovarian, for it was central, moveable, and round. Such would have been the diagnosis of most medical men; but Dr. Simpson passed the sound seven or eight inches, and made us feel its extremity high up on one side of the tumour, whose nature and seat it thus indicated as uterine.

Such is the value of "a bent wire," when bent by the hand of genius, and it will long perpetuate the memory of its originator; but this instrument may still sometimes deceive us, and cause us to take an ovarian tumour for one of uterine origin, as in the following case related by Mr. S. Lee:—

Case.—A patient presented herself with an abdominal swelling on the right side, hard, and without fluctuation, not at all moveable, but it could be traced down into the pelvis; it had been a considerable time in its formation. The examination per vaginam discovered that the brim of the pelvis was occupied by a solid tumour; a small nodule was felt rather in front of the centre of the pelvic cavity, in which was the os uteri. The sound

passed upwards and forwards nearly four inches; it moved with difficulty, as through a cavity, the sides of which were much compressed. This examination was made in December.

Here, then, you have every characteristic of a fibrous tumour in the posterior walls of the uterus. The cavity is elongated, the uterus is fixed by the brim of the pelvis, and the tumour in the abdomen is hard and smooth, possessing no fluctuation. The tumour now rapidly increased, and in the January following had occupied the whole cavity of the abdomen. There was then distinct fluctuation in particular parts, and this fact disclosed to us the real nature of the case, viz., that it was a multilocular cyst, complicated with much solid matter. The reasoning from these symptoms was correct, although they were afterwards found peculiarly complicated; for instance, the uterus was quite healthy, and unconnected with the tumour, but the tumour had so elongated the left corner of its body, and so elevated it, that the uterine sound passed into the cavity thus formed, and the tumour itself contained such a large quantity of solid matter, that it pressed so strongly the uterus between itself and the pubes, as to cause it to become fixed and immoveable, consequently leading us to suppose it to be a fibrous tumour.

11, York Street, Portman Square.

[To be continued.]

CASE OF INVERSIO UTERI.

By CHARLES MARSHALL, Esq., WOODBRIDGE.

Read at the Suffolk Branch Meeting, July 25, 1852.

THE following rare and interesting case of inversio uteri recently occurred in my practice:—I was called to Mrs. D., aged 38, at six, p.m., on the 14th of May, in labour with her sixth child, having previously attended her on five similar occasions. The labour was in every respect quite natural; she was delivered twenty minutes before eleven the same evening, the placenta was retained till ten minutes past eleven, or half-an-hour after the expulsion of the child; there was a slight pain at this time, and on introducing my finger into the vagina, I could distinctly feel the placenta lying there, and the slightest traction caused the whole to be expelled. Up to this period nothing occurred to cause either myself or patient the least alarm; whilst, however, I was preparing a bandage to apply to the abdomen, the patient called out, that "the whole of her body was coming out, and that she was dying." I immediately hastened to her side and found the skin covered with a cold perspiration, no pulsation perceptible at the wrist, and gasping for breath. Brandy happened to be at hand, a quantity of which I managed to pour down her throat. There was little *external* hæmorrhage, and I therefore concluded these alarming symptoms resulted from *internal* hæmorrhage. On attempting to

pass my hand into the pelvis, I found the vagina blocked up by a large mass, which was in fact the *uterus completely inverted*; having never seen anything approaching to a similar case, I was at a loss how to act best for the safety of my patient. I had ordered the husband to call in one of my brother practitioners, and Mr. Jones was kindly in attendance in a very few minutes, whose account of the case I subjoin:—

"I saw Mrs. D. at forty minutes past eleven, P.M., found her pulseless, with her eyes turned up, and apparently sinking. I instantly placed her head in a depending position; upon applying my hand to the abdomen I missed the uterine tumour, and immediately suspected the uterus was inverted, which, upon examination, I found to be the case. My first impulse was to apply pressure to the most depending point, counter pressure being used with my right hand upon the abdomen, (where I could distinctly feel the os behind the pubes,) this produced no effect; I then grasped the uterus firmly for a short time, with the view of diminishing its size, and then applying the back of my fingers half closed to the *upper and posterior part* of the uterus, I was enabled gradually to return the part nearest the os, and when about half its volume was reduced, the fundus went up with a jerk."

A dose of ergot with brandy was now administered, the patient having previously swallowed half-a-pint of brandy in little more than a quarter of an hour; the pulse at the wrist became perceptible; the uterus contracted; a full dose of tincture of opium was given, and no untoward symptom has since occurred. I strictly prohibited Mrs. D. from leaving her bed till after the third week. I have seen her this day, five weeks after her confinement, she could walk across the room without any symptom of prolapsus uteri, and quite as well as in the same period after her previous confinements.

I consider the alarming symptoms I before alluded to, after the expulsion of the placenta, to have been caused by the second shock the nervous system sustained from such an event as *inversio uteri*, and not from *hæmorrhage*, which was by *no means excessive*.

Benjamin Page applied to me, stating that he had long suffered from "sore mouth," the fœtor of which was intolerable, the whole mucous membrane of the mouth was highly inflamed, tongue swollen, and its point elevated by enlarged sublingual glands; at the bottom of a puffy swelling of the mucous covering of the right gland, was a small yellow spot, presenting the appearance of an ulcer, but on touching it with a probe, I was satisfied that it was a calculus. A free incision was made over it, and this calculus extracted. The left sublingual gland being even larger than the right, highly inflamed but not ulcerated, I made a free deep incision over it, the bistoury grated against a hard substance, which was for awhile, however, obscured by hæmorrhage, but on passing a probe into the wound, I readily picked out the calculus, measuring three-fourths of an inch in length, and nearly an inch and a half in circumference. The wounds healed kindly, and in a few days the man was perfectly well.

ON SEVERE INJURY OF THE KNEE-JOINT.

THE following case is one of practical interest, establishing the fact contended for by modern surgery, that severe injuries to large joints, with even extensive penetrating wounds into their cavities, do not invariably require amputation.

John Rumsey, aged 37 years, while mowing grass, March 8th, 1849, fell with his bent knee on the edge of his scythe, which divided the whole anterior part of the joint, the ligamentum patellæ, with the external and internal lateral ligaments. To all appearance the leg hung by the integument on the back of the limb, the posterior ligaments, and flexor tendons. The patella was retracted, and a breadth of four fingers could be readily inserted between the head of the tibia and condyles of the femur; much blood was lost. Being from home, my partner, Mr. Jarmain attended, and the question of immediate amputation suggested itself, but being without assistance, he contented himself by placing the limb in as comfortable a position as possible till my return, with the heel well raised, and he brought the edges of the wound together with sutures, having previously freed them and the joint from coagula and all extraneous matters.

On visiting the case some hours after, I found him free from pain, the limb comfortable, and no constitutional disturbance present. All went on *thus* prosperously for three days, when heat and pain with profuse discharge, rendered it necessary to remove the dressings, the edges of the wound retracted, the sutures were sloughed out, the whole interior of the joint was exposed, and the fearful extent of the wound was fully apparent; extensive abscesses formed in the course of the vastus externus and biceps muscles, constitutional symptoms of disturbance set in—rigors, irritative fever, and profuse night sweats. These symptoms, however, gradually yielded to treatment, and after a confinement to his bed for fourteen weeks, to his house for twenty-six weeks, and an inability to return to his usual employment of

CASES IN PRIVATE PRACTICE.

By ROBERT MARTIN, Esq., HOLBROOK.

Read before the Suffolk Branch Meeting, held on the 25th of July, 1852.

CASE OF CALCULARY DEPOSITS IN THE EXCRETORY DUCTS OF THE SUBLINGUAL GLANDS.

RANULA is by no means an uncommon disease of the sublingual glands, and must have fallen under the observation of many present, but the case I am about, (as briefly as possible) to lay before you, the complete obstruction of the excretory ducts on both sides the *froenum linguæ* by calculary deposit, is I believe somewhat rare. I have never before seen an instance of it in my practice, which extends over a period of thirty-seven years.

eighteen months, he now again maintains a large family by his labour as a husbandman.

It will be noticed, that although great pains were taken during the progress of ankylosis to keep the leg straight, yet the inflammation and consequent shortening of the biceps, flexor, cruris, and outer head of the gastrocnemius, have produced a necessity in progression for eversion of the foot.

Although aware that Dr. Rhea Barton and Dr. Gibson, both of Philadelphia, are reported to have successfully operated for the removal of ankylosis of the knee-joint, I am too well satisfied with the result of this case to contemplate further interference.

Hospital Reports.

WEST NORFOLK AND LYNN HOSPITAL.

CASES ADMITTED UNDER THE CARE OF CHARLES COTTON, M.D., F.R.C.S., SENIOR SURGEON TO THE HOSPITAL.

Stone in the Bladder—Lithotriety—Cure.

WILLIAM KEMP, labourer, aged 64 years, admitted November 21st, 1848, with symptoms of stone of several month's duration. Catheter passed, and a moderate sized calculus detected.

Nov. 24th.—Bladder injected and screw lithotrite introduced. The stone was readily seized and easily crushed, the index of the instrument marking 9-12ths, and yielding to 5-12ths on the application of the screw. On withdrawing the lithotrite the blades of the forceps were found densely impacted with triple phosphatic fragments. To keep his bed and have constant hot fomentations to pubic and perineal regions. Anodyne draught directly. Slop diet; barley, gum, or linseed mucilage for drink.

27th.—Several portions of detritus have come away during micturition, giving but little inconvenience. Catheter-forceps introduced, and some more fragments withdrawn. Anodyne draught given and fomentations repeated.

30th.—Muco-purulent and calculous deposit in the urine; "feels a little cutting on making water, and rather weak; but is otherwise quite well."—R. Bals. Copaibæ, m. xx.; Liq. Potassæ, m. x.; Mucil. Acaciæ, oz., iss. Ter die sum. Full diet and gin.

December 5th.—Made out-patient.

19th.—No difficulty attends micturition; urine clear; bladder carefully explored, and a catheter-scoop reintroduced, but not a particle of calculous matter discovered. Anodyne draught and hot fomentations. To remain an in-door patient a day or two. Repetatur mist. bis terve die.

30th.—Discharged cured.

Stone in the Bladder—Eight small Calculi Removed by Catheter-Forceps—Cure.

Samuel Fisher, farm labourer, aged 71 years. Admitted August 14th, 1849. Had suffered severely

the last nine months, from pain referred to the region of the bladder, and great difficulty at times in making water, aggravated by walking, or riding in any uneasy vehicle. By sounding with the finger in the rectum, several small calculi were detected. The urinary passages were found in a highly sensitive condition, and the patient complained bitterly of the examination. To be immediately put to bed, to have flannels wrung out of hot water to the pubis, frequently renewed.—R. Extr. Hyoscyami, gr. ij.; Liq. Potassæ, m. xx.; Infusi Diosmæ., oz. ij. M. Fiat haust stat. sum. et repetatur ter in die. Bread and milk or broth diet, and linseed decoction *ad libitum*.

18th.—Better, irritation subsided; bladder injected with warm water and catheter-forceps introduced. A small lithate of ammonia calculus the size of a horse-bean, with its shell crushed, was then withdrawn between the blades of the instrument. Scoop reintroduced, bladder injected through it and a second similar calculus extracted. Hot water applications to the perineum. No alteration in diet or medicine.

19th.—No unfavourable symptom; some soreness and smarting; has passed urine freely, mixed with a few calculous particles and grit.

24th.—Three pisiform calculi removed by means of catheter-scoop.

September 1st.—Three other small calculi, in all eight, extracted with the catheter-scoop.

2nd.—No material ailment beyond a trifling soreness. Urine thick and scanty. Full diet and porter.—R. Tinct. Ferri Sesquichlorid., m. x.; Tinct. Hyos., m. xx.; Decoct. Pareiræ, oz. ij. Fiat haust. ter die sumendus.

7th.—Feels quite well and passes water without discomfort. Bladder explored; no other calculus detected.

10th.—Discharged.

Remarks.—The above cases (selected from upwards of a dozen occurring in hospital and private practice,) treated by the lithotriety or sliding catheter-forceps, without a single accident attending the operation, may be contrasted with that of Stebbing, reported in the *Provincial Medical and Surgical Journal*, of February, 1846, a patient in whom the kidneys were found to be mere cysts, and where death took place on the 6th day, after a few "irresistible attempts" to break up a large oxalate calculus.

The case of Fisher is destitute of any particular practical interest beyond that of showing the value of the sliding catheter-forceps, (invented by Mr. Weiss,) in cases where there is good reason to believe that the calculus is of small size, or when, after crushing, it is so desirable to prevent the chance of a fragment remaining to form a future nucleus. Indeed nothing can be more simple than the use of this instrument in cases to which it is especially applicable, if the following method be observed:—The injection of the bladder having been completed in the usual manner, and the stopcock-catheter withdrawn, the catheter-forceps, *plugged*, are to be introduced in its place, and the bladder fairly entered, the convexity of the fixed blade is then to be directed towards its posterior part, whilst the

moveable blade is withdrawn by the thumb, and the injection allowed to escape, during which the blades of the forceps must be gently closed and separated, from time to time, when the rush of the injection through the instrument, and the contraction of the bladder will almost surely force any foreign body within its grasp; of course especial care must be taken to dislodge with the stilet any unyielding calculus or fragment which cannot be withdrawn without over-stretching and injury to the urinary canal, for although instances have been witnessed of the extraction of incredible-sized calculi or fragments by this instrument, without any important casualty, others, again, have been observed in which such practice has been attended by miserable suffering and the most disastrous consequences.

[To be continued.]

Proceedings of Societies.

BATH AND BRISTOL BRANCH.

THE anniversary meeting of the BATH AND BRISTOL BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION was held at the General Hospital, on Thursday, July 15th, when there were present Drs. Davies, Gidley, Goodridge, Tunstall, and J. Watson, Messrs. Bartrum, Mason, Norman, Ormond, J. Soden, J. Smith Soden, Stone, of Bath; Drs. W. C. Fox and Davey, of Northwoods; Dr. F. K. Fox, of Brislington; Dr. Dyke, of Corsham; Dr. Woodforde, of Taunton; Mr. Vicary, of Warminster; Mr. Washbourne, of Corsham; Drs. Kay and Symonds, Messrs. Clark, Colthurst, Lancaster, Mayor, Sleeman, and Smerdon, of Bristol.

The notice of the meeting having been read by the Bath Secretary, Dr. SYMONDS, in resigning the Chair to Mr. Norman, thanked the members for their support of him during his period of office, and expressed his satisfaction, that in his successor, (Mr. Norman,) would be found a gentleman so acceptable to every member of the profession.

The minutes of the preceding anniversary having been read by the Bristol Secretary, the PRESIDENT read his Address as follows:—

Gentlemen,—My first duty in addressing you is to acknowledge my obligations and to return you my thanks for the honour you have conferred on me in appointing me the President of the Bath and Bristol Branch of the Provincial Medical and Surgical Association; an office which might have been placed in better hands—an office which was so ably filled last year that I must necessarily be placed in the position, “That when a well-praised actor leaves the stage, the eyes of men are idly bent on him who follows after.” That this is no exaggeration will be admitted by all who heard, last year, at Bristol, the eloquent and animated address of Dr. Symonds. But, gentlemen, I stand amongst friends, who will not require or expect more of me

than my capabilities are equal to, who will give to my defects all the indulgence which kindness can dictate. Gentlemen, I congratulate you on the return of this anniversary meeting, and on the number of members present, large considering the sacrifice you who are present must have made, and considering the larger number which have been kept away by the imperative duties of their profession.

The success which has attended the Provincial Medical and Surgical Association is a gratification to us all. That great improvement has taken place in our profession in the provinces no one can deny. Medical and surgical talent has acquired a higher degree of excellence, intelligence has become more diffused, and the character and position of the medical practitioner have become proportionately elevated. I think you will agree with me that some portion of this improvement has been effected by the meetings of the Medical and Surgical Association, and of its Branches. The social intercourse of members at these meetings, and the discussions on various subjects, have tended to improve and elevate the character of the profession, and to remedy many of its defects without the long-looked-for aid of legislation. It does, however, now appear that there is a greater prospect of arriving at a better understanding, and more union of opinion, amongst the members of the profession on the subject of legislation. In furthering that object the Provincial Medical and Surgical Association has rendered most essential aid, by obtaining through its various branches the opinions of nearly all the provincial practitioners, and a greater degree of unanimity, the want of which has been one great obstacle to the production of any satisfactory enactment. The new Charters obtained by our two Royal Colleges have removed some formidable impediments to practical legislation; and it is a subject of congratulation to the profession that these collegiate bodies have become convinced that, noble and excellent as their institutions were, they were capable of improvement, and of being modelled into forms more in accordance with the spirit of the age, and with the wants of the profession. Improvement in our profession has of late years been much advanced by the operation of the periodicals, and the establishment of a well-conducted weekly medical press. The journal of our Association has also contributed much towards the same object, and has proved a source of information and of gratification to the members. These publications, together with the two able half-yearly “Retrospects,” have so fully displayed the progress which medical science has made during the last year, that it would be superfluous to attempt, and impossible to accomplish, in an address of this kind, any regular enumeration.

The investigation of the minute anatomy of the various organs by means of the microscope, has been continued, and various physiological and pathological facts deduced therefrom. The structure and the morbid conditions of the kidneys are now being minutely and carefully examined by Dr. Hanfield Jones; and much light has been thrown, not only on the diseases of those

organs, but also on the morbid conditions of the system arising from organic disease, and the consequent imperfect function of the kidneys. The chemical and other changes found in the secretion of the kidneys are more constantly noticed, and carefully examined, by all practitioners in investigating the various diseases of the body, as well as the peculiar diseases of the kidneys.

The microscopic investigation of malignant growth is being pursued with zeal, and although as yet the light thrown on the subject may not have led to any curative discovery, we may hope that by further elucidation some better practical knowledge may be arrived at in that hitherto intractable class of disease.

It was well observed in the Address of the last year, that the type of disease, not only of epidemics but of ordinary maladies, varied much at different periods. In the greater part of the last year, judging from the different reports, from my own observation, and from what I have heard from others, it would appear that the amount of cases in the last year has been much below the ordinary average, whilst the number of deaths have been greater than usual, in proportion to the amount of disease.

Inflammatory affections of the thoracic viscera have formed, I believe, a considerable portion of the diseases of the last winter and spring. Cases of pleuro-pneumonia and bronchial pneumonia have been severe, and not unfrequently fatal.

My own observation and the reports of others, induce me to think that the almost forgotten and nearly forbidden remedy of bleeding, has been more called for, and more advantageously employed, than for some previous years; the peculiar type of disease may, no doubt, have occasioned this, but I am one of those who think that we have somewhat too hastily discarded this remedy from our practice, and have rushed from the rash, and it may be the fatal abstractions of blood, which at one time prevailed, too far in an opposite extreme, (a very common error in human reasoning,) and that we may have somewhat to retrace our steps, and not disregard blood-letting in every case, but allow our judgment, in the particular case under consideration to guide us. I am too old in the profession to allow my opinion to be formed on any one result, but a case which lately came under my observation may serve to explain, though not to confirm, the propriety of bleeding:—

Case.—I went some distance to see a young man, who, two weeks before had become the subject of bronchitis. His medical attendant had employed ordinary means, but after a few days his breathing became so bad, that he bled him somewhat largely, with considerable relief, but in two days more he again became worse; his medical attendant was deterred from repeating the bleeding, by the great prostration of strength in this hitherto robust man, and by the weakness of the pulse; he therefore trusted to calomel, tartar emetic, blisters, &c. When I saw him he had double pneumonia; the whole left side of the chest was perfectly dull; no respiratory murmur; the beats of the heart not audible; the pulse at the wrist very indistinct. The same state

of lung existed on the right side, excepting at the upper and anterior portion. His distress was great; he could not remain in bed, or recline in the least degree. His legs were cedematous. It was evident this state of things could not go on long, and his medical attendant agreed with me in thinking, that under the circumstances it would be justifiable to try another bleeding, which afforded very considerable relief almost directly; the quantity of calomel was increased, and the chest further blistered. The following day his medical attendant found him better, but the next day considerably worse, and guided by the relief afforded by the former bleedings, he bled him again largely; from that time his recovery was progressive, the calomel was continued for a time, but it never affected his mouth, and he has now perfectly recovered.

In cases of congestion of the brain, threatening immediate apoplexy, I cannot think it prudent to trust to the slower process of local depletion, instead of taking blood from the arm; nor in the first stage of enteritis can I think it wise, in every case, to avoid general bleeding, and apply leeches to the abdomen, which take blood from vessels totally unconnected with those which supply the villous coat of the intestine; or to rely wholly on calomel and opium, where the opportunity exists of early depletion, in addition to these means.

The asthenic influence of chloroform, which has proved so valuable in procuring an absence of pain in surgical operations, has been employed lately for the mitigation or cure of some of the more violent forms of spasmodic disease. The ease with which the effect of chloroform is produced in children, and the quickness with which they recover from its effects, might induce its trial in the violent convulsions of children. In tetanus, in hydrophobia, epilepsy, and the violent paroxysms of mania, it would be quite justifiable of employ this agent; I have had no experience of its use in these cases, but I have known it used with marked advantage in allaying the distressing paroxysms of angina pectoris.

Gentlemen, at the last annual meeting of the General Association, and at the meetings of most of the branches, the subjects, I might almost say the disreputable subjects of hydropathy and homœopathy, have been strongly alluded to, and somewhat violently discussed; it may, therefore, be expected that I should allude to them, though I confess I would rather leave to the purifying effects of time the subsidence of such impurities, than, by stirring up, render turbid the pure stream of medical science. I hardly think that good policy or good taste were evinced in some portion of the notice taken of those fallacies. Our profession is not, nor can it ever become, one of bigotry or intolerance; our duty is, to view with calmness all moral theories, to extract the good, refute the error, and live in charity with all mankind. The use of water in medical and surgical practice has been employed long before the practice was distorted into the so-called science of hydropathy. Somewhere about 1807 or 1808, Dr. James Currie published "Medical

Reports on Water, as a Remedy in Fever and Febrile Diseases, whether applied to the Surfaces of the Body, or used Internally;" and I have his fifth edition, in two volumes, published in 1814. Dr. Currie has there pointed out the principles on which his agent should be used; its advantages in local inflammation and in febrile disease. He has also shown the danger of its indiscriminate use, and the cautions necessary in employing it. Well would it have been if they who have of late years introduced this remedy as a cure for *all* disorders, had studied the principles and observed the cautions of this author. Let hydropathy be stripped of all its meretricious aid, and water will take the place it before had as a medical agent.

The only claim which homœopathy has to utility is a very indirect one, namely,—that it has induced some portion of the higher classes, who have debilitated their constitutions by luxury, and others who are labouring under a nervous and a morbid anxiety respecting their own health, to refrain from taking a deleterious amount of medicine, most frequently self-ordered, and brought them to believe, by the high-sounding names of the drugs said to be contained in their pillules, that they are doing a great deal when, in fact, they are doing nothing; the course they had before been advised to follow by every honest medical practitioner. But against this doubtful, and at all events, dishonest advantage is to be placed the allowing acute disease to take its course uncontrolled in those who have unhappily put faith in this practice; and it is not to be doubted that many lives have fallen a sacrifice to this infatuation, indeed I believe in this town a young physician, a practitioner of homœopathy, died of acute inflammation of the brain, which might have been arrested, perhaps, in its earlier state, by intelligent treatment, but I suppose, like other jealous bigots, he preferred to die in the faith he had adopted.

Another false meteor which has visited the world at various times now flourishes somewhat under the name of the dreamer—Mesmer. Now, this so-called science has no pretension whatever to the name, as even its advocates say that the knowledge and the influence of it can only be felt and possessed by a few. This admission excludes all notion of its being a science. A scientific discovery has no sooner been made than it becomes known to every one; every one can appreciate and employ it. When steam was discovered to be the efficient and easily employed agent in producing that tremendous power—a vacuum, every one could understand its principle; and when mechanical ingenuity had discovered the way to convert the motion of the cylinder into a rotatory motion, steam was made available to all the purposes we now find it. As soon as it was discovered that metallic plates, under certain circumstances, would produce the electric fluid, the fact became generally known, and its application not confined to the few; on the contrary, at every railway station the fluid can be produced, and its agency employed to any distance to which a continuous wire can be carried, thereby enabling us really to effect, (what the mesmerists

pretend to,) the knowledge of what is doing in the most distant parts. But what most provokes one's ire is, that the doctrine of Mesmer has been introduced into the treatment of disease,—that persons who are otherwise sensible people, believe that they, (knowing nothing of the medical art,) can cure by this mysterious agent, the most formidable complaints; and not content with believing this absurdity themselves, they make the most strenuous endeavour to procure converts to their faith, of which they have so much dread on some other occasions, and unscrupulously intrude themselves into the chambers of our patients, persuading them that they can cure disorders much more quickly than we can, and even diseases which we make no pretension to do more than palliate, inducing the poor creatures to believe, and probably believing themselves, that they can give an earthly immortality to our frail and perishable bodies.

One other topic only remains, and that is one of melancholy import. Two of the members of this branch have departed this life since our last meeting,—Mr. Mortimer, of Clifton, and Dr. Henry Fox, of Bristol, and of Northwoods. Mr. Mortimer was a Member of the Royal College of Surgeons in 1804. He was a successful general practitioner for many years at Cheltenham, and afterwards at Bristol, where he died in November last. He was known and esteemed by all his medical brethren, and particularly by the members of this branch. Dr. Henry Fox was the second, but eldest surviving son of Dr. Edward Long Fox, of Brislington House. He was born at Bristol in January, 1788, and commenced his medical education at Glasgow in 1804, from whence in the following year he removed to St. John's College, Cambridge, where he took his degree of B.M. in 1811, having previously studied for two years at the University of Edinburgh, where he filled the office of President to the Royal Medical Society. He then established himself in Bristol, and speedily acquired an extensive practice. He was first elected Physician to St. Peter's Hospital in Bristol, and afterwards, in 1816, was elected Physician to the Bristol Infirmary. In the year 1832 he relinquished, for the most part, his general practice, and built an asylum for the insane at Northwoods, in the county of Gloucester. Dr. Henry Fox was well known to us all; we have enjoyed his society, his hospitality, and many of us his friendship. He was an intelligent physician, and a most amiable and conscientious man, possessing, perhaps, too sensitive a disposition to contend with all the asperities and difficulties of professional life; and there is some reason to believe that the disease under which he laboured brought his existence to a more rapid close, owing to the severity with which he was visited by those who had a legal superintendence of that branch of the profession which he pursued.

I have detained you, gentlemen, somewhat too long with this erratic address, I will now thank you for your patience and indulgence, and proceed to the business of the day.

The following report was then presented to the meeting by the Council:—

Report of the Local Council for the Year 1852.

"In accordance with the usual custom it is to-day the pleasing duty of your Council to review the proceedings of this Branch-Association during the past twelve months, though from their recurrence, and the similarity of the subjects engaging the attention, the members cannot expect to receive anything more than a passing review of some of the objects that have specially interested the medical profession, or have come under our own immediate notice.

"For the last several years Medical Reform has been an annual topic not always of a pleasing nature, and apparently doomed to be a source of continual disappointment. It is well known to you that at the beginning of the last Parliamentary Session, a Bill was carefully drawn up under the direction of the Central Council of this Association, relating to this oft-attempted subject, which Bill, while embracing all the points for years urged upon the profession and the Government by the Association, was framed, with the hope of meeting the wishes not only of the majority of the profession, but also the objections of the leading examining bodies of the kingdom. This Bill, for which the profession is indebted to Mr. Hastings, the son of our valued President of the Council, received a more unanimous support from the various conflicting interests than any that had hitherto been proposed, indeed it bid fair to become the basis of future legislation, when it was abruptly stopped by the resignation of the late Home Secretary, who had made himself fully acquainted with the details of this complicated subject.

"The Central Council having requested the opinion of all the Branches on this Bill, your Local Council having drawn your special attention to it by a circular to each member, gave it the most careful consideration, and with some slight modifications, which have been published in the *Provincial Medical and Surgical Journal* of March 3rd, were prepared to give it their best support.

"Since our last meeting a Supplementary Charter has been granted to the College of Surgeons of England, making several important modifications in the election of Fellows and the selection of its Council, which will be found productive of much service, as tending to allay the former feelings of irritation, and extend the popularity of the College. The formation of a Board of Examiners in Midwifery has been one of the most important practical results of this modified Charter, whereby a great anomaly has been remedied.

"Coincident with the alteration of the Charter of the College of Surgeons is the proposal to alter that of the London College of Physicians, into which are to be introduced elements of a much more popular character than have hitherto existed in that body.

"These varied circumstances, as well as the suspension of the former endeavours to found a new licensing body for the General Practitioner, lead your Council to hope that the long-agitated subject of Medical Reform will ere long be set at rest, as never before have the various parties interested so little disagreed.

"On reviewing the proceedings of our own Branch, your Council are happy to find that the interest taken in the proceedings of the quarterly meetings continues

unabated. Those who had the gratification of hearing, at our last anniversary, the address of your retiring President, (Dr. Symonds,) can but congratulate themselves that meetings such as these have been the means of eliciting such philosophic views, confirmed as they are by practical experience, and tempered by the highest professional rectitude. The subjects brought before you during the past year have been of the usual varied character.

"Dr. Burne, at the September meeting, narrated a 'Case of Mumps,' illustrating the *sequelæ* of that complaint.

"Dr. Woodforde detailed the 'History and Appearance of a very rare Disease of the Tongue.'

"Dr. Budd gave the 'History of a Case of Abscess of the Cerebellum, originating in Caries of the Petrous Bone.'

"Dr. Swayne, in December, gave some valuable illustrations of the various cranial presentations.

"Mr. Conway Edwards detailed the effects of chloroform in different diseases.

"Mr. Barrett and Mr. Soden, at the same meeting, narrated some cases illustrating the obscurity of the inflammatory diseases of the bowels.

"Mr. Clark also exhibited a man on whom he had performed 'Dupuytren's Operation for Artificial Anus.'

"At the last meeting Mr. Bailey gave the 'History of a Case of Internal Strangulation,' presenting several points of considerable interest, and

"Mr. Nield favoured the Association with his experience in the application of nitrate of silver to the larynx.

"At this meeting Mr. Wilson introduced the subject of the payment, by the Life-Insurance Offices, of the medical attendant of those proposing to insure, but it not being customary to discuss such topics at our quarterly meetings, it was deferred till to-day, it being a subject in which the profession has taken an increasing interest; for while there is some difference of opinion as to the proper course of conduct in ordinary cases, many members are inclined to act firmly in every case, your Council will, therefore, leave it for your full discussion to-day, every member having received a copy of Mr. Wilson's motion, that if you think fit a specific resolution may be forwarded by this Branch for the consideration of the Association at Oxford next week.

"Had our meetings been marked only by the narration of the cases mentioned above, our time would have been well spent, but those who have been present at them know how much was elicited by these narratives,—how much more strongly the facts were thus impressed upon the mind,—and how, even the most experienced, must have been pleased to have his own views confirmed or modified by those around him, while to the younger members, these and similar meetings are invaluable as stimulating professional zeal, and tending to correct crude or ill-defined ideas.

"During the past year the local contributions to the Medical Benevolent Fund have been satisfactory, several of the members having increased their annual subscriptions. It is, however, always a source of regret, that every member of this Branch, having the means to do so, does not feel the duty of thus helping those whom unforeseen circumstances may have reduced to a

state of poverty and destitution. This year has been marked by its first anniversary dinner, at which, through the exertions of its many friends, £500 was collected; this sum, it should be understood, will be added to its capital fund, and the income derived from it be devoted to the granting annuities to decayed members of the profession, or their representatives.

"Coincident with, but not consequent on, the increased means of usefulness of the Benevolent Fund, your Council are grieved to state, that the Provident Fund, known as the British Medical Fund, from the slender support given it by the bulk of the profession, will probably be dissolved. Having existed upon false principles for several years, at length it was taken up by some ardent friends, and the utmost exertions used to procure the most extensive support, based as it then was upon the soundest principles, and guaranteed by the calculations and assistance of one of our most valued actuaries; notwithstanding these apparently favourable circumstances, the support has been so limited as to oblige the Committee to wind it up in accordance with the Friendly Societies' Act, under which it was registered. If this be a source of sorrow, the past year has been marked by the most vigorous exertions to found a Medical Benevolent College, embracing objects of a varied character. £10,000 having been already possessed, it will probably be carried into effect, as it has been nobly aided not only by some of the members of the profession, but also by the liberal assistance of many of the laity. The cause being so good an one, your Council, while hoping that the expectations of its friends may be realised, cannot forget that our own Benevolent Fund is the one which presents the greatest claims on our support.

"In accordance with the resolution of our last anniversary, the list of the members of this Branch was forwarded to every member for the purpose of nominating your Local Council for the ensuing year. The gentlemen thus elected are,—Drs. Hodges and Davies, Messrs. Adye and Church, for the Bath district; and for the Bristol district, Drs. Budd and Swayne, Messrs. Coates and Prichard.

"In conclusion, your Council would urge upon all the members of the Branch to use their utmost endeavours to make our meetings more interesting, by the collection of appropriate materials of instruction, and our Association more influential, by the introduction of earnest zealous new members."

It was moved by Dr. TUNSTALL, seconded by Mr. WASHBOURNE, and resolved,—“That the report of the Council, now read, be adopted, and published in the *Provincial Medical and Surgical Journal*.”

It was moved by Mr. SODEN, seconded by Mr. COLTHURST, and passed with acclamation,—“That the best thanks of this meeting be given to Dr. Symonds, the retiring President, for his zealous and efficient exertions for the prosperity of this Branch-Association during the past year.”

Dr. SYMONDS, in acknowledging the compliment, said he had to thank the Association for thus appreciating his services, and for their forbearance at his short comings; expressing his willingness at all times to devote his attention for the promotion of the Society's success and prosperity.

It was then proposed by Mr. MASON, seconded by

Dr. GIDLEY, and carried unanimously,—“That the thanks of this Branch are hereby given to the Council, for their attention to the interests of the Association during the past year, especially to those gentlemen who now leave it by rotation, Messrs. Adye, Bally, Church, Dr. Davies, Dr. Hodges, Dr. W. Budd, and Mr. Allen.”

Mr. SLEEMAN, in proposing—“That Henry Clarke, Esq., be appointed President-Elect for the ensuing year,” took occasion to congratulate the Branch, that a gentleman so well known, and so active in the pursuit of his profession, had consented to preside over the meeting.

Dr. WOODFORDE, in seconding the proposal, further eulogised Mr. Clarke's attainments.

It was then moved by Mr. VICARY, seconded by Dr. DYKE, and passed unanimously,—“That Messrs Colthurst and Bartrum be requested to continue to act as Hon. Secretaries to this Branch during the next year, with thanks to them for their past services.”

Mr. BARTRUM, in acknowledging the gratifying manner in which the resolution had been received, said that it gave the Secretaries much pleasure to be useful in every way to their professional brethren, especially to forward the interests of the Association and the quarterly meetings of this Branch. The duties, from various causes, had, during the past year, been more than usually onerous; yet, as they had endeavoured to make the work a labour of love, they were pleased that the members were satisfied with their endeavours.

INSURANCE COMPANY'S FEES FOR PROFESSIONAL REPORTS ON LIFE-INSURANCE.

The following notice has been given by Mr. Wilson on this subject:—“That the members of this branch of the Provincial Medical and Surgical Association, feeling most strongly the gross injustice of being expected to furnish gratuitously a private report of the healthful condition or otherwise of their patients to any Life-Insurance Company that may choose to apply for it, and being fully convinced that the information so supplied is for the security and advantage of the insurer rather than the individual insuring, do hereby express their determination not to reply to any questions submitted to them by an Insurance Office that does not transmit with the question a suitable fee.”

Mr. Wilson having been prevented from attending through illness, Dr. SYMONDS said, he had undertaken on his behalf to introduce the subject of the proposition; but he felt he was unable to do it that justice which the proposer would have done, as he was not so happy in methodising his thoughts. He had no objection, however, to offer a few observations to the meeting for the purpose of suggesting whether the resolution should be adopted in its unqualified form, or with some less stringent modification. There could not be two opinions as to whether the information furnished to Insurance Companies by the profession ought not to be remunerated. The information was not given so much for the benefit of the parties insured, as for that of the Companies insuring; still it was a matter for consideration whether medical men were bound to furnish

answers to their inquiries unless accompanied with a fee. It was evidently for the advantage of the Company who sought the information, for even should the report induce them to decline granting the policy, it was tantamount to a confession that they were under obligation to the medical man for saving them the risk by his information. As to the argument that the professional man was rendering a service to his patient by his information, in some instances it was quite the reverse, as an unfavourable report, by causing his rejection by the Insurance Office, absolutely did the patient an injury and damaged him for the object sought to be attained. And supposing it should be otherwise, and he succeeded in getting the policy, he had no claim on his medical attendant for information unremunerated. The question was not so much which party was benefitted as whether the information was worth paying for, and on this ground the subject was entitled to consideration. It was one in which he was less personally interested than the general practitioner, and therefore he felt less difficulty in taking the place of Mr. Wilson in bringing the matter forward. As for himself, the way in which he generally proceeded when he received an application from an Insurance Office, unaccompanied with a fee, and sometimes requiring answers exceedingly important and critical, was to fold up the paper unanswered, and say he should be happy to furnish the information whenever his fee was remitted. As a matter of form, he would propose the resolution for the sake of discussion, and hearing the opinion of the meeting, but would rather they did not pledge themselves to it without modification. He concluded by suggesting the following modification of the last clause of the above resolution.—“do hereby express their opinion that medical practitioners are justified in declining to reply to any,” &c.

Dr. TUNSTALL rose for the purpose of seconding the resolution, on the assumption that it should be adopted in its integral form, and strongly animadverted on the practice of calling on the medical profession to certify without fees in Life-Insurances. It sometimes happened that the party about to insure might be no patient at all of the professional man to whom he applied; and supposing he were, was it the practice to treat other professions in that way? If the lawyer were applied to for professional information, he would decline it on the gratuitous system, and very reasonably; and why should the medical man's time be taxed without remuneration? He really did not think the profession were bound to indulge the wishes of an Insurance Company, and contribute to their profit against their own advantage; for, after all, it was a mercantile question, and the companies were commercial bodies speculating on profitable returns upon capital. The fact was, the profession had been too ready to oblige them, and now the system had come to such a pitch, that not only questions of great importance were required to be answered, but the interrogations applied to points of the minutest detail—such as the state of the pulse—the number of respirations per minute, &c. (Laughter.) Perhaps a man whom his medical adviser had only seen two or three

times came with his paper to be filled out, as if he was entitled to the answers as an official matter of course, and scarcely to be deemed a favour. Dr. Tunstall concluded by urging the resolution in its unqualified mode of expression.

Mr. SODEN was of opinion that the resolution was unnecessary, because the practice complained of had, within the last four or five years, been much done away with by a liberal course adopted by the Insurance Companies, the most respectable of which paid the medical referees of the patient. He could not agree in opinion that the information supplied was so much for the profit of the companies as for the interest of the individuals insuring. No doubt the trading motive entered into their schemes, but as in all cases where there were two parties concerned in a contract, the benefits were reciprocal; just as when a house or other property was bought and sold, the preliminaries in establishing the validity of a title entailed costs on each side, as it brought advantages to both parties. So, a similar principle entered into the negotiations with Insurance Companies. The respective solicitors of the parties concerned were referred to in the one case, and so in the other their medical practitioners. He contended that the present resolution was not necessary; and the real question was,—If the medical man ought to be paid for his services? If he ought to be in this instance alluded to, then he was of opinion the person applying should pay him. The speaker concluded by deprecating the passing of the resolution in its original terms, as it would be compulsory, and leave the members no alternative but strict conformity to the rule of refusing to fill up the forms without a fee in every instance.

Dr. DAVIES said, he entirely concurred in what had fallen from Dr. Symonds on the subject, as to the profession being entitled to the fee; and considered his suggestion for modifying the resolution well grounded. He thought the Association would do wrong in shutting out the members from an optional course, according as circumstances, or the merits of a particular case, might guide them to insist or not upon a fee. Dr. Davies, having digressed a little into other professional topics, concluded by seconding the resolution, so modifying the rule as to give it a declaratory purport, to the effect that the members of the Association would be justified in declining to furnish information to Insurance Companies without a fee; but not to bind them exclusively to this course.

Some discussion ensued as to whether the resolution, in the form supported by Dr. Tunstall, was to be considered an original one, or in the shape of an amendment. It was ultimately decided that Dr. Symonds's qualifying motion, seconded by Dr. Davies, should be the original, and Dr. Tunstall's an amendment.

Dr. GIDLEY expressed his concurrence with Dr. Davies, and was of opinion that the fee should be paid by the Companies, because in requiring the information, they brought the medical man and his patient often into an invidious relation one with the other; for if he was obliged from a sense of truth and honour, to give an

unfavourable report, it caused ill feeling between them, and ultimately injury and loss to the practitioner. If, however, the report should be favourable, the advantage was mutual, and both parties benefitted.

Mr. CLARK having offered some additional remarks on the subject,

Mr. STONE expressed himself strongly opposed to the system complained of, and to which the notice applied. Though some offices had consented to fees, many still withheld them; and if some strict rule were not adopted, the junior members of the Association would suffer grievous wrong; for if, on application, they gave their refusal to report without the fee, those of long practice would be referred to as examples condemnatory of such a refusal; and they would be asked why they were so scrupulous, while Dr. so and so, and Mr. so and so were so ready to comply? He should, if called on, give his support to the original proposition, unmodified.

After a few observations from Dr. WOODFORDE, Mr. SODEN, and Dr. KAY, Dr. TUNSTALL moved the resolution on paper as an amendment to Dr. Symonds's motion, which was seconded by Mr. STONE.

Mr. JOHN SODEN would feel himself justified in doing, individually, what the unmodified rule suggested; but submitted that it would be impracticable to enforce it as generally binding, and he quite accorded with Dr. Symonds's suggestion. The medical men had been used as instruments by Insurance Companies, to their own disadvantage, having been often called into courts for the purpose of aiding them in legal disputes. But with regard to protecting themselves by combinations, he greatly disapproved of it, it was so much like the strikes of amalgamated societies in trade,—a course both illegal and undignified.

The PRESIDENT then put Dr. Tunstall's amendment to the vote, which was lost; and the original motion was next put, and carried almost unanimously.

It was then unanimously agreed that a copy of the resolution should be transmitted to the Anniversary at Oxford, for the consideration of the Association.

After a most interesting paper had been read by Mr. Clark the meeting broke up.

About twenty gentlemen dined together at the Castle Hotel.

MEDICAL BENEVOLENT FUND.

SEVENTEENTH ANNUAL REPORT OF THE MEDICAL BENEVOLENT FUND FOR THE YEAR 1851-52.

Read at the Twentieth Anniversary Meeting, held at Oxford, July 22, 1852.

"The year just closed may truly be said to have been a remarkable one in the history of your Institution; it has been remarkable for its successes and reverses;—remarkable for its income and expenditure;—remarkable for its loss of friends by death, and for the increase of its patronage;—remarkable for the steady augmentation of its income, as well as for the larger number of claimants upon its bounty;—and remarkable, above all,

for the improved tone of its correspondence throughout its whole length.

"To justify these assertions, it may be stated more particularly, that it has pleased God to deprive them of the steady uniform support of their late-lamented President, whose part has been chiefly shown in the origin of your institution,—who for many years presided with fostering care over its every movement, and who was always found its most zealous friend. In the last days of his existence his anxiety for the welfare of the Benevolent Fund was most marked. But he is gone to the abode of the just and good, and your Committee have recorded the deep sense of their obligation to him in a feeling tribute of their esteem, addressed to his nearest surviving relative—one who inherits his interest in the good work before you; and who, besides continuing her brother's subscription, has, in the kindest manner, unsolicited, given a donation of £20 to your funds. The loss thus sustained by your Committee they have applied themselves to repair, and they have much pleasure in announcing that Sir James Clark, Bart., has kindly consented to become your President.

"Circumstances subsequently led to the resignation of Dr. William Conolly, who had held the office of London Secretary to the Committee, and they rejoice that they have been enabled to supply the vacancy thus occasioned through the acceptance of that office by their valuable *confrère* Mr. Toynbee, whose active and efficient services have already proved him to be a most valuable coadjutor.

"The amount of subscriptions during the past year has been no less than £655. 8s. 7d., a sum exceeding that of the former year by considerably more than £100. But, on the opposite side, it is to be stated, that the amount given in benevolent aid has been £676. 14s., an amount exceeding that of the preceding annual period by upwards of £200, thus showing, that if your income has been larger, so likewise has your expenditure been augmented, in more than a proportionate ratio, and leaving you with a debt due to your Treasurer of £4. 4s. 9d., instead of with a balance in his hands of upwards of £50. Your Committee call upon you therefore most earnestly to strengthen their hands, by increasing your direct income applicable to the relief of the daily occurring claims upon their sympathy.

For a proof of the useful application of this income your Committee refer you to the following statement of the parties who have been relieved during the last year, viz. :—

Physicians	4
Surgeons	25
Apothecary	1
Wives of Physicians	1
Wives of Surgeons	3
Widows of Physicians	8
Widows of Surgeons	25
Daughters of Physicians	3
Daughters of Surgeons	7
Families of the above, containing individuals, numbering					164
Total	241

"Thus is it, that in the exercise of their merciful office, your Committee during the last year have rescued 240 individuals from a state of great wretchedness, and placed them in a state of comparative comfort: a detail of some of these cases will be annexed to the Report

your Committee regret to add, that to some calls they have been compelled to refuse aid on the ground of intemperance.

"Your Committee would remind you, that by their constitution the whole of their funds accruing from donations are impounded, and added to their accumulating fund for the purpose of granting annuities in those cases to which they are appropriate. Your Committee are pleased to inform you that £86. 5s. have been thus expended this year; and they beg again to impress upon you the importance of this branch of your institution; and the fact that the small annuities thus granted to those who can enjoy them *at home*, and can be at the same time surrounded by all the charities of life, are infinitely to be preferred to those which may be obtained in any other less private way, and without these advantages.

"Your Committee refer to a statement in their last Report, that it was their intention this year to hold an anniversary festival. This intention they have accomplished with complete success. A public dinner was held on the 20th of May, at the London Tavern, under the kind presidency of the Earl of Carlisle whose eminent services in this sacred cause will be long remembered by all those who were present, and by all those who take an interest in the prosperity of your fund. The amount of donations received during the year, including the amount of dinner tickets received at this festival, has arisen to no less a sum than £967. 8s. 5d. The expenses attendant upon the public dinner amount to £224. 7s. 6d., leaving a balance, after payment of the annuities and the balance due to Treasurer last year, and the special donations, of £712. 2s. 11d. Of this sum there has been invested £678. 19s. 6d. in the purchase of £300 Bank Stock, leaving a balance in the hands of your Treasurer of £33. 3s. 5d. Your Committee are thankful to have it in their power to report to you that they have been able to grant two fresh annuities (one having dropped) during the year; and by this increase of their permanent income, they hope at the next half-yearly period to extend their aid in this way. It will thus be seen that the gross annual amount received this year has been, in subscriptions, £668. 11s. 9d., and in donations £967. 8s. 5d., together with £90 interest of Bank Stock, making together a total of £1,726. 0s. 2d. Though their progress may have been slow, yet it has been sure; and your Committee reflect with pride and pleasure, that by never exceeding their permanent income, they are able to rely upon the continuance of their annuities with unerring certainty.

"Your Committee desire to express their regret towards the conductors of a somewhat analogous institution, which has become extinct during the last year, "*The British Medical Fund*." Though the principle design of this fund was *provident* in its nature and essence, yet, under certain circumstances, its operations became *benevolent*; and your Committee would remind you that the loss of this fund renders it more imperative upon all their friends and supporters to strengthen the things which remain, that in the hour of distress and destitution the wretched and the indigent may find a sure place of refuge. Your Committee would earnestly recommend to all the subscribers of the *British Medical Fund* a transference of their subscriptions from that

extinct fund to your own *now more than ever needed institution*.

"Your Committee would invite your attention to the possibility of grafting a Sickness Relief Fund upon your own Fund. The Committee are aware of the many difficulties attendant upon such a fund, and especially the essential departure from your principle of being a purely charitable fund, and yet they would be glad, if it were possible, to enlarge the sphere of your usefulness.

"The fact of the increasing importance of your own fund is shown by the record, that 65 cases have been relieved this year against 50 in the last year, and 45 in any preceding year.

"Has, then, misery and wretchedness increased in the last year? Or has it only been developed and become more apparent? Your Committee incline to the latter explanation; but in either case they rejoice in the relief of the more frequent misery, or in that which has become more apparent through the more extended knowledge of your Institution, and of the benefits which it confers.

"Your Committee cannot quit this part of their Report, and the fact of the large increase of their patronage and support arising from their public dinner, without again thus publicly recording their deep sense of obligation to Dr. Burrows, whose unwearied energy and untiring activity in your cause were followed by such happy,—such grand results; and they would here record their belief, that the success of your Institution is, *ceteris paribus*, dependent upon the energy and zeal with which its merits are recommended by its advocates.

"Your Committee refer with much satisfaction to a donation of £5. towards your fund, from the Lancashire and Cheshire Branch of the Provincial Medical and Surgical Association; and they do so for two reasons: first, that this Branch has paid its own expenses without aid from the parent fund; and next, that it has been enabled to make this donation towards your benevolent fund from the excess of the income thus contributed for their expenses, an example in both instances well worthy of imitation.

"Your Committee refer to the comparative statement attached to their report, in order to show the steady increase of their means, and the augmented sphere for the distribution of the funds with which they have been entrusted. But they cannot quit this part of their report without placing upon record their high sense of the exertions of your Treasurer, to whom they are mainly indebted for their success, and who reports to them the very large and marked growing interest exhibited in his correspondence of the last year over any former similar period of time; thus proving that your Institution is deepening its hold upon the hearts of your subscribers, and becoming more stable by the enlargement of its *principled basis*, viz.,—the simple, pure, uniform design of doing good, and all the good they can, amongst the children of misfortune in the large professional family.

"Your Committee are deeply thankful to many individuals who have assisted them in various ways during the last year, and especially to the renewed kind exertions of their lady friends in various parts of the kingdom; also to the several branches of the *medical press*; to Dr. and Mrs. Wake for their kind reduction

of their list of subscribers into alphabetical order; to Mr. Leete, of Thrapstone, for his benevolent conception, and for his diligence in carrying out that conception, viz.,—of benefiting the Society by a small contribution from every Poor-Law Medical Officer. That the plan was not more productive was no fault of Mr. Leete's. Success is no criterion of merit. He has done what he could, and "angels could no more;" and the approbation of his own heart will be *with him, —the most certain, effectual, and ample reward.*

"Your Committee would be wanting in respect to themselves, and in their duty to you, did they not especially call your attention to the fact that they begin this year with a small debt, instead of a balance in hand; and did they not urge upon their friends, by every consideration of prudence and charity, to extricate them at once from this position, and to place them upon such a pinnacle of security as shall enable them to continue their aid to the wretched and the helpless.

"Your Committee cannot take their leave of you for another year without expressing their grateful acknowledgments to their banker, Sir Walter Farquhar; to Mr. Churchill for many kindnesses, and for the use of his rooms for the purposes of this Committee; and generally to all those who, in sentiment and in action, have shown themselves devoted admirers and supporters of your fund.

"And while they claim the first place of usefulness and benevolence in the career of charity, they would express their kindly feeling and best wishes towards 'The Medical Benevolent College;' and while they wish it success, they may also hope for the perfection of its working, and the stability of its purposes.

"In conclusion, your Committee would quote their own words on another occasion, when speaking of their Institution. It 'is not a huge overwhelming charity, calculated to foster indolence and improvidence; but it is the bit of bread and the cup of cold water which cheer the fainting spirits and reanimate the aching heart.'

"'It is more blessed to give than to receive.' 'To do good and to distribute forget not; for with such sacrifices God is well pleased.'

"Signed on behalf of the Committee,

"WILLIAM NEWNHAM, Chairman."

Correspondence.

ON THE "JOURNAL" DISCUSSION.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—As the decision made at Oxford concerning the future management of the *Journal* was informal; and as the question at issue is so important in its nature as to render it desirable that *every* member should have an opportunity of recording his opinion, I beg respectfully to suggest that the sense of the entire Association be taken on the subject; and if each gentleman will incur the very slight trouble of stating in writing whether he does or does not advocate a change in the

time or place of publication, and will forward his communication to me, I will with pleasure peruse the same, and make an accurate report of the result through the medium of your pages.

The expenditure of three minutes, and a penny, by each Associate, would thus furnish satisfactory data, (and I think the *only* satisfactory data,) on which the radical alteration proposed by Dr. Cowan might fairly be sanctioned or prevented. Hoping that this plan may be generally regarded as legitimate and just,

I remain, yours faithfully,

P. HENRY WILLIAMS, M.D.

Worcester, August, 1852.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Something akin to a sense of justice prompts me to trouble you with a few lines, which you can either print or receive as a private note, as may seem best to you.

For the last eight years I have been a member of the Provincial Medical and Surgical Association, and possess eight *bound and cut* volumes of the *Journal*, and I am not ashamed to confess, (in spite of the risk of being pitied for my simplicity,) that I value them exceedingly as a fund of useful practical information, of easy access—because well indexed, and above all, worthy of esteem, because, being at warfare with no other journal; their pages are unstained by ill-nature or sarcasm, and contain valuable matter wherever found, regardless of its source.

I am very far from asserting that the *Journal* is incapable of improvement, or even from saying that steps should not be taken to better it, but there is no reason for underrating what we have got; and as regards the Editors, I have little doubt that many are of the same opinion as myself—that they have worked at their very difficult and delicate task of pleasing everybody with ability, tact, and never-failing courtesy at least, and, let me hope, with much more success than the discussion at Oxford might lead one to imagine.

I am, Sir, (I wish I could still say Gentlemen,)

Yours very obediently,

THOMAS EDWARD AMYOT.

Diss, Norfolk, August 5, 1852.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I have waited until after the Oxford meeting to reply to your "Editorial remarks" on the subject of the *Journal* and my letter in the number for July 7th, and now I must own that the opinions expressed in that communication are strengthened, not only by the Oxford discussion, but by those which have taken place at Branch meetings, and even by your own remarks. It is necessary, however, to set you right as to some points alluded to in your above-mentioned leading article. You say, Sir, that the cost of the *Journal* to each subscriber is *ten shillings* only; this is a wrong assertion. Some gentlemen subscribe to the *Journal* and pay ninepence for every number; in fact, 19s. 4d. a-year, which is the sum I named. Again, the *Medical Times*,

the paper mentioned in my letter, (and not the *Lancet*,) is furnished stamped for 25s. per annum, and this I can prove by their bills, although you deny it. I will not go so far as one of your correspondents, as to say that the *Journal* is "a bad article at a high price," but I will say it is a "very improveable article at an improveable price." From Dr. Cowan's declaration of the estimate given by a London printer, (which I think he is not bound to make public,) I have no doubt but that the *Journal* may be published weekly in a much improved form without an increase of the subscription. There is an article of expenditure in the annexed account—"Tainton, for binding Vol. xviii. of 'Transactions.'" I beg leave to say that the copy I had sent me was not bound, but merely stitched together. I should be sorry to see the "Transactions" discontinued, but would prefer an improved weekly journal to the rather shabby way in which they are now irregularly sent.

The discussion at Oxford will I hope effect much good. Dr. Cowan can, and I doubt not will, defend himself from the severe and even unjust strictures which have appeared in the last *Journal*. I would add that it is not likely that the *Medical Times* should wish to have a London rival, and more especially when it is remembered what a large amount of vituperation, and virulent abuse appeared some time since in that paper against the Association and its *Journal*.

Dr. Ranking, after a little show of that temper which was apparent in a late correspondence, has resigned the Editorship. I, for one, trust that all ill-feeling between the hostile parties has "gone" with his "occupation," and that the present Editor, under whose management our *Journal* has much improved, will still continue his endeavours to raise the publications of the Association, so that the members may not be obliged to take the *Medical Times* or the *Lancet* to make themselves acquainted with what is going on in the medical world, as they are now obliged to do.

I am, Sir, your obedient Servant,

W.

[We have nothing to do with the "Transactions," which are Edited by the Secretary.—ED. J.]

ON MR. TOYNBEE'S NEW AURAL APPARATUS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—As a member of the Association, I regret that the pressure of my professional avocations prevented me the pleasure of attending the meeting at Oxford. If I had been present, I should have considered it my duty to show the impossibility of patients using any such apparatus as that proposed by Mr. Toynbee, in cases of perforation of the membrana tympani; in the first place from the irritation it would invariably produce; and secondly, from its inefficiency, inasmuch as it tends to do the very opposite of that which is essential to success in these cases, namely—to preserve the opening into the tympanum, and not close it. Success never follows the use of my remedy—the moistened cotton,

unless it be so adjusted as to leave an opening into the tympanum. There can be no doubt that the cotton operates by affording support to the remaining portion of membrana tympani, or of the ossicula of which they have been bereft by the lesion of the said membrane.

I can tell Mr. Toynbee, from experience in many hundreds of cases, that to make the tympanum a shut chamber, would deprive the patient of whatever degree of hearing he may otherwise enjoy. I can tell him, also, as the result of an infinity of experiments, that he will never find a better appliance than cotton moistened in water, or the saliva of the patient. Simple as the remedy is, the irritation it produces is sometimes so great as to preclude its employment, or, at all events, necessitate its suspension.

Every annual gathering of the Provincial Association brings forth some pretended novelty in aural surgery, which either from inefficiency or absurdity dies in the birth. I am a specialist myself, still I would say a jealous eye should be kept upon specialists' communications at these meetings, and their value tested before being allowed to be read; for whether good or bad, publicity is given through the newspaper reports, and thus the object of the writer is gained, sometimes at the expense of the interests of science and humanity.

I have the honour to be, Sir,

Your obedient Servant,

JAMES YEARSLEY.

15, Savile Row, July 30, 1852.

NEW VACCINE VIRUS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I have a few glasses charged with good vaccine virus, very recently taken, which I shall be happy to forward to any of your readers requiring it, who will send me a pre-paid envelope.

I am, Sir, yours truly,

T. P. FERNIE.

Kimbolton, August 9, 1852.

Foreign Department.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

Report on Syphilisation.

For the last fortnight the Academy has been almost exclusively occupied in discussing a report on the extraordinary plan lately proposed by M. Auzias-Turenne, for the curative as well as the prophylactic treatment of syphilis by inoculation. At the latter end of 1851 a Committee was appointed, consisting of Messrs. Velpeau, Ricord, Lagneau, Roux, and Bégin, to examine into and report on the case of a young physician who had been treated on this plan; and on the 20th July last the last-named physician read the

report to which we have alluded above, which embraces a consideration of the two questions at present agitating the Parisian medical world; viz.,—1st, the transmissibility of syphilis by inoculation from secondary sores; and, 2ndly, the value of inoculation in the prophylactic and curative treatment of syphilis. It appears that Monsieur L., the above patient, was not under the care of the alleged discoverer of syphilisation, as the process is named, but was self-treated. M. Auzias-Turenne having, as he alleged, seen him, declined to undertake the experiment, after, however, himself making one inoculation. Nevertheless, as far as the case goes it does not appear to have stayed the progress of the disease towards its ordinary termination in secondary symptoms, since, in spite of innumerable inoculations, a papular eruption and ulceration of the tonsils made their appearance at the end of nine or ten weeks from the commencement. The theory of M. Auzias-Turenne is founded upon the law first propounded by Ricord, but which has not yet received full assent in this country, that the system is only liable to one attack of syphilis during life, in this respect assimilating syphilis to variola, measles, &c. It was, therefore, proposed, to inoculate all those who are peculiarly liable to the disease with pus obtained from a previous inoculation of a mild form of syphilis, in the hope that by so doing they would ever after be able to indulge their appetites with impunity. But M. Auzias-Turenne has also superadded the theory that the disease may be cured in the following curious manner, viz.,—by inoculating, at successive short periods, with matter obtained from chancres of three degrees of intensity; that is to say, thrice with matter from a phagedenic sore, thrice with matter from an indurated chancre, and thrice with matter from a chancre in a healing condition, or from a secondary sore of a healthy character. After carefully investigating the case of Mons. L., together with two other patients treated in the same way, the Committee report—first, that the facts relative to the transmissibility of syphilis from inoculation by the pus taken from a secondary sore, are not so clear as to warrant any conclusion; but that with regard to syphilisation, considered both as a prophylactic and as a curative agent, it is not desirable to have recourse to its practice. It does not appear to us necessary to go into the arguments against its prophylactic use, adduced by the Committee, since they will readily present themselves to every British practitioner. We are surprised, however, to find that the report has led to a long discussion, in which M. Malgaigne (whose authority alone would induce us to hesitate before condemning the whole theory as void of foundation,) and M. Depaul support the views of M. Auzias-Turenne. As the whole depends upon matters-of-fact with which in this country we are not likely to be interested, it is unnecessary to do more than record the names of the speakers *pro.* and *con.*, which we shall content ourselves with doing, merely remarking that M. Ricord appears to have given the *coup de grace* to the advocates of the new doctrine, in a long speech made in the 3rd of August before the Academy, in

which he controverts, in a masterly manner, the facts adduced by MM. Malgaigne and Depaul, after which he concluded with the following position:—That even if syphilisation be what it is pretended, it would be a misfortune to mankind, and ought to be strictly prohibited, both as a prophylactic and curative agent.

On the 10th instant the fourth day of the discussion was opened by M. Gibert, followed by M. Larrey, both of whom are strongly opposed to the theory, but nevertheless, M. Bégin, who presented the report, was allowed to occupy the time of the Academy by a long speech, so that, in spite of strong calls for a division, MM. Malgaigne and Depaul were allowed a rejoinder. The latter of these gentlemen delivered a discourse, in which he chiefly dilated upon the possibility of the transmission of syphilis to the lower animals, instancing in particular a cat, which displayed secondary symptoms after inoculation, and was delivered of four kittens, which contracted the disease *in utero*. It is expected that the Academy will come to a decision at their next sitting, which we will duly report, for, though we think that the subject does not deserve the lengthened attention given to it in France, still it should be known to all those who take an interest in the proceedings of our volatile neighbours.

New Instrument for Performing Tracheotomy.

M. Gerson, of Hamburgh, has invented an instrument, which is similar to a three-branched speculum in principle, for the purpose of opening the trachea without risk of hæmorrhage. It is delineated in the number of *L'Union Médicale* for July 24, and consists of three branches, which, when closed, form a sharp point, with a shoulder about four or five lines from the point, which will prevent its introduction into the trachea to a greater depth. In order to introduce it, a small incision through the skin is first made with a scalpel, which should afterwards be used to separate the vessels, so as barely to show, with the aid of the nail of the left index finger, the space between two cartilaginous rings. First, fixing the trachea with the left hand, the point is then introduced up to the shoulder, when, by turning the screw, the three blades are separated sufficiently to dilate the ligament so as to allow of the introduction of the canula; the instrument is then withdrawn, leaving none of the consequences occasioned by the flow of blood so frequently attendant upon tracheotomy by the usual modes.

New Instrument for Depressing the Lens in Cataract.

At La Charité, M. Gerdy has introduced a needle, which he uses, to divide the posterior surface of the capsule, and depress the lens; it opens in two portions, and is somewhat similar to one lately invented by Mr. Bowman, for the purpose of removing any portion of capsule left after extraction or depression. We confess we do not see the advantage of M. Gerdy's needle in depressing the lens; but for other purposes, such as the formation of artificial pupil, we think it may be rendered of great avail. M. Gerdy describes it as cutting like

scissors, "*leurs lames font l'office de ciseaux*;" and if so, we should like much to find our instrument-makers following the example of Charrière, the maker—since we should despair of such a feat in London as the manufacture of a pair of scissors with the form and point necessary for their introduction through the sclerotic into the posterior chamber, or even through the cornea to the iris.

Hydrophobia.

M. Clot-Bey has attempted to explain the rare existence of this malady in Egypt, where dogs are exceedingly numerous, by the theory that the disease is due to the suppression of the venereal appetite of the dog in those countries where it is prevalent, while in Egypt they are not interfered with, and hence the rarity of the attack. [This theory is supported by the fact that the female is rarely the primary subject of the disease; indeed we know no well authenticated case in which a bitch has been attacked, without being able to trace the disease to a bite from one of the other sex. It is a subject which deserves some further examination.—Ed. J.]

GERMANY.

[In reply to an application for foreign intelligence, the following extract from a letter just received by our correspondent, from a celebrated professor at Hamburg, has been forwarded to us. We insert it with pleasure, as showing the difference between the intelligence of the German public and that of our own country, in which the lecturer on Electro-Biology often commands the belief of men as well as women of the highest education, indeed, as often have been observed, the more cultivated the manners (we will not say intellect) the greater the credulity.—Ed. J.]

On the Transplantation of Electro-Biology into the soil of Germany.

Hamburg, July 28th.

Dr. Dew, an American physician, has the merit of not only bringing this new fruit of the exuberant human intellect into Germany, but also of warning against its cultivation, by the way he introduced and praised it. We call it a new production, but really it is the offspring of the old root, whose name was Mesmeria officialis, and which here is nearly rotten and forgotten. We leave the old custom of invoking the assistance of the nine sisters, and narrate, only aided by veracity, (not always Clío's companion,) the arrival and instantaneous fall of that doctrine in Germany.

Hamburg was the first port in which the American vessel took shelter, but immediately after its entrance became a wreck. The Doctor announced, that he would enlighten the public by his lectures and experiments, and a pretty large number of ladies and gentlemen, who wished to become adepts in the so-styled new art, entered the Tonhalle, in silent expectation of a full explanation of the mystery. The introductory lecture left the minds of the audience in hope, of "a charm from every woe."

Doomed soon to fade! The wizard applied his

miraculous wand—I mean his fingers—and when he believed, that the subjects of his choice were in the trance, he explained—"Now you cannot see, speak, &c.!" But his orders were only followed by the general laughter of the audience, for the subjects, instead of feeling the prodigious influence of the master, participated in the exhalted state of the whole assembly, until the astonished sorcerer left them in the self-same darkness (as to his skill and hyperphysical forces) which they had been in before. In a Hamburg newspaper he endeavoured to excuse his failure in English letters, of which the style and grammar were not worthy of a wizard. His principal objection—that the auditory was not sufficiently imbued with the knowledge of the English language, we can refute by the well known fact, that at Hamburg, in every congregation of the higher class, there is a number of persons equal to understand the contents of an English lecture. The Doctor left Hamburg, for a second trial was not conceded to him by the government, fearing a heavier outbreak of the discontent of the deceived public than the former hissings, &c.

At Berlin, the newspapers and the police were of one accord, in not allowing that the Prussian nation should be allured and deceived by the novelty of a tempting art.

Dr. Dew returned to the neighbourhood of Hamburg, and obtained permission to lecture, and awake the yet slumbering intellectual powers of the Altona public. A journal of that town showed the scientific unworthiness of the so-nicknamed art; and its warning voice had the effect of evoking an answer of the industrious Doctor, translated into English by an Italian.

A reply cautioned the Doctor not to again tease the inhabitants of that latterly badly-cheated country. But the Doctor, *perhaps* no deceiver, but deceived himself, tried the patience of a small audience, of which fifteen persons gave themselves up to the manipulations, &c., of the Doctor, with that effect, that three nobodies (one of them, the owner of wax-works) executed the will of the (still living) performer of so great deeds, as, for instance, to tantalize and intoxicate the trifolium by pure water, if their benefactor's will persuaded them that they drank wine, brandy, &c.

But the purses and the mind of the public did not show any further connivance with the electro-biological doctrine and its phenomena; and a satirical comment in a much-read paper excited the hilarity of the populace.

In his above cited answer, Dr. D. had claimed the assent to the doctrines of electro-biology of such very renowned men as Brewster, Brodie, Holland, two hundred physicians of England and Scotland, (he named Redfern, Aberdeen,) and his bills posted up at every corner house, were filled with the names of a number of English PRINCES, never heard of.

Finally, he promised that he would persuade the public of the truth of his doctrine by a treatise, destined to dissipate the fog, that is yet obnubilating the ideas of his antagonists; for he cannot but be discontented with the reception, the thick Protean air, endarkening the German intelligence and judgment, opposed to his well-meaning elucidations of supernatural forces and Richenbachian Od-dities.

"Still as the tide of ages rolls away,
Truth charms the world, unconscious of decay."

Reviews.

On the Anatomy and Physiology of the Male Urethra, and on the Pathology of Stricture of that Canal.

By HENRY HANCOCK, F.R.C.S., Senior-Surgeon to the Charing-Cross Hospital, &c. London: Highley and Son. 1852. 8vo, pp. 86.

THIS unpretending little volume comprises the *ipsissima verba* of three Lectures delivered by Mr. Hancock, in the Session 1851-52, to the Medical Society of London, as Lettsomian Professor of Surgery. The first of these consists of an examination into the intimate structure of the muscular apparatus surrounding the urethra, in which Mr. Hancock, by the aid of the microscope, not only demonstrates the presence of muscular fibres investing the whole length of the urethra, but proves their existence in two layers, one between the mucous membrane and the corpus spongiosum, the other external to that body. In this Lecture he also, in justice to himself, claims the discovery of these fibres, or rather the priority of their correct demonstration, which had been assigned to Köl liker by the writer of the article "Urethra" in the "Cyclopædia of Anatomy and Physiology," but which the writer of the article and the Editor have since most handsomely admitted to belong to Mr. Hancock.

This gentleman we believe to be the first to trace muscular fibres continuously from the two layers of the muscular coat of the bladder to the extreme orifice of the urethra, and also to show that the vesicles and ducts of the prostate gland are invested by muscular fibre, the latter deriving its covering from the muscular coat of the vas deferens. These important demonstrations, together with that before mentioned, of the double investment of the corpus spongiosum, entitle the Lettsomian Professor to take a front rank among the present race of microscopical physiologists, if his discoveries receive the confirmation of contemporary minute anatomists. But, whether correct or not, Mr. Hancock's lectures have been received with applause, and will be read with interest by all who are engaged in the treatment of that troublesome class of diseases which attacks the bladder in the male. It is quite impossible in the short space which we can devote to this subject that we can do justice to the clearness of Mr. Hancock's

descriptions, or to the beauty of the woodcuts by which they are illustrated. Our readers, we trust, will obtain the book for themselves; indeed, no surgeon ought to be without so important an addition to his library.

The second lecture is, perhaps, even more interesting than the first; abounding with original ideas, which bear the impress of truth, as well as talent. It is the physiological sequel to the dry anatomy of the first lecture, being an account of the process of normal micturition; and in it we find the following passage, which is a good specimen of the author's style, and an example of his remarkable power of thinking for himself. After observing that the abdominal muscles are often impediments to passing water, rather than aids to that process, he goes on to explain the reason, as follows:—

"I will now endeavour to explain how in retention of urine, where the bladder is distended, the abdominal muscles by their action tend to maintain that retention, and oppose the flow of urine. It is a circumstance arising from the anatomy of the part, and one which has not met with that attention from authors which I believe its importance deserves. The urethra is attached to the body and ramus of the pubis by strong and dense fascia, and by the suspensory ligaments of the penis, so that it is an error to imagine that it only becomes fixed where it passes through Camper's ligament. A careful examination shows that an equal length is attached to that which is pendulous; if a man has four inches and a half of pendulous urethra, he will have four inches and a half of attached, a point of considerable importance in the manipulation of instruments. The result of this arrangement is, that where the bladder is distended so as to be raised out of the pelvis beyond its usual limits, it forms with that portion of the urethra behind the suspensory ligament of the penis, a species of inverted cone, the apex of which is formed by the membranous portion of the urethra, as it lies beneath the sub-public ligament. Hence, when the patient strains or makes undue efforts at micturition, the posterior and middle fibres of the levatores ani muscles tend to raise the bladder, and tilt it still more forwards; whilst the anterior fibres, drawing up the prostate gland, must compress the membranous portion of the urethra against the unyielding sub-public fascia and ligament, and thus obliterate the canal for the time being. Under these circumstances, if we attempt to introduce a catheter, we should always do so with the patient lying on his back, and not in the upright position. And this, moreover, explains how it so frequently occurs, in case of stricture, that the greater the efforts, the greater will be the pain and difficulty of micturition, and the smaller the stream."

The third lecture is confined to the pathology of stricture, from which we can only make one extract, but this is so interesting that we cannot avoid laying it before our readers. After demon-

strating, at page 74, the existence of a false membrane attached to the inner surface of the urethra, Mr. Hancock goes on with the following remarks :—

“The existence of this false membrane was proved by some points of great interest. Among others, that although this newly-deposited structure appeared to be invested by mucous membrane when examined by the naked eye, the investment, though smooth and shining, did not possess the actual organization of mucous membrane, but when viewed through the microscope, presented more the character of condensed cellular tissue. It did not possess either villi or papillæ upon its free surface. It was not invested by epithelial scales; and what was extremely interesting, as incontrovertibly proving the non-identity of this membrane with the proper mucous canal, we found that, by carefully dissecting it away, we came down upon the layer of epithelial scales, separating it, as it were, from the proper mucous membrane of the urethra. We could not detect any appreciable change in the structure, either of the proper mucous membrane of the urethra or of the parts surrounding it; and hence we could not arrive at any other conclusion than that, in this instance at least, the prevailing notion that permanent organic stricture (other than the bridle constriction) was always produced by mischief without the canal, was erroneous; and other cases which we have had the opportunity of examining have not only strengthened this opinion, but have led me to conclude that it is not merely a possible but a frequent cause of this malady. There was another point also of the greatest interest, and one which, so far as I can trace, has never been noticed before. We have seen that this false membrane was for the most part adherent. It was so for about an inch of its anterior extent, where we have observed it so closely attached as almost to be identical with the subjacent tissue; but towards the bladder this new structure sent off two processes, which extended to the prostate, and became lost on the mucous investment of the outer part of the sinus prostaticus. These two processes were the limbi of a semi-lunar valve, constituting the vesical extremity of the false deposit, which was here separated from the subjacent mucous membrane to the extent of some half an inch, constituting a regular valve, having its free lunated edge towards the bladder, whilst elsewhere it was continuous with that portion attached to the urethra. On carrying a probe from the bladder along the urethra, it passed under this valve, and entered a blind pouch, of considerable size when viewed in relation to the parts; whilst the appearance of the valve was very similar to that of one of the semi-lunar valves at the commencement of the aorta or pulmonary artery.”

At page 83 is a curious experiment to prove that retention of urine may be caused by viscid mucous only in the prostatic portion of the urethra; an observation which we do not recollect to have met with before. Indeed the whole of this little volume is one mass of originality; and though we may not always be able to follow Mr. Hancock in his inductions with implicit

faith, still they are always of such a nature that we cannot disprove the position assumed.

The Symptoms and Treatment of Pregnancy. By W. J. ANDERSON, F.R.C.S. London: John Churchill, 1852. 8vo, pp. 119.

Nothing can afford a greater contrast to Mr. Hancock's volume than the one now under consideration; for we have carefully looked through its pages, and can find nothing which may not be culled by any tyro from the pages of Ramsbottom, Murphy, and Churchill, or, in fact, any modern writer on Midwifery. If, therefore, the book is intended for the professional reader, it is unnecessary to those who are already in possession of either of the above works or their congeners; and, if intended, as we should suspect, for the eye of the patient rather than for the professional attendant, we would suggest some notification in the preface to that effect; in which case the book itself would be removed from our list. However, in neither case do we think that the book can be useful, being as much above the level of the general, as it is below that of the medical, reader.

The Physical Diagnosis of Diseases of the Abdomen. By EDWARD BALLARD, M.D., Lond. London: Taylor, Walton, and Maberly. 1852. 8vo, pp. 276.

IN this age of monographs we require certainly either originality or research to induce us to prize any addition to the already extensive list of books devoted to special descriptions of disease. The present volume, is, however, one of great labour, and is a carefully-arranged generalization of the known phenomena of abdominal diseases, without any pretension to anything more. The first part consists of an excellent description of the various modes of conducting a physical examination of the abdomen, together with the results afforded by this in health and disease. The second part enumerates those diseases which give indications of their presence on a physical examination; whilst the third part, which is really valuable to the young practitioner, is a tabular enumeration of the most remarkable physical signs, with the diseases by which each may be occasioned; to these are also attached numbers referring to the preceding paragraphs of which the first two parts are composed. Thus,

under the heading, "Fluctuation felt in Pelvic Tumours," we find the following diseases enumerated, with the numbers attached, referring to the paragraph in which each is described:—

339. *Fluctuation felt in Pelvic Tumour, 46.*

Peritoneal abscess in pelvis, 175.	Retention of menses, 214.
Distension of bladder, 184, 206.	Abscess of ovary, 230.
Pelvic Abscess, 187.	Encysted disease of ovary, 236.
Hydatid cyst in pelvis, 186.	Fluctuating tumour of uterus, 327.
Extra-uterine pregnancy, 213.	

By this arrangement the student has at once presented to him all the diseases which may occasion a fluctuating pelvic tumour; and on turning to each in succession, he has an opportunity of considering to which he must refer his particular case. It is certainly a very useful series of tables, and has been carried out with great labour and accuracy, and is calculated to afford the greatest assistance to every practitioner in those obscure cases of abdominal disease so often presented to him.

Provincial Medical & Surgical Journal.

WEDNESDAY, AUGUST 18, 1852.

THE following letter from Dr. OGLE, relative to the proceedings at Oxford, will be read with the respect which the position of the writer demands:—

To the Editor of the Provincial Medical and Surgical Journal.

DEAR SIR,—I feel myself bound to address you on the matter of the report of the proceedings of the Provincial Medical and Surgical Association, at Oxford, and of the Editorial Article relating to the same, made in the last number of your journal.

The expediency of change in the arrangements under which that journal is edited and published, and the seemliness of effecting so important a change on the strength of so small a majority, are questions clearly distinct from that now before us, and I consequently pass them without further notice; but as regards the mode in which the question of such change was determined, I take leave to assure you that you have been erroneously informed. I do not doubt the general accuracy of your reporter, nor have I it in thought to insinuate the slightest distrust of his integrity. Amid the confusion it may well have happened that he misapprehended the course I thought it advisable to adopt; but in contradiction of his report, I unhesitatingly aver that the "original motion" was put to the meeting. Looking at the motion and to the amendment, and taking into consideration the circumstances under which they were respectively proposed, I thought it desirable that the division should be taken in such manner that the sense

of the meeting should be declared at once on the point really at issue; and with such purpose I directed that those who supported the amendment should take seats on the one, and those who were for the original motion on the other side of the house. Further, some gentlemen, asked of me aloud, from the centre of the house, whether the arrangement was understood to be such as I have here described it—an inquiry which I loudly and explicitly affirmed. Moreover, I directed all parties who were neutral in the matter, to withdraw, together with the strangers, into the adjoining room.

It possibly may be objected that some might have been disposed to vote against both the original motion and the amendment, and that, consequently, it was informal to put the question in the manner I did; but whatever may be the weight of such objection, speculatively, surely under the circumstances of the case, no one will contend that it can claim, practically, any consideration at all. I am perfectly sensible that, for the just regulation of debate, it is advisable to adhere to forms, and possibly my want of experience in such matters may have occasioned me to stray from the usual course of proceeding; but no one objected to the arrangement I proposed, and certainly no one who voted for either the original motion or the amendment, can take just ground for complaint that he had not opportunity of recording his vote against each of them separately. Again, motions were subsequently made, and carried, which implied the concurrence of all parties in the declaration made from the chair, "that the original motion was carried." Among them was that of the appointment of the Committee, previously nominated by Mr. Nunneley, which (with approved exceptions and additions,) was not merely "*understood*" to be appointed, but was regularly put to the vote, and confirmed. I maintain, then, that the original motion was (together with the amendment,) fairly, and, as I conceive, regularly put to the meeting, and I shall, consequently, feel myself bound, in the impartial discharge of my duty, to uphold by my voice and authority, (if any,) the option on which the majority decided, however much I may individually regret that decision.

With compliments, &c.,

Believe me, my dear Sir,

Ever yours faithfully,

J. A. OGLE, M.D., &c.

Oxford, August 9, 1852.

After attentively examining Dr. OGLE's communication, we are more than ever convinced of the informality of the proceedings relative to the *Journal* at Oxford; for previous to the President's explanation, we could only reconcile the conflicting accounts of the various reporters by supposing that Dr. OGLE had received the first abortive attempt at a division as conclusive against the amendment, and then had considered the second division (by separating the two sides of the house) as affirming Dr. COWAN's motion. This supposition is, however, set at rest by the above letter, which fully bears out our assertion that "we are just as if nothing had been

done at Oxford, *quoad* the change of plan of publication."

We write this advisedly, for we submit, (with all due deference to the President, and, we need scarcely say, without impugning the fairness of his intentions) that it is neither formal nor fair to put the motion and amendment in the manner described by him. That it was not formal, every one, even Dr. OGLE himself, admits, and that it was not fair is quite clear, when we come to consider that under this arrangement the votes of those who are opposed to both motion and amendment could not possibly be taken. In order to obtain a fair division on the original motion, it was necessary that those who had been directed to withdraw as neutral on Mr. NUNNELEY's amendment, should have been allowed an option of voting on Dr. COWAN's motion, which the mode adopted completely prevented.

In support of this view we may instance the divisions on Mr. COBDEN's amendment on the Militia Bill, in which the majority for Government, on putting the original motion, was 219 to 85, whereas the amendment had just been previously lost by 285 to 76.

With regard to Dr. OGLE's directions being so loudly affirmed as to be understood by all, we can only appeal to the reports in the *Medical Times* and *Lancet*, in the former of which Dr. COWAN's motion is said to have been carried by a majority of two, whilst in the latter, Mr. NUNNELEY's amendment is described as lost by the same number; yet in neither of these is a word said as to the peculiar directions of Dr. OGLE; the fact is, that the confusion was so great that we are not surprised at any mistake which might be made.

But Dr. OGLE completely misunderstood the gist of our observations in our last number. We have not maintained that the one hundred and twenty gentlemen who voted are not bound by the proceedings, whatever they were, as this is entirely a distinct question; but we asserted in our last article, and we do so now, without fear of contradiction, that *the members generally are not bound by the proceedings at Oxford, because they were informal*. This, when relating to a question of property, is of some importance, as those who now have the direction of the publications are liable to the whole body, when properly assembled, if they have suffered any change of management to take place, unless

they are able to show that the formalities necessary to warrant such a proceeding have been gone through. Of course it is for them to consider whether such has been the case, and if they come to the conclusion that the proceedings were conducted with all due form, they will have only to resign their powers into the hands of those so appointed. Indeed we should scarcely have returned to the subject of the division at Oxford, but that in the first place our respect for the office of President, as well as for the distinguished individual who fills it, demands our consideration; and in the second place, it is necessary to protest against this mode of proceeding being hereafter adduced as a precedent. Our reason for this course is, that we understand that Dr. COWAN's notice of motion was not given as required by Rule 19, three months before the Anniversary Meeting. It appears that the Anniversary Meeting was officially announced in this journal on the 31st of March, nearly four months before the meeting at Oxford, while Dr. COWAN's notice was not sent till the 5th of May; so that there cannot be the slightest doubt that the whole proceedings based upon it are contrary to law. The Council will therefore have a much easier task than we anticipated, since if the above statement should prove to be correct, of which we have not the slightest doubt, the Council will be stopped at the very threshold of their inquiry, by an informality which admits of no explanation. The 19th Rule is imperative in its nature, and if the laws of the Association are not strictly maintained, farewell to all attempts at order or regularity.

We have the less reason for regret at being compelled to omit the valuable suggestions and opinions of our numerous correspondents, from whom we have received a host of letters on the above subject, some at great length; of these we have only room for those of Dr. WILLIAMS and Mr. AMYOTT, but they may be considered to embody the sentiments of the others. Several gentlemen, including Mr. PHILBRICK and Dr. DAY, have made the same suggestion as Dr. WILLIAMS, namely, to allow all the Members of the Association to vote by proxy at once. This would, it is true, virtually settle the question, but would be open to the charge of want of formality. The matter must still come before the Council, and they only can, and indeed must, decide upon it.

Medical Intelligence.

(From our own Correspondent.)

LONDON, AUGUST 16, 1852.

It is not an easy task at this period of the year to pen a lay article *de omnibus rebus et quibusdam aliis*, for the recess of Parliament has been followed by that of the profession, and physicians and surgeons, after toiling hardly during the winter, spring, and summer months, are now scattering in all directions, and seeking a holiday, wherever taste, pleasure, health, or duty may direct them; but little is done consequently, and even that little is scarcely worth recording.

Notwithstanding the decided character of the resolutions passed at the Brighton meeting of the Association, there are occasional rumors that some medical men do not hesitate, or scarcely hesitate, to meet professionally, the practisers of homœopathy, of course merely to ascertain the existence and character of a disease, or to confirm the diagnosis already made, the homœopath being then permitted or left to treat the malady, the nature of which he could not recognize, according to the approved principles and precepts enunciated by Hahnemann and his disciples. When a legitimate member of the profession has been decoyed stealthily into a consultation, he supposes the person he is about to meet to be, like himself, a true and honest practitioner of medicine, according to the principles usually taught in the schools; but if, finding at the time, or afterwards, that he has been entrapped, he indignantly denounces the cheat, and refuses to hold further intercourse with the empiric, we may pity him for his misfortune, and must acknowledge him to be still strictly entitled to his legitimate status and honors among us. Such a case has occurred of late years, but the unfortunate consultee was not deemed to be free from participating in the wrongdoing of the consultant. Fierce and angry accusations were launched against him, and for some time he felt the sad results in a considerable diminution of his consulting practice. Some, however, are bolder than he was, and recklessly declare that a consultation with a homœopath is not beyond their province, provided they participate not in the very act of prescribing homœopathically.

Although some very gross cases connected with that mode of "practising" have occurred, and been exposed from time to time, it cannot be said that the heresy is failing in the estimation of the public. The plausibility of its professors, and the speciousness with which they urge their charges against legitimate medicine, exert a certain influence for a time on the public mind; and, although some of those who have tried the system, have abandoned it, from its utter inutility in repelling the attacks of serious disease, fresh victims are readily obtained, their minds being imposed upon, and deluded by the boasting details of cures effected by the system *à la Holloway ou Morison*, "when the most eminent in the profession had declared the disease to be utterly incurable;" or, "when the patient had been dismissed without benefit from three or four metropolitan hospitals, and from some half-dozen provincial ones." By old hacknied boastings such as these, and by the specious reasoning urged in favor of their dogmata, greatly influenced also by the desire to avoid taking large and continued doses of drugs, persons of education, and even of considerable acquirements, fall into the trap, are completely gulled for a time, and for as long as the delusion endures, swell the train of the "learned professors," or may even vibrate between the two systems of homœopathy and hydropathy.

Among other instances of the spread of this delusion for the present, may be mentioned the fact, that a physician in a large practice at the West End, chiefly

among the nobility, has experienced latterly a considerable reduction in his yearly income, to the amount of some hundreds, resulting from the falling off of several of his accustomed *clientelle*. It is not an unusual thing for the educated classes especially to take up with the heresy for a short time, captivated by the delusive argument used in its favour, and probably also by the excitement attending the having recourse to that which is to them a novelty, more especially since the stir made in the ranks of the profession against it, and the absolute separation of the withered and dead branch from the tree of medical science. It is, indeed, much to be feared that the fierce and determined onslaught made on its professors, has contributed not a little to its present increased popularity; for the public, looking upon it as a mere quarrel among the doctors, naturally lean to those who seek for, and obtain the greatest notoriety, and in that no one can deny that our opponents have the palm.

Meanwhile there is an anecdote current which exhibits their pretensions to science and to minute accuracy in semeiology and the effects of drugs in a ridiculous point of view. At a public dinner, one of their principal authorities—to borrow a word from our continental brethren—assisted, whom we shall designate for the nonce as Dr. X. After partaking freely of many of the delicacies which were before him, the doctor, who is somewhat of a *bon vivant*, and understands the art of carving to perfection, was called upon to cut up a turkey for the benefit of all around. This duty having been properly performed, Dr. X. was observed to place a tit-bit from the bird in his own plate, but studiously to avoid the seasoning, which, however, he had liberally dispensed to the other guests at the table. This peculiar abstinence elicited a remark, and the question speedily followed as to the why and wherefore Dr. X. did not ornament his plate with the seasoning, it being so agreeable an addition to the bird's flesh. Assuming a serious and grave look, the doctor shook his head most sagely, and declared "he did not partake of it; it was most dangerous." "Dangerous! how? what harm can a little seasoning do you? Come Doctor, take some; you'll enjoy the turkey much more if you do." "Much obliged, my dear sir," was the reply of the alarmed homœopath, "but indeed I dare not; it contains parsley, you know, and that may cause a serious COLLAPSE!" To those who had watched the prowess of the learned doctor at the dinner, and the energy with which he had despatched fish, flesh, and fowl, washing them down with repeated libations of champagne and other rich wines, the source of the anticipated collapse was very clear, and quite independent of a very small modicum of parsley.

Various schemes have been proposed for the employment, for useful purposes, of the balance of the money, amounting, it is said, to £150,000, realised by the Great Exhibition; but the plan now proposed, which has been attributed to His Royal Highness Prince Albert, transcends them all in utility and excellence. It is said that the Prince has proposed to found a grand Industrial College,—a home for the arts and sciences,—an University of science, literature, and fine arts. It has even been asserted that the Prime Minister is prepared to make a national endowment in its behalf, worthy of the country and of the interests to be served. It is a part of the scheme to bring together the National Gallery, the learned societies, the Society of Arts, the School of Mines, and all other institutions having a close connection with science and the arts; a reform and re-arrangement long and earnestly demanded by all thinking *savans*. The whole is to be arranged with a view to practical results; science and industry, for the first time in this country, being brought together in close relation. How much better is a vast, original, and extensive plan like this, for the advancement of science and literature, than those meagre and paltry arrangements by which the total amount was to be

frittered away in small sums;—here a full hundred for endowing a professorship, there a similar sum for establishing reading-rooms, and there again for forming a museum, an atheneum, a club-house, or a lyceum, until the total £150,000 might have been spent in ways and means, to the satisfaction of a few jobbers, but not for the interest and benefit of the many, nor of the country at large. The plan is truly original in its whole, although a part thereof was proposed some years since; and a hope then existed that it would be carried into effect. We allude to that part of it which proposes the embodiment together of the learned societies. It was proposed that all those societies which had natural history in some one or other of its branches for their basis, such as the Linnaean, the Botanical, the Medico-Botanical, the Chemical, etc., etc., should be united; the several societies being, as it were, sections of the whole, with each its separate staff of officers to manage their own pecuniary affairs; all meeting in one house, and contributing a certain proportion to the general expenses. Why so comprehensive and so useful a plan fell through we never could learn; but we presume it arose from the difficulty of getting so many persons to act usefully together, and from the jealousy of some of the officers, who perhaps were unwilling to officiate for a section, when they had previously been, and were then, in office for an independent society. The sooner the plan now in contemplation is carried out in its entirety the better for science; as some, at least, of the learned societies are involved in considerable pecuniary difficulties, and may be compelled, for want of means, to close altogether, and to dissolve if not thus assisted. This has been the case indeed within the last eighteen months, as regards one of the above-named societies, which, after a career of about thirty years, during which the chief men of science in this country, on the Continent, and in America, have been enrolled in its list of members, ordinary or honorary, has been compelled to retire from the arena of sciences, overburdened and borne down by a weight of debt left its Council as a legacy by a former official, which debt hung like a mill-stone round its neck, until it was overwhelmed and lost in the deep waters. Had the plan we have alluded to been carried out, this sacrifice would, in all probability, have been prevented.

The latest mortality records for the past week state the proportion of deaths within the bills to be,—from diarrhoea 213; and from cholera (English of course) 21; 16 children, and five persons above the age of fifteen died from the last-named disease; 192 children and 21 adults from diarrhoea; sixteen of the cases of cholera occurred on the north, and five on the south side of the Thames. Meanwhile a far more fearful visitant is rapidly approaching, for the third time within twenty years: the deadly epidemic of Jessoré is about to assail the inhabitants of this empire; and but little, if anything, has been done to disarm the disease of its awful powers, and to render the inhabited places as wholesome and healthy as they ought to be. Following the same course as in its previous visitations, the cholera has entered Europe through Russia, and, after lingering there for several months, and committing frightful devastations among a most uncleanly people, it has passed into Russian Poland and invaded the kingdom (formerly the principality) of Warsaw, in the capital of which from fifty to sixty lives are daily sacrificed, a holocaust on the altar of filth—personal and municipal—drunkenness, and all evil passions, and consequently of epidemic disease. In Kalisch, also in Russian Poland, a town of considerable commerce and opulence, the mortality attendant on the disease has been very high indeed; and in Posen, four-fifths of those attacked perish. Since the appearance of this pestilence in Russian Poland, it has broken out in Dantzic, and there its ravages, it is to be feared, will be most dreadful and extensive. Everything betokens that it is hastening

hitherwards on the wings of the winds; and yet this overgrown and over-peopled world-metropolis, is in no respect better prepared to stay its ravages than it was in 1849, and scarcely more so than in 1831-32, when it was encountered in England. We have, to be sure, a General Board of Health, with a paid medical member, and a legal member, who is in truth its dictator; and they have published some neat blue books on quarantine, cholera, &c., but in no other way have they been of service in affording us the means, under Providence, to quell the ravages of the destroyer. The atrociously filthy condition of the habitations in which the poor herd together remains much the same; fever is as prevalent in their districts as ever; and although the wretched beings are constantly decimated by disease, the vacancies thus made are rapidly filled up, and the crop for disease and death to gather is as large, or larger than ever it was.

The malignant conjunction of the stars, which, as the astrologers have it, is so productive of disease, is not confined to the human race; epizootics have been very fatal throughout the kingdom, so much so indeed that the Royal Agricultural Assurance Society have had to pay upwards of £200,000 during the past year, in consequence of the mortality attendant on the epizootic among the cattle. Equally unfortunate is the progress of disease amongst vegetation. The blight has again, for the sixth or seventh time, attacked the potato, and that esculent in Ireland may be regarded as almost lost, at all events in many places scarcely half the crop will be gathered in, and in some, perhaps, not that. The reports throughout the length and the breadth of the land, are, that unless by Divine Providence, a larger amount of the potato be saved than is expected, another famine, followed by pestilence, may be anticipated. The blight has shown itself also in many places in England, but not so extensively as in the sister country, as that tuber is here only regarded as an adjuvant to the disease, ease, and not as the principal and sole food of the peasantry. Besides the potato, the beans have been more or less affected, and the vineyards in the south of France, in Italy, in Spain, especially in the neighbourhood of Malaga, and in Portugal and Malta, have been so seriously diseased as almost to involve their utter loss. Burgundy has in a great degree escaped; but, *en revanche*, in Madeira, it is said, all the vineyards have been involved in one common destruction, so that that celebrated wine, formerly so great a favourite with the gentry, may be as thoroughly lost to the epicure as are several of the more favourite wines of the ancients. The inhabitants of Madeira have petitioned for leave to cultivate tobacco, to repair the pecuniary loss sustained by the destruction of the vines. John Bull will feel vexed at the loss of the Portuguese wines; but as it is a well-known fact that more Port (!) is sold in London in one year, than is manufactured in Portugal in three, he may still obtain his "London particular," as we believe the logwood tree is still uninjured. The disease by which the vines have suffered, is called the "MAUGRA," or "ORDIUM," and it appears at first like small dust on the green berry, causing the fruit to burst, and ultimately to become putrid. It is said that a deep incision in the trunk of the vine, near the root, has been extensively tried in Savoy, and everywhere with success in curing the disease. So simple a remedy ought to be made extensively known in the vine-growing countries.

This long catalogue of ills affecting man, as well as the animal and vegetable kingdom, may be closed by the announcement that an unknown disease has attacked the currant plant, which blackens and rots the fruit in one night. The same malady—a variety, probably, of the Mauga—has also attacked the currants of the Ionian islands, and it is believed that not one-fourth of the crop will be preserved. Sad news, again, for John Bull; what will he do without his port and his Christmas plum-pudding?

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted on the 30th ult.:—Joseph Fenn Allnutt, Australia; Henry Adye, Bradford, Wiltshire; Barnabus Barrett, Shrewsbury; Joseph Lewis, Cardiff, Glamorganshire; Edwin Moore, Highgate; George Puckle, Camberwell; James Lewis Sanders, Chelsea; Charles Taylor, Nottingham; Leonard, Keatley Yelf, Ryde, Isle of Wight.

The following gentlemen were admitted on the 2nd instant:—Frank Lane Bindley, Burton-on-Trent, Staffordshire; Thomas Coghlan, Cork; John Coogan, Cork; William Henry Cufaude, Acle, Norwich; Walter Humphries, Cork; Samuel Job, Bawtry, Yorkshire; William Lichfield, Southampton; Joseph Beauchamp Matthews, Weston-on-the-Green, Oxon; Thadeus Leyden Molony, Ennistymon, co. Clare; Daniel Hack Tuke, York.

The following gentlemen were admitted on the 4th instant:—John Edmunds, Bangor-Iscoed, Flintshire; Joshua Lever, Bolton-le-Moors, Lancashire; John Noble, York; George Bell Poppelwell, North Shields, Northumberland; Lewis Robert Ramond, Lower Sydenham, Kent; Richard Patrick Burke Taaffe, London; Frederick Edmund West, Dublin.

The following gentlemen were admitted on the 6th instant:—Thomas Bray, Dublin; Garret Butler, Dublin; Henry Richard Foquett, Lucknow, Bengal; James Hurd Keeling, Edinburgh; Robert Leys, Banchoory, Kincardineshire; Charles Benjamin Mosse, Carlow; Malim Sharman, Birmingham; John Mortlock Tronson, Dublin.

The following gentlemen were admitted on the 9th instant:—Walter Bernard, Cork; Hallam Moore Dixon, Cape of Good Hope; William Archibald Garrington, Portsea; Alexander Robert Hudson, Fermanagh, Enniskillen; George Lawson, Forest Hill, Sydenham; James Henry Lewis, Kinsale, co. Cork; William O'Connor, Munster; Edward Tenison Ryan, New York; Henry William Spry, Trinidad Place, Islington.

THE FELLOWSHIP.—The following gentlemen were admitted to the Fellowship on the 10th inst:—Peter Hinckes Bird, Spring Gardens, diploma of membership dated May 19, 1848; Cornelius Black, Chesterfield, May 3, 1844; Archibald Prentice Childs, Bungay, August 10, 1849; Harvey Ludlow, Paternoster Row, June 22, 1849; William Scovell Savory, Charterhouse Square, Dec. 8, 1847.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 29th July:—Matthew Corner, Whitby, Yorkshire; Charles Thick Eves, Cheltenham; Noah Fox, Nottingham; Augustus Brabius Webb Greatrex, Eccleshall; Charles Hooper, Buntingford, Herts; Fredererick Francis Ormond, Plymouth; George Simpson, India; John Cuthbert Whaley, Kilburn.

Gentlemen admitted members on the 5th August:—Edward Hare Bromley, Rippingale; William Adcock Burrows; Charles Moore Jessop, Bilton Hall, Yorkshire; William Edward Robbs, Grantham; Henry Little Sequeira, London.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN.

At the August graduation at this University, the degree of M.D., was conferred on the following gentlemen, who were examined in the various branches of medicine, and found duly qualified:—John Morgan Bryan, Northampton; Thomas Collins, Aberdeen; Charles Henry Dunhill, London; John Boon Hayes,

Birmingham; William Aston Lewis, London; Peter William Long, Ireland; Thomas Morris, London; James Orwin, Salop; James Hollins Pickford, Brighton; William Callender Tidy, London; Daniel Henry George Wildbore, London; James Goodchild Wakley, London.

OBITUARY.

July 27, aged 63, Erasmus L. Devonald, Esq., surgeon, of 71, Great Tichfield Street, and 6, Howey Place, London.

August 6, at Wooton-under-Edge, Robert Bailey, Esq., surgeon, aged 74.

August 8, at his residence, Pucklechurch, Gloucestershire, aged 66, John Champeny Swayne, Esq., M.R.C.S., late of Berkeley Square, Bristol.

August 3rd, at Brighton, after a severe illness, Richard Ebsworth, Esq., surgeon, of Shillingford, in the 42nd year of his age.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

In addition to the names published in the last *Journal* as being appointed of the Council, that of WM. MATTERSON, jun., Esq., Local Secretary for Yorkshire, was *accidentally omitted*.

W. P. BROOKES, Esq., was also appointed Local Secretary for Cheltenham, and

ELLIS JONES, Esq., Local Secretary for Liverpool.

In consequence of the great accession of new members during the present year, the first eight numbers of the volume now in course of publication are out of print.

J. P. SHEPPARD.

Worcester, August 17th, 1852.

Secretary.

ERRATA.

In our report of the Anniversary Meeting, at page 404, column 2, line 14, the following correction is required:—For “read by the House Surgeon, Mr. Hussey,” read—“read by E. L. Hussey, Esq., F.R.C.S.E., one of the Surgeons to the Infirmary.” The paper consisted of a statistical account of all operations performed in that (the Radcliffe) Infirmary for some years past.

The following error also occurred in Dr Whiting's speech, in proposing a vote of thanks to Dr. Wilkinson, after the reading of the Address in Medicine:—Page 404, col. 1, line 9, for “philosophical lectures,” read “physiological lectures;” line 11, for “the general thanks of the town,” read “the thanks of many in the town.”

TO CORRESPONDENTS.

Communications have been received from Dr. Oke, Mr. Martin, Dr. McWilliams, Justice to Worcester, Mr. King, University of London, Publicus, Mr. Paul, Nil Desperandum, Dr. Whiting, Dr. Garstang, Mr. Harriks, Mr. Roe.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

LECTURES
ON THE
DISEASES OF CHILDREN,

DELIVERED IN THE

Chatham Street School of Medicine, Manchester.

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesh, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesh; Fellow of the Imperial Society of Vienna, etc.

LECTURE XII.

Simple Primary Fever Continued.—Febrile headache, its distinction from meningitis, and management. Gastric disorder as proper to any primary paroxysm; symptoms, indications for a purgative or an emetic, their proper choice; occasionally disagreeable effects of hyperæmesis and overpurging; how to be counteracted. Further course and description of the primary fever, its early and happy termination. Reserve with remedies. Ephimera. Further course, above thirty-six hours. Objective description of the hypersthenic stage, comparatively with that in adults; complications; transitions. The asthenic stage. Pathological changes.

GENTLEMEN,—In every primary fever the head and abdomen attract our first and careful attention.

Headache, a most constant companion of fever, easily appreciated and less alarming in adults, appears more obscure and threatening in children, because they cannot give us *symptoms by words*, so as to facilitate the distinction from congestion or meningitis. It manifests itself in the child in different degrees, when lifted up in the arms of the mother or nurse, by its difficulty or inability of holding its head upright, by leaning it on the shoulders, along with simultaneous appearance of some perpendicular wrinkles on the forehead between the brows, languor of the eyes, falling of the upper eyelid, and plaintive moaning; considerable degree of heat on the front. The little patient keeps the head rather steadily and quietly in the same posture, without restlessly moving it; and all the above symptoms are equable for some time. Recollect what adults say in this state by words, and thus you will have the whole more clearly before you. Sometimes they complain of acute, at other times of dull pain, on pressure, or giddiness. These differences it would be difficult to trace in a child; we must content ourselves with knowing that there is headache present, and judge of its importance according to the degree and weight of the above symptoms, comparatively with the general state, or some important local affection. In a little child we must be very careful, because painful abdominal affections may cause dropping of the head, moaning, and frontal wrinkles, just as if the head itself were suffering pain.

As to the nature of febrile headache, it is but an old superficiality, which always identifies pain and heat in the head with congestion. We know little of the nervous

fluid yet, so plentifully developed in the brain, and of the laws of its circulation. The fact, however, stands firm, that paroxysms of intermittent fever present, as to heat and pain, a severe kind of headache; and still there is little fear of meningitis. Nervous headache in delicate ladies manifests the same severity, with the same exclusion of meningitis. In both cases, generally, leeching does not cause relief. Thus we may be allowed to establish a febrile headache of the nervous kind, perhaps a congestion of the nervous fluid causing pain or spasm. As to congestion of blood in the brain, which, of course, may also be connected with febrile headache, just as it complicates, occasionally, even hysterical headache,—this, in the height of fever, I do not know how to distinguish exactly; I believe, however, that in the case where congestion is the principal affection, there will be the appearance of a higher degree of heaviness of the head, and of the languor of the eyes and eyelids, more oppressive somnolence, or even soporous sleep, high heat on the forehead, but less of the extremities, and less moaning. And in the case of decided inflammatory action in the envelopes,—that is, in the first stage of meningitis, there will be, with a given degree of heaviness and heat, less sleepiness, and, instead of steady posture, even restless rolling and pushing of the head here and there, and a more lively expression of pain, with occasional startings and screamings. The second stage is too clearly characterised to admit mistakes.

As to eclampsy, during the stage of febrile heat, I have been satisfied, by many dissections, that it is less frequently a symptom of the first stage of meningitis, than the effect of different febrile and non-febrile, gastric, or other disturbances acting upon the nervous system, consequently there is a more natural combination between eclampsy and headache of a nervous or spasmodic kind, than between eclampsy and meningitis. Gastric disorder, during fever, I believe frequently may be the simultaneous effect with headache, and is, perhaps, too generally considered as its source; at any rate, whenever fever, and along with the signs of headache, gastric disorder is well ascertained by its local and functional symptoms, we may be almost sure of the non-inflammatory nature of that headache. Tense epigastrium, for example, and furred tongue, are frequently connected with nervous, but never, I believe, with inflammatory, headache. Moreover, consider the following comparative analysis:—A paroxysm of fever, with headache, in order to make us apprehend acute primary congestion, or meningitis, must be rather intense. Now, if this be the case, the temperature of the skin, in fever, will be high, and so all over the body, the highest on the epigastrium; and the pulse of a little child between 150, and 170, or more. And all these conditions, unitedly, will be the more expressed in high gastric fever, in which, also, the highest degrees of sympathetic headache do occur; whilst in the case of active congestion or meningitis, generally, and proportionally to other symptoms, there is less heat and dryness. Hands and feet frequently even cool in comparison with the forehead, and in many cases the pulse less frequent.

Vomiting of bilious liquid may be the effect of simple fever or febrile headache, as well as of meningitis, and in both cases the epigastrium is soft, consequently this symptom has in itself not much diagnostic value.

Acute hydrocephalus, (anatomically different from genuine meningitis,) in the great majority, does not set in so suddenly, and under that sudden appearance of high fever, as we have described it above; a careful observer will, therefore, be less exposed to confound the first stage of hydrocephalus with the simple febrile head-symptoms, than the first stage of meningitis.

In conclusion, I have been satisfied, too, that simple febrile headache is far more frequent than meningitis or hydrocephalus.

All these different diagnostic points, of course, taken *singillatim*, admit of exceptions, and cannot be trusted by themselves; considered, however, in relation with each other, and many special circumstances of the case, they are of some value. I nearly forgot to recommend great care and application, in accustoming your hands to distinguish the proportion between the heat on the forehead and on the epigastrium; this, I find, is important. In congestion or meningitis, the heat of the epigastrium is less. In medical practice there are few points of greater difficulty than that in question. Even in adults we labour sometimes under the ambiguity between the nervous and congestive character of headache. Nor can it be denied, that in many instances congestion may join spasmodic pains; or, that headache, which at first was but an effect of nervous disorder, proper to fever, may become congestive. The question will be,—shall you, in a given case of recently-developed primary fever, under the mentioned appearance of the head, resort to energetic leeching, or wait, or adopt some milder means? By the industrious and clever application of your senses and mental powers, an increasing number of patients will by and by increase your discernment, which I only wish to assist by giving you some facilitating directions.

There are, however, those intermediate and undecided cases, in which we cannot get rid of the ambiguity between simple headache, and congestion or meningitis. This has been the case frequently with me, though I have seen thousands of them; and it will be the same with you. In similar emergencies I can but recommend you the following conduct:—Consider well the constitution of the child; is it strong? then, after you have freely moved the bowels, and energetically used cold fomentations, without effect, leech it; in the contrary case, wait a little longer before you take blood. And, in spite of the apparent vehemence of head-symptoms, abstain from taking blood, if you have before you one of those scrofulous habits, with thin legs, and a large, flat, angular skull, or a rachitic or a very delicate decidedly nervous child. These are all exceedingly liable to febrile disorder and headache, but not to inflammation, and are injured by loss of blood.

Cold fomentations on the head, abundant cold water and sugar to drink, and perhaps a cooling injection, (of thin barley decoction, with sugar and oil,) will best answer the indications of that hot stage, with headache,

within the first twenty-four hours. Sinapisms are improper at that stage for tender infants; they might increase the fever, by irritating their tender skin. If, then, the general febrile symptoms continue longer than twenty-four hours, with unabated heat, pulse, and thirst, and heaviness of the head persists, or increases, together with languor of the eyes, and heavy moaning, restlessness, and painful crying, or occasional outcries, where no remarkable gastric derangement is discoverable by the above-mentioned signs, and after the bowels have been moved, then the indication of leeching acquires more weight and consideration.

Your call in these cases ought to be repeated after a few hours, and again the examination be performed with the same minute care as described in my last lecture. Do not forget to particularly investigate mouth and throat, outside and inside; and offer the child some water and sugar to drink, carefully observing his swallowing movements; and if you see they are not free, as if checked under expression of pain—in one word, if you find the slightest signs of pharyngeal irritation, with a degree of dryness in the mouth, do not hesitate to order an emetic. This is one of the important points of children's practice. In hundreds of similar instances I have ordered the emetic where I should not have felt pressed to order it to grown up people; the reason is, the greater frequency, rapidity, and danger of laryngeal and pharyngeal inflammations of children.

Gastric disorder, to a certain extent, is almost a constant effect of every kind of fever. I understand here that degree characterised in adults as follows:—want of appetite, dryness and bad taste in the mouth, some fur on the tongue, sensation of fulness in the epigastrium, sometimes eructations, and more or less degree of headache. The same degree will appear in infants, with less dryness and fur of the tongue; and of the bad taste we get no accounts at all; consequently the whole is more obscure than in adults. For this reason I may be allowed to rely more upon the palpable *tense state of the epigastrium*, and add the increased *heat of that region*, which will be found the higher in gastric fevers, on the contrary, less than on the forehead, in cases of secondary cephalopathic gastric disorder.

That degree of gastric disorder (according to what we observe in adults) frequently vanishes by itself as soon as the paroxysm ceases, and along with the headache; sometimes, however, it is connected with a more material condition of abnormal mucous and bilious secretions, and affects more strikingly the head.

Gastric disorder, speaking in general, is in primary fevers of children of not so important and urgent weight as the state of the head; but frequently headache is dependent on the former. In other cases, again, gastric disorder arises from the affected brain. It is, therefore, of the highest importance to distinguish *idiopathic gastric disorder* (of the above description) from the sympathetic and the cephalopathic one. Now, in the great majority, the latter will appear with a flat, or at least soft, abdomen, and moderate heat on the epigastrium. Real gastric disorder, on the contrary,

will be connected with a bloated or tense epigastrium and great local heat, more than on the forehead. Gastric symptoms of the kind do not require so much haste as direct head symptoms. But if, after about twenty-four hours, particularly if during a remission of heat and pulse, the child shows no desire for the breast or food, and the bowels are rather confined, then I recommend a mild *liquid* purgative, choosing one of those mentioned in the eighth lecture.

More is requisite to determine the indication of the emetic. One I have mentioned before, *i. e.*, signs of angina, as urgent, even at the earliest stage of fever. With the exception of this there will seldom be so great an urgency. If, however, after the first twenty-four hours, and under the remission of fever, the child manifests aversion to food or the breast, with little thirst (for breast or water);—if the mentioned signs of headache are present without costiveness, yet a tense state or *fulness of the epigastrium*, with a higher proportion of heat of *this* region, dryness in the mouth, sometimes vomiting of badly smelling liquids, or a little bile;—if, under the presence of these symptoms, the abdomen, cleverly explored, does not manifest signs of inflammation, then we order the emetic with more than common confidence in its usefulness. Be it, however, a purgative or an emetic that we give, we must carefully watch its effects, particularly on the head symptoms. Be the effects positive or negative, good or bad, they will give us probably some instructive hint.

The emetic, as well as the purgative, in order to secure good effects, must be properly adapted to the age and constitution of the child, according to the principles exposed in the eighth and ninth lectures. In high fever both must be given in liquid form. For a tender child, a simple infusion of *ipeacuanha*, about a scruple to one ounce (in preference to tartarized antimony); and castor-oil, if purging be required; because an improper effect of the kind might seriously disturb the course of the fever; protract or impede the critical molimina, or a cutaneous eruption, if it has to come; cause an asthenic turn of the fever, or even sudden collapse. Both hyperæmesis as well as overpurging may cause these bad effects. This I have seen, particularly from small and frequently-repeated doses of tartarized antimony, which sometimes, instead of causing the intended vomiting effect, after a while of apparent inefficacy, produce profuse purging of whitish serous liquids, under which the temperature of the skin decreases, and the frequency of the pulse increases rapidly towards 170, 200, and more. *Turgor vitalis* lessens visibly on face and limbs, the eyes sink into their hollows, and the nose and fingers get cool. The child utters now and then feeble moaning sounds. The countenance offers, more or less, the print of the *facies Hippocratica*, or of what the eminent Marshall Hall so truly depicted under the name of hydrocephaloid disease.

Solutions of neutral salts have sometimes the same disagreeable effect upon young infants in fever. Whilst heat is at its height, these remedies frequently act very slowly; thus you give dose after dose without apparent

action, and then, at once, under a period of remission, the excessive effect appears. It was a *Hippocratic rule* not to give evacuants during the height of the paroxysm.

You must bring early help in cases of collapse. If the purging action has nearly ceased, and debility is not on the highest scale, you may content yourself with a teaspoonful or two, every half hour, of a hot infusion of camomile (prepared always fresh, and, if possible, of that quality of flowers recommended in the ninth lecture); and let the abdomen and members be rubbed with hot camphorated brandy. If purging still persists, give once or twice (at about two hours' interval), besides brandy, one to three drops of *Sp. Ammon. Arom.*, and from one-eighth of a drop to one drop of *Tinct. Opii*.

In the case of hyperæmesis, and when sickness continues, order, instead of the hot infusion, small doses of a simple effervescent mixture, with some stimulant drops of the lightest kind, *f. e.*, liquor Hoffmanni, and use the mentioned frictions. Thus we endeavour to restore the heat again, and set the fever right and apt for a good crisis.

In ratio of the debility and tender age you must be the more careful with the doses of opium. In similar cases I have seen most injurious narcosis ensue after one dose of about half a drop, in children under one year.

Thus far my remarks, as you are aware, concern the management of *simple primary fever within* the first thirty-six hours from its beginning. You might make in that time repeated calls; but be not too eager with physic. The higher the heat of the skin, with a proportionally moderate pulse (130 to 150), and moderate head and gastric symptoms, the less reason for any medicine. Hundreds of these cases have recovered under my care without a single drug; and hundreds of them I have noticed who got worse by medicines, under the innocent predicate of cooling, tempering, solvent, saline, mixtures, or emulsion with nitrate of potass. I can but refer here to what I have said in the eighth lecture on the use of antiphlogistic and cooling remedies in the tender age. The cooling effect of those remedies is obscure, but their deranging of the delicate stomach very probable. Besides the mentioned management of the head and bowels, if necessary, reduction in the quantity of milk, and frequent supply of small quantities of water with sugar, every half hour or hour; this is the best plan for nurslings. Above the first year, if you think you must prescribe, besides that, I recommend half a drachm of citrate of potash, or half a scruple of tartaric acid to two ounces of water, with two drachms of syrup of lemon; also light lemonade to drink.

If then, by prudent management, and under that kind of harmonious proportion between the principal symptoms (alluded to in my last lecture), you come to the second day, perhaps before that day is past, perspiration or sweat will have put an end to all febrile symptoms.

This is *ephemera*, *i. e.*, a sudden attack of primary fever, with or without precedent perceptible rigor, terminating within about twenty-four hours by sweat.

This form I dare say occurs more frequently in childhood than in mature age; but the younger the child the less there is both of cold and profuse sweat; slight perspiration, on the contrary, does easily come. A fever like that may, however, with little or no remission, and no perspiration at all, continue or increase further than the second day. You will then observe the above-mentioned principal objective symptoms in their utmost intensity; avidity for the breast; frequent but short sucking; the mouth and tongue dry, though less so than in elder children; the skin considerably hot, but turgid, and not so dry as in adults; flushed and turgid countenance, more than in adults, but the eyes more languid, occasionally shut or half shut; a restless sleep, with occasional startings and twitchings, sometimes with tremor, on the limbs and muscles of the face; the mentioned objective symptoms of headache more expressive, united with continuous restlessness and moaning; the bowels confined; urine scanty, at long intervals, and its stain more coloured than before; the pulse hard, above 160—170. To a similar group of symptoms in adults and elder children there is frequently added a degree of unmeaning loquacity, or slight delirium, which in the tender age is impossible, though there is to be observed something equivalent in the movements of the mouth, eyes, head, and limbs, and emitted sounds, difficult to describe. These symptoms, in absence of real inflammation of an important organ, express—

The hypersthenic character or stage of fever.—If the whole of these symptoms be equivalent to what authors call synocha, in adults, which generally runs a week and longer, before it passes into synochus, then I can pronounce, that synocha runs in tender infancy (under two years) but a short course towards synochus; because, under the second year the mentioned high stage soon exhausts the vital powers of them. As children grow older they are able to keep up longer and resist better that stage of reaction, or in other words, courses and stages of fevers last longer and are less dangerous in proportion to the older age.

I remember some cases of sudden death by convulsions, some others without being noticed how, at the height of the hypersthenic stage. These were all very young infants and children. The hypersthenic stage, as described, if present on the third day of fever, admits in elder children, the possibility of either ending favourably by a good crisis, or of passing into cerebral or exanthematic typhus, into angina maligna; and of the eruptions that of scarlatina may yet appear, even of a dangerous form; but the first case scarcely will happen before the sixth, and the two latter diseases seldom before the third year. In younger children a not unfrequent transition is that into the *asthenic stage*, to be mentioned further.

As to complications arising during the hypersthenic stage there are many of little degree and importance, not always even discoverable in that height of the general symptoms during life, and only few important ones. Of the latter kind, are congestion of the brain, of the lungs, and of the liver, angina, and diarrhoea.

The congestion of the brain (which is not to be confounded with meningitis) it must be confessed, is exceedingly difficult to be diagnosticated amidst the symptoms of the hypersthenic stage. You will recollect what I have said about headache; I can only add, that if you have before you a child under the described symptoms of the hypersthenic stage,—the skin hot, but the forehead more hot than the epigastrium; the hands and feet still less hot; under a continuous heavy drowsiness with moaning, but without crying out loud, with his eyes continuously shut, if taken up in the arms, his being unable to open them, his head heavily dropping downwards if not supported, the face rather flushed and turgid, the pulse (in this relation of symptoms) not above 160, and the constitution of the child not opposing congestion, then you may regard the case to be that, and act accordingly against it.

Congestion of the lungs in hypersthenic fever, according to what I have seen in some fatal cases of the kind, has been general over both lungs. There is no significant cough or sign of pain; you can merely rely upon auscultation and percussion, by which you will find in these cases, a diminution of the vesicular bruit, along with a slight degree of dulness over the lateral and lower parts of the chest.

Congestion in the liver you may detect by touch and percussion.

Pharyngeal irritation in the form of "*pharyngite erythémateuse*," with swelling of the tonsils, is the most common and important complication of that stage of fever in children. It is rare under six months, but rather frequent above two years of age. You recognize it if inspection be impracticable, by careful touch externally, and by observing the movements of deglutition at the breast, or of some water offered to the child.

Diarrhœa seldom combines with the hypersthenic stage, and if so, then it will but hasten the passage into the asthenic. Sometimes, at the height, some *bilious discharges take place*, with beneficial effect, and must not be checked.

Angina, if a great degree of swelling be present, will scarcely ever fail to be connected with the above symptoms of congestion of the brain.

The hypersthenic stage, as described, be it with or without complication, will last to the third, fourth, and seldom to the fifth day, from the commencement of the fever, the shorter in proportion to the vehemence of symptoms, and the more tender age. In infants the asthenic stage will soon follow, unless a salutary crisis had appeared within about forty-eight hours of its duration.

The *asthenic stage* in most cases, will be announced by increase of dryness along with permanent, sometimes, however, with decreasing temperature of the skin, together with simultaneous increase of the pulse to 170, 180 or more, collapsus and anxious expression of the countenance; if it be protracted a day or two the lips become quite dry, with dry fissures here and there; the tongue in young children may maintain a degree of moisture, except in the cases of gastric complication. There is great restlessness with occasional rambling.

Increase of the heat at this stage is not very common with young infants; it persists about the same degree, or even decreases.

Whenever continued fever takes this course, the danger is great, and if again, in the space of twenty-four hours, these symptoms do not change for the better, you may in most cases expect a fatal end, under a more or less rapid exhaustion of vital action, occasionally in a fit of eclampsy. In other cases the asthenic stage takes a slower and longer course, sometimes passing into a chronic and weary remittent form, ending in gradual recovery or death.

In bodies of young children, dead within that stage and time, we are far more frequently than in adults at a loss to find remarkable anatomical changes, unless you would qualify as such the variable congestions, of an active or passive character, in one part or other, or partial injections of the mucous membrane, or effusions in one or the other of the cavities, or many kinds of complicated affections. All this I saw, but variable and inessential. The blood seems not to reach in children, in acute fevers, to that degree of chemical alteration, that it does in adults, and the whole course of the fever is too short to effect such marked anatomical changes. The mentioned slower asthenic forms affect more considerably the tissues; but this is not to our present purpose. Next I will speak of the treatment.

A FATAL CASE OF HYDROPHOBIA

TREATED WITH CHLOROFORM.

By THOMAS SANDWICH, M.D., BEVERLEY.

WHETHER chloroform will prove to be an antidote for hydrophobia remains to be seen, and is an event rather to be desired than expected; but that it will procure an euthanasia is certain. In order to prevent speedy death from the exhausting effects of the spasms of the throat, and allow time for the elimination of the morbid poison in hydrophobia, it has been proposed to open the trachea. It would, however, appear from the following case that all the advantages that could be derived from tracheotomy may be obtained from chloroform, and these in a manner far more agreeable to the patient, as well as the medical attendant.

William Warden, aged 42 years, was attacked by a strange dog, and one of the fingers of the left hand was wounded, about six months prior to the outbreak of the symptoms of hydrophobia. The dog was immediately destroyed, and the wound healed so quickly that in the course of two or three days he was able to resume his occupation as a labourer in a tan-yard. On the 4th of October he applied to one of the medical officers of the dispensary, on account of a pain in the left side, which was supposed to be rheumatic, and was treated accordingly. In the evening of that day symptoms of hydrophobia made their appearance, and the

following morning he was visited by another medical man, who bled him from the arm to a moderate extent. The paroxysms increasing in frequency and violence during the day, in his struggles the bandage became loose, and he lost a very large quantity of blood. By this untoward event, and the exhaustion produced by his struggles to recover his breath, when nearly strangled by the spasmodic contractions of the muscles of the larynx, his strength was greatly reduced. His struggles during a paroxysm were said to be terrific, and it required the strength of four men to keep him down in bed.

Through the kindness of Mr. Brandon, jun., I saw this patient at eight o'clock, P.M., and remained at his bedside some hours. He was raving like a maniac, and was in a state of extreme debility. The face was pale, and the skin covered with a cold clammy perspiration; the pupils of the eyes completely dilated; the corners of the mouth retracted; the breathing hurried; the pulse 120 in a minute, thready and vermicular; and the paroxysms produced by the spasms of the throat terrible to behold. The head was on these occasions drawn backward, and he made the most vehement efforts to get out of bed, foam issuing from his mouth profusely.

Some chloroform had been administered during the afternoon. I recommended it to be repeated, and had the satisfaction of witnessing its effects, which were almost magical. He was no sooner under the influence of this potent spell than his respiration became perfectly tranquil; some colour returned to his cheeks; the pupils contracted; the pulse became calm, and, considering his weak state, well developed, the number of pulsations in a minute not exceeding 84; and he lay in a state of happy delirium. A more pleasing transition from extreme agony to tranquil ease I never witnessed before. The effect of the remedy was maintained during the night by the occasional use of small doses; but he died the following morning, without pain or agony.

It must be admitted that this was not a favourable case to test the power of chloroform as an antidote. The unhappy patient had lost so much blood as almost to induce me to believe that his death must be set to the account of phlebotomy, rather than to hydrophobia. But on the supposition that we are not yet in possession of a specific for this frightful malady, which is too probable, it must be a gratification to every humane mind to know that it is in our power to all-viate the dreadful sufferings peculiar to hydrophobia, and render the last hours of an unhappy patient tranquil, and free from pain.

In the case of hydrophobia related by Mr. Hunter, he says:—"The pulse in the beginning was not quick, nor was the skin hot; and there was none of the muscular debility so remarkable in fever;"* and Dr. Currie, of Liverpool, who saw five cases, says:—"In none was there any sense of animal heat."† It is clear,

* Transactions of the Society for Promoting Medical Knowledge. Vol. I., p. 308.

† Medical Reports. Vol. I., p. 179.

therefore, that the disease is not inflammatory, and blood-letting is contraindicated. There appears, indeed, to be an affinity between this disease and its congeners,—hysteria, mania, and tetanus, in none of which is there an increase of animal heat. Galen calls mania the “delirium sine febre;” and according to Dr. Beddoes “it is certain that tetanus exists without increased heat;”^{*} which conclusion is supported by the experiments of Dr. Currie, whose remarks on the impropriety of blood-letting in tetanus are equally applicable in hydrophobia.

“It is deeply to be lamented,” says this able pathologist, “that this disease should ever have been considered as of an inflammatory nature, and that there are even now physicians who treat it by venesection. It is in my mind decisive against this supposition that though the general system is so powerfully affected, the animal heat is not increased, which it uniformly is in all cases where there is an inflammatory affection of the system, whether originating or terminating in local phlegmonic inflammation.”[†]

Opium has always failed to give relief in hydrophobia; and I cannot think favourably of large doses of arsenic, as recommended by Dr. Billing. We may, however, hope that as we have obtained a remedy for the painful symptoms of this distressing malady, an *antidote* will yet be discovered. An eternal debt of gratitude is due to Dr. Simpson for his discovery of the anæsthetic properties of chloroform, which, if administered, with the cautions and restrictions laid down by Mr. Nunneley, of Leeds,[‡] can seldom be dangerous.

Beverly, June 29, 1852.

REMARKS

ON THE EFFECTS OF IODINE ON THE GLANDULAR SYSTEM, AND ON THE PROPERTIES OF KOUSSO.

By THOMAS H. SILVESTER, M.D., CLAPHAM.

Read at the Anniversary Meeting of the South-Eastern Branch.

ON THE EFFECTS OF IODINE ON THE GLANDULAR SYSTEM.

IN our journal the question has been asked,—Whether atrophy or absorption ever takes place in the glandular system from the use of iodine? In answer to this question, I would beg the favour of the present members of the Society to allow me to make a few remarks, the result of many years' attention to this point. From 1834 to 1844 a great many patients, suffering under secondary or tertiary syphilis, were admitted into St. Thomas's Hospital, more especially under the care of the late Dr. Williams, who had gained a high reputa-

tion in the treatment of these morbid symptoms. Most of these patients came under my notice and particular observation, and many of the remarkable cases were entered in my note-book, but not one instance of atrophy or absorption of the large glands, occurred in our experience. It was thought advisable, on the recommendation of Lugol, to test the efficacy of the iodide of potassium in scrofulous enlargement of the glands, and in order to give M. Lugol's method of treatment fair play, a most characteristic specimen of these affections was selected. A young woman, fat, florid, and fair, aged 18, was admitted with suppurating glands at the angle of the jaw, and others approaching suppuration or hard and inflamed, extending to the chin, were conspicuously prominent. Eight grains of the iodide of potassium, in camphor mixture, were prescribed, and steadily administered, for nearly six months, without the slightest perceptible effect upon the scrofulous mass of glands, and she was presented in much the same state as at her admission. Now, it happened that in this girl the breasts were largely developed, but no change was produced in their size by the treatment adopted for the scrofulous ailment, notwithstanding the full dose, and prolonged administration of the iodide.

There were at this period, before the treatment had become generally known, innumerable cases of syphilitic periostitis in which the iodide of potassium was very successful, and yet we never witnessed atrophy or absorption of either the breast or testicle during the use of this remedy. A case of simple hypertrophy of the breasts was then made the subject of experiment; eight grains of the drug were taken, steadily and continuously, for three months, but no diminution of the mamme took place.

A boy, aged 12, presented himself with immensely enlarged tonsils, and took the iodide nearly six months, without any impression having been made upon these organs. It would weary you to bring forward further illustration on this subject, and this negative kind of argument is, I am aware, not perfectly satisfactory, and may be destroyed by a single example of the positive power of the remedy in causing absorption of either the breast or testicle; but ten years' observation in a large hospital failed to furnish me with a single proof in favour of the opinion, that atrophy or absorption of the glandular system, in its normal condition, arises from the use of iodine in any form. Experience as to the topical application of this powerful agent, involves an inquiry into the effects of friction, stimulation, protection, and warmth, and excludes all inference as to its specific property. It must be confessed, that enlarged testicles not unfrequently yield to its influence, but it will be found on inquiry that in these cases the system has been contaminated by the syphilitic poison. The same remark is applicable to chronic induration of the inguinal glands. It is a very remarkable fact, that the swelling of the thyroid body, in common bronchocoele, vanishes under the internal use of iodine, especially the iodide of potassium. The rapidity and certainty of its removal are equalled only by that of the venereal node; and I have sometimes thought that there may be a vital

* Beddoes on Fever, p. 30.

† Medical Reports. Vol. II., p. 173.

‡ Transactions of the Provincial Medical and Surgical Association. Vol. XVI., p. 377.

elective attraction between the iodine and the lime, which latter forms the basis of the nodal tumour, and is, probably, the chief element in the thyroid enlargement.

It still remains to be explained, how it happens that tumours, enlargement and thickenings of a nature other than have been noticed, disappear under the use, topical or internal, of the remedy in question: the explanation is undoubtedly difficult; but I may be allowed to remark, that there is an absence of permanency in the glands generally, the thyroid disappears spontaneously, the tonsils naturally at puberty, the breasts in advanced age, and sometimes the testicles and ovaries; and there are few practitioners who have not met with cases of absorption of the breasts and testicles from some unknown cause, and in morbid instances when no medicine has been taken. I have over and over again known and seen large swellings vanish under the long-continued application of a poultice, or wet lint and oil silk; and an equal number of failures, where iodine, internally and externally, was had recourse to, have occurred to me.

I recommend this subject to my medical brethren, and I do not hesitate to say, that they will confer a great boon upon scientific medicine by determining, with certainty, the value and effect of iodine in the cure of disease.

ON THE PROPERTIES OF KOUSSO.

MUCH difference of opinion still exists with regard to the specific property of koussou or the *Brayera Anthelmintica*. It has been lauded by some as universally efficacious in the treatment of tape-worm, whilst by others it is described as inferior to either turpentine or the preparations of male fern. My attention has been drawn to this subject, more particularly of late, from learning that the price of the drug has undergone considerable diminution, and that we are likely to have a regular, abundant, and cheap supply from Abyssinia. My first patient gave *one guinea* for two doses of half an ounce each. The traveller, Mons. Rochet d'Hericourt, charged M. Simon, his agent in London, £1. 15s. per ounce. He had in his possession 1400 lbs., which, at even £1. 10s. per ounce would have produced him the enormous sum of 22,400 guineas. The ordinary price of the bruised flowers and leaflets, of which I have brought a specimen for your inspection, is two shillings the ounce. It is prudent to order the drug in this form, rather than as a powder, adulteration in the former case being more difficult of accomplishment.

I have not hesitated to prescribe the koussou, at its present reduced cost, even to my dispensary patients, and the cases about to be related, encourage me to hope that much benefit will be conferred upon the poor by its employment, (for it is they, chiefly, who suffer from the disorder,) and that ultimately it will be a recognised article of the *materia medica*. I now beg to read a case or two by way of illustration.

Case 1.—A girl, aged 15, came under my care at

the Clapham General Dispensary, for worms; she had been suffering from this cause nearly six years, and had undergone a variety of treatment, which had been partially efficacious in having brought away long portions of *tænia*; but the head could never be discovered in the evacuations. It often happened that after taking a strong purgative, she passed fifteen or twenty-feet of her internal enemy, and yet long pieces were evacuated every week or ten days. Her night dress frequently contained some of the articulations, and she was occasionally obliged to leave school for the purpose of having extruding portions removed.

Having taken large doses of the spirit of turpentine in gruel many times, and five grains of the sulphate of iron, with a drachm of salts, three times a day for several months, without avail, she discontinued her visits to the dispensary and placed herself under the care of my friend Mr. Angers, as a private patient. It was then determined to administer the koussou, and a dose was procured at considerable expense—namely, one guinea. It proved entirely efficacious; an immense mass of the worm came away, in which, after a most careful and minute examination, the head was discovered. This part might easily escape observation, owing to its minuteness; it appears singularly disproportionate to the size and length of the animal, not being much larger than a pin's head. It is characterised by four black points like eyes, but which are really suckers, by the aid of which this parasite worm absorbs the chyle contained in the intestinal canal. I preserved this part of the animal for many months in spirit of wine, but unfortunately my servant by mistake threw it away, to my very great annoyance. The first dose given to this patient answered the purpose, but it was thought advisable to repeat it, and accordingly another half ounce of the powder was infused in hot water, and taken the day after a gentle purge of castor oil. The whole of the worm seemed to have been removed, for the koussou, acted gently as before upon the bowels, but no articulations were found; the patient remained free from further inconvenience. This patient had been under the most eminent worm doctors in the metropolis, without benefit.

Case 2.—Miss T., aged 12, had suffered for three years from *tænia*, and taken turpentine, senna, calomel, and the usual drastic doses. The first dose of the koussou fully answered the purpose, for although the actual termination of the worm was not obtained, the mass was traced to a fine point, slightly jagged, and the patient has been free from the symptoms of the disorder a very long time. A second dose was given in this case also; it acted gently, as the first had done, but the motion contained nothing remarkable. The price had now been reduced to four shillings.

It would be easy to multiply evidence on this subject from the experience of my professional friends, but the two cases now brought forward are sufficient to prove that the *Brayera Anthelmintica* deserves a place in our *materia medica*, and a constant moderate price is the only circumstance wanting to bring it into general

use. It will be observed that its success did not depend upon the activity of its purgative quality. The action was gentle and far less severe than that of the ineffacious drastic remedies which had preceded it; we must therefore conclude that its operation is specific, and like all specifics, it will occasionally fail. There are many varieties of the tænia, and it is not improbable that to some of these it does not prove poisonous if its failure does not arise from adulteration. It seems to be a harmless thing, of no striking property in the human body when the worm is absent. I have given two drachms infused in hot water, to persons complaining of abdominal pains, who formerly suffered from tænia, and it has moved the bowels slightly and relieved the pains just as an ordinary dose of rhubarb would do, and with no other perceptible effect. It is now pretty generally known that the *Brayera Anthelmintica* was discovered by the traveller Bruce, it is classed amongst the *Boracæ*; and by De Candolle, in tribe v., *Dryadæ*. It grows in Abyssinia, to the height of twenty feet, and is cultivated everywhere for its anthelmintic properties. It is found in Tigre, Agame, and Shoa, and according to Dr. Beke, through the entire table land of North Eastern Abyssinia. The bunches are gathered before the seeds are quite ripe, whilst still a number of florets remain unchanged. Its peculiar property resides chiefly in its bitter acid resin, soluble in æther and in alcohol. The decoction strikes a dark green tint with a solution of the sesquichloride of iron. Dr. Pereira, from whose paper in the *Pharmaceutical Journal*, (Vol x., No. 1,) much information on the subject may be gained, gives the following directions for its administration:—"The powdered flowers are to be mixed with luke warm water, (for an adult, about ten ounces) they are allowed to infuse for a quarter of an hour, a little lemon-juice is then to be swallowed, and the infusion being stirred up, the whole is taken, liquid and powder, at two or three draughts, at short intervals, being washed down by cold water and lemon-juice. To promote the operation tea (without sugar or milk) may be taken. In three or four hours, if the remedy has not operated, a dose of castor oil or a saline purgative should be administered."—p. 24.

Not unfrequently, both in public and private practice, patients present themselves suffering from tape-worm; sometimes very little inconvenience is complained of, but generally there are distinct symptoms of the disorder. I am inclined to think that the popular notion is well grounded, and that, till the head of the animal comes away, the patient is not cured. There is seldom more than one worm, and yet portions are constantly being separated, which, if they possessed independent vitality, and the power of reproduction, would assuredly fix themselves on some other portion of the intestinal tube.

The Abyssinians feed upon raw meat, and to this rude practice may be referred the prevalence of this malady amongst these people. The *cysticercus* is found in the flesh of the pig and sheep in our own country, and if the tenia be a developed *cysticercus*, its origin here would be accounted for. Some very humorous, and yet instructive remarks on this subject are contained

in the last *Edinburgh Monthly Journal*. It is more than probable that the ova of the tenia, the ascaris, and some other parasitic animals, find their way into the human body through the unprepared or uncooked materials of our food. And it may be further remarked, that a low degree of vitality of the system greatly predisposes it to their attacks, and hence the value of steel and other tonics by way of prevention and restoration.

CASE OF SENILE GANGRENE.

TREATED BY LOCAL BLEEDING.

By JOHN COWLEY, Esq., WINSLOW.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—Should the annexed surgical case, which I consider embraces a deviation from the mode of treatment usually adopted by British practitioners, be considered worthy of your attention, and obtain an insertion in your valuable journal, my object will be accomplished.

I am Sir, yours very respectfully,

JOHN COWLEY.

Winslow, June 26, 1852.

On Monday, May 17th, 1852, I (being in the 74th year of my age) was attacked with an uneasy sensation in the second toe of my right foot, occasionally paining me like the sting of a nettle. Upon examination, the whole of the toe, to the first metatarsal joint, appeared of a red and inflamed colour, slightly tender to the touch, and somewhat enlarged. An application of diluted tincture of iodine produced no sensible effect. A second dressing of the same was applied on the 18th. On Thursday, the 20th, the whole toe was considerably enlarged, vesication had taken place all along its dorsum, and the colour of the toe was assuming a dark purple hue. The iodine was discontinued, and ceratum album with a spirituous lotion were substituted, with the use of Markwick's epithem, until Sunday, the 23rd, when the fourth and fifth toes became inflamed like unto the second, at its commencement, with a slight swelling without pain, but some irritation. From the fatal results I had witnessed of various cases during an apprenticeship and practice of fifty-nine years, and which cases had commenced in a similar manner to my own, I felt convinced (as no injury had been inflicted) that the disease was "senile mortification," and at once resolved to deviate from the long continued practice of trusting for a cure, to the use of cataplasms, opium, &c., (which rarely arrested the disease in its incipient stage, and seldom succeeded after sphacelus had taken place,) by trying the effect of local blood-letting. I therefore extracted eight ounces and two drachms of blood from the saphena minor vein immediately below the ankle-joint. The direct beneficial effect produced was truly surprising; the redness of the fourth and fifth toes was almost removed, and the dark shining appearance

of the second considerably improved in colour, and the swelling diminished. The same dressings were continued till Friday, the 28th, when a relapse took place, the fourth and fifth toes became inflamed to an equal extent with the third, the second toe was also increased in size and the colour darker; also the great toe showed decided signs that the disease was spreading to that part of the foot. I again took away eight ounces of blood, and this from the saphena major vein, situated over the middle of the first metatarsal bone. A similar result to the first bleeding was shown, the same mode of dressings was continued to the 2nd of June, when all the symptoms of the disease recurred, but not in so aggravated a degree. Five more ounces of blood were extracted from the same vein, three inches above the ankle-joint, with equally good effect, making a total loss of twenty ounces of blood from the foot in the space of ten days.

The inflamed parts were now dressed with Spt. Terebinthinæ, previous to the application of white cerate and epithem, but not agreeing, a common bread and water poultice was tried. However, not finding any material alteration, the Cataplasma Fermenti, P.L., was the next remedy on the 12th of June, which was continued for six days with advantage, when, although no ulceration existed the Ung. Resinæ was applied over the surface of the whole foot as a warm dressing, up to the present time; and now, I hope a permanent cure is effected.

During the first fortnight of the above period, the saline mixture, with the volatile alkali were freely taken, and since then Quin. Sulph., gr. v., bis die. Port wine and spirituous stimuli have been continued to this day, without increasing the number of pulsations beyond 66, and that only in the afternoon occasionally.

Although particularly enjoined by my medical friends to adopt positive and constant rest to my foot, I have persisted in the use of a leg rest and exercise in a garden chair; my general health being very good I considered fresh air and exercise essential to its maintenance.

Hospital Reports.

WEST NORFOLK AND LYNN HOSPITAL.

CASES ADMITTED UNDER THE CARE OF CHARLES COTTON,
M.D., F.R.C.S., SENIOR SURGEON TO THE HOSPITAL.*

Stone in the Bladder—Incontinence of Urine—Lithotomy a second time—Cure.

Charles Stanfield, villager, aged 15 years, admitted September 23rd, 1848. Has suffered from gravel and stone from infancy. Underwent lithotomy when three years and a half old at this hospital, when a calculus some grains exceeding two scruples in weight was extracted. The present symptoms have existed about three years. They are of the usual character, but of

late have become so distressing as to compel the patient to seek relief. An involuntary dribbling of urine has continued in a greater or less degree since he was last cut.

24th.—Passes urine guttatim. On sounding, the bladder was found empty, and the presence of two or more calculi detected. Haust. Tinct. Ferri Mur., m. x. Ex Aq. Cinamoni, oz. iss. ter die.

Oct. 4th.—The rectum freed by injection and the influence of cloroform induced. Lithotomy performed and three phosphatic calculi, weighing upwards of seven drachms removed. One, of a dumb-bell shape, broke during the extraction, showing an oxalate nucleus. The operation was conducted with much care, owing to the existing *stillicidium urinæ* indicating a contracted state of the bladder. An ample external incision was made at the seat of the former wound, and the staff entered low down. The perineum was found very deep, the distance to the bladder proving much greater than was supposed. In using the cutting gorget, the instrument was withdrawn once in order to limit the internal incision, which, when effected, would scarcely admit the point of the index finger, owing to the inelastic and unyielding condition of the prostate and neck of the bladder. A section of the opposite lobe of the prostate was then cutiously made by means of a probe-pointed bistoury, and the opening further dilated in that direction, by the forefinger and blunt gorget. The forceps and scoop served to complete the operation, which was somewhat further complicated by the violently-contracted state of the bladder.

October 5th.—Passed a good night; belly soft and free from tenderness; surface of the wound covered with calculous particles; napkins moderately wetted from the passage of the urine. The forefinger gently introduced through the wound to secure a free outlet; this was followed by a gush of urine. Ordered citrate of potash and diluents.

6th.—Going on well; urine escapes freely through the wound.

9th.—Much pain and smarting at the seat of the wound, which is smeared with chalky matter; relieved by hot water applications and pledgets dipped in almond oil, and anodyne draught.

12th.—Has passed water twice per urethram for the first time, some little yet escapes through the wound, which is considerably closed by granulation.

15th.—Passes water naturally but with considerable pain. Urine alkaline and purulent. Ordered Tinct. Ferri Sesquichloridi, m. x.; Syr. Papav., dr. ss.; ex aq. Cinnam., oz. iss. ter die.

18th.—Calculus impacted in the urethra removed after some trouble with the scoop end of a small director.

20th.—Phymosis, &c.; belladonna lotion applied; in other respects going on well.

27th.—Much pain from a small pisiform calculus detained in the urethra behind the scrotum; relieved by an anodyne and hot fomentations.

November 1st.—Quite well, excepting that he makes but a small quantity of urine at a time, and frequently wets the bed at night.—R. Liq. Potasæ, m. xx.; Tinct.

* Continued from page 422.

Hyoscy., m. x.; Decoct. Pareiræ Brav., oz. ij. Fiat haust. ter in die sum.

20th.—Ht. Pulv. Pip. Cubebæ, dr. j. ter die. Made out-patient.

January 1st, 1849.—Readmitted for a return of dribbling of urine on using any exertion. Catheter (No. 5) passed and retained in the bladder for different periods. Cold bath and varied administrations of belladonna, cantharides, nux vomica, and galvanism tried. Patient discharged able to retain his urine and void it in fair quantities. He now and then wets the bed, which is attributed by the nurse to indolence.

April 1st, 1850.—Readmitted for a return of incontinence of urine. A plugged silver catheter (No. 5) introduced and secured in the bladder. An elastic one afterwards substituted. The urine at first came away by the side of the instrument, but by the end of three weeks the patient, on withdrawing the plug, was enabled to pass seven or eight ounces at a time three or four times a day.

June 2nd.—Has had a catheter in the bladder for the most part up to this period, except when prevented by bladder irritation and feverishness. Instrument discontinued.

26th.—Passes six or eight ounces on each occasion of voiding his urine. Has wetted the bed two or three successive nights, but has not the least dribbling in the day. Catheter again introduced and retained. Ht. Pil. Strychniæ, gr. $\frac{1}{16}$ ter die.

July 4th.—Catheter withdrawn; cold douche every morning.

18th.—Passes about eight ounces of urine at a time; no incontinence since last report; urine pale and limpid, and of low specific gravity.

30th.—Discharged.

Stone in the Bladder—Lithotomy—Cure.

William Belton, agricultural labourer, aged 56 years, admitted February 10th, 1849, with symptoms resembling those of stone, for which he had been frequently under treatment during the last two years and a half. Catheter introduced and a moderate-sized calculus detected. Ordered full diet without beer, and a small dose of castor oil each morning to obviate habitual constipation.

February 20th.—The patient having been brought under the influence of chloroform. The ordinary lateral section of the perineum was made, and the staff entered low down; the subsequent incision through the prostate and neck of the bladder was then completed by means of the cutting gorget, and the wound further dilated with the forefinger and blunt gorget. The latter serving as a director for the forceps, with which a lithic acid calculus, weighing upwards of three drachms, was at once seized and extracted. The operation was unattended by hæmorrhage, speedily executed, and scarcely noticed by the patient. An elastic tube having been passed through the wound and secured within the bladder, the man was placed in bed with the knees flexed over a pillow. Anodyne draught and barley water.

Evening.—Going on well; urine escapes through the tube, high coloured, from admixture with blood; bladder injected with infusion of matico. To have a cooling mixture of nitre and mucilage.

21st.—During the night the patient was found in "*a delirious condition upon the floor, having suddenly fallen out of bed in a fit.*" Visited immediately by Mr. Cotton. Skin cool and clammy; pulse small and rapid; looks hazy and stupid, as if intoxicated; thinks he must have overbalanced on trying to raise himself in bed. There is some bleeding from the wound apparently caused by the forcible dislodgement of the elastic tube in falling. Ether draught administered and more sedulous watching enforced.

Evening.—Had a shivering fit at noon, but is now comfortable and composed. Pulse 88; skin moist; a great quantity of urine, now no longer tinged with blood, has escaped through the wound. Continue the mucilaginous mixture.

23rd.—Bowels unmoved since the operation. Enema of salt and gruel, with generous diet.

27th.—Urine for the first time passed partly by the natural passage, during the night. The nates are extensively ulcerated and excoriated; perineal wound sluggish and coated with mortar-like deposit. Constipation. Full diet, wine and porter. Nates protected by a free coating of collodion. Enema daily.

March 2nd.—The bowels act only after the use of the injection. There is much muco-purulent deposit at the bottom of the urinal. The ulcerated parts, however, are much improved and the wound is nearly healed. Collodion reapplied.—R. Magnes. Sulphat., dr. ss.; Tinct. Ferri. Muriat., m. x.; Tinct. Hyoscy., dr. ss.; Aq. Cinnam., oz. iss. Fiat haust. ter die sum.

4th.—Sitting up; urine becoming clear; bowels act daily; wound at seat of operation healed.—Pergat.

8th.—Medicine to be given less frequently, as he has been obliged to take some logwood decoction to check diarrhoea.

21st.—Discharged cured.

The above are the concluding cases of a series of ten commencing September, 1836, at the Lynn Dispensary, and ending February, 1849, in which the lateral operation was unattended with a single failure. To these are now to be added three consecutive cases since operated upon, in which death followed in every instance.

[To be continued.]

Proceedings of Societies.

SOUTH-EASTERN BRANCH.*

At the conclusion of Mr. Sankey's address, it was moved by Mr. BOTTOMLEY, seconded by Mr. HARGRAVES, and resolved unanimously,—“That the best thanks of this meeting be presented to the officers and

the other members of the Committee of Management, for their services rendered at and since the last meeting of this Branch of the Association."

It was then moved by Mr. STEDMAN, seconded by Mr. REID, and resolved unanimously,—“That Tunbridge Wells will be a convenient and appropriate place of meeting for the year 1853; that Mr. Hargraves be requested to accept the office of President of the Branch. Mr. Thompson, of Westerham, Vice-President, and that the following gentlemen:—Mr. Trustram, of Tunbridge Wells; Mr. Turner, of Tunbridge Wells; Dr. Duncan, of Tunbridge Wells; Mr. Baller, of Penshurst; Mr. Starling, of Hadlow; Mr. Wallis, of Hartfield, do constitute the Committee of Management.

Mr. Martin, of Reigate, having respectfully declined a re-election to the offices of Secretary and Treasurer, with the expression of his best thanks to his brother members for the kindness and indulgent consideration with which they had received his services, it was moved by Dr. GREENHILL, seconded by Mr. HARGRAVES, and unanimously resolved,—“That Mr. Peter Martin, of Reigate, be requested to accept the offices of Secretary and Treasurer of the Branch, and that the special thanks of the members present at this meeting be presented to Mr. Martin, the late Secretary and Treasurer, for the valuable services that he has rendered to the Association.”

It was then proposed by Dr. GREENHILL, seconded by Mr. REID, and unanimously carried,—“That, without wishing to find fault with the Editors of the *Journal*, and without expressing any positive opinion as to the merits of Dr. Cowan's plan, this meeting feels strongly that the conduct of the *Journal* requires improvement, and therefore begs earnestly to press this subject upon the attention of the general meeting at Oxford.”

Mr. JAMES REID, of Canterbury, exhibited some casts made of gutta percha, and remarked that this material afforded a ready means of easily obtaining a permanent record of the size and growth of tumours, and that, in some instances, it was superior to plaster of Paris, from the facility with which it was moulded, and the cleanliness of the proceeding. The casts demonstrated the increase of an aneurism of the arteria innominata during an interval of nine months.

Mr. Reid also presented to the meeting some specimens of calculi from the bladder,—namely, two large stones, which had been removed, after death, from the bladder of a middle-aged man, who had died in the Kent and Canterbury Hospital about fourteen years since, of malignant disease in the abdomen (mesentery)? Although he had been under observation in the hospital several weeks before his death, there had been no symptoms pointing to the existence of a calculus in the bladder. His history was imperfectly learnt. He had been known to have been an invalid from his youth, and for some time before his death he used to walk about the streets bending forwards, with a hand upon his abdomen. He was generally regarded as a “hypocrite,” perhaps from the want of marked evidence of disease about him. The larger of the calculi weighed fourteen ounces avoirdupois, the smaller eight ounces, seven drachms, their united weight being twenty-two ounces, seven drachms, avoirdupois. By the friction which had taken place between them, a curved surface, of considerable depth, had been worn in the smaller, which corresponded to a convexity on the larger stone. When placed together, the two calculi formed a connected outline, which represented a cone, the apex of which was formed by the small stone; their united size equalled the dimensions of a bladder, distended to about half its capacity. The point of interest in the case was, that so large a foreign body had existed so long in the bladder without producing, as far as was ascertained, any change from inflammatory action, or even occasioning symptoms indicating its presence.

A calculus, measuring two inches and a half in its

greatest length, and two inches and four-fifths in its largest circumference, and weighing two drachms, eighteen grains; it was rough, and of an irregularly ovoid form, being deeply grooved in one portion of its shorter circumference, and was composed of the phosphates. It was passed by a female, aged 50, who had been the mother of six children. When she was confined of her third child, twenty-four years since, the labour was very tedious, and protracted. Six weeks after this confinement, from some unexplained cause, she suddenly had retention of urine, for which she was not relieved for nearly sixty hours, when a very large quantity of urine was withdrawn; about a month afterwards retention again occurred, and was relieved by the use of the catheter. From this period there was incontinence of urine, which continued till December, 1850. The only period during which she passed water in any thing like a stream, was occasionally at night, but even then it more generally dribbled from her. In December, 1850, the urine began to flow in a stream, but with much pain, a sediment appearing in the water when allowed to settle. In May, 1851, she placed herself under Mr. Reid's care; she was then suffering from symptoms of inflammation of the bladder, the pain at times was intense, and there was a thick mucopurulent deposit in the urine, sometimes mixed with blood. The existence of a calculus was suspected, and after considerable persuasion had been used, an examination was permitted and attempted, but a difficulty occurred in finding the urethra, its usual situation being occupied by the traces of a cicatrix. The patient was extremely nervous and irritable, and would, on no account, allow the examination to be continued, nor would she subsequently give permission for another examination. For nine months she continued to suffer all the symptoms of inflamed bladder, and at times they were aggravated in a very severe degree. Leeches, blisters, opium, mineral acids, &c., afforded occasional relief. There was no incontinence of urine during this period, but retention occasionally occurred for a few hours, and was relieved by opium and the warm bath. At the end of this period she sent early one morning in great alarm, saying that, “after a night of severe pain, something had given way and come down.” On separating the thighs, the calculus exhibited was seen protruding from between the nymphæ, with its broad end still lodged in the soft parts; it was readily removed with the fingers. A free communication existed with the bladder, into which the end of the little finger could be introduced, and it was evident that the urethra had been in great part destroyed. No other calculus could be detected by a sound passed into the bladder. From this time all her symptoms ceased, and she recovered health and strength, but incontinence of urine has continued.

The remarks of Dr. Silvester, “On the Effects of Iodine and Koussou,” were then read. They will be found at page 446; after which,

Mr. WHITFIELD, of Ashford, remarked, that it having been found that the valuable anthelmintic koussou was liable to be preyed upon by minute insects, perhaps his mode of preserving and keeping for use, the secale cornutum, might be advantageously employed on behalf of the koussou.

On receiving the secale cornutum in a pulverised state, from a source he could entirely depend upon as to its efficacy, he poured a sufficient quantity of rectified spirit of wine to cover it, and by agitation it might be poured out the consistence of cream, a teaspoonful of which, added to a cup of boiling water, being allowed five minutes to cool, and then stirred, was sufficient for two doses.

Mr. Whitfield had adopted this plan for the last fifteen years, and the medicine loses nothing of its efficacy by being kept in this form any length of time.

Perhaps in the case of the koussou, as a larger quantity is given than of the secale cornutum at a dose, sherry might, with propriety, be substituted for the rectified spirit of wine.

The gentlemen present then adjourned to dinner, under the presidency of Mr. Sankey.

PETER MARTIN,

Secretary and Treasurer

SOUTH-WESTERN BRANCH.

THE SOUTH-WESTERN BRANCH OF THE ASSOCIATION held their annual meeting at the Devon and Exeter Hospital, Exeter, on Friday, the 13th instant. The following gentlemen were among those present:—P. C. De la Garde, (President,) Exeter; H. Appleton, Esq., St. Marychurch; W. Bradshaw, Esq., St. Marychurch; Wm. Card, Esq., Exeter; John J. Goodridge, Esq., Paington; W. Bowden, Esq., Totness; G. W. Lillies, Esq., Chudleigh; Robt. Kerswell, Esq., St. Germans; James M. Madden, R.N., Heavitree; G. Paterson, M.D., Edin., Tiverton; John Edwards, Esq., Bampton; R. Brent, M.D., Woodbury; C. H. Brooking, Esq., Brixham; W. D. Kingdon, M.D., Exeter; E. D. Walker, M.D., Teignmouth; William Kane, M.D., Exmouth; William Prater, Esq., Okehampton; Albert Baker, M.D., Staicross; E. P. Pridham, Esq., Exeter; George Evans, Esq., Seaton; P. Miller, M.D., Exeter; W. Kendall, Esq., Budleigh Salterton; Wm. Gabriel, Esq., Collumpton; R. F. Burrough, Esq., Dartmouth; Jon. Toogood, M.D., Taunton; J. H. James, Esq., Exeter; C. K. Webb, Esq., Exeter; R. L. Pennell, M.D., Cheriton Bishop; J. B. Bartlett, Esq., Teignmouth; M. Barry, M.D., Totness; C. B. Nankivill, M.D., Torquay; A. Kempe, Esq., Exeter; W. H. Cullen, M.D., Sidmouth; T. Shapter, M.D., Exeter; Wm. Clapp, Esq., Exeter; E. Empson, Esq., Crediton; W. Deans, Sandford; W. H. Elliott, M.D., Exeter; J. Edey, Esq., Exeter; F. Mackenzie, Esq., Tiverton; T. Crosse, Esq., Thorverton; Dr. Madden, Jacobstow; C. H. Roper, Esq., Exeter; R. Salter, Esq., Exeter; Augustus Drake, M.D., Exeter; S. Budd, M.D., Exeter, &c.

Mr. Swain, of Devonport, the President for the past year, was unable, from professional engagements, to be present, and the President-elect (P. C. DE LA GARDE, Esq.,) was at once voted to the chair.

Mr. DE LA GARDE commenced his observations by expressing his regret at the absence of Mr. Swain, who had conducted the proceedings last year at Plymouth, in a manner so creditable to himself, and so honourable to the Society. Being called upon to go over ground which had already been traversed so frequently, and by persons of so much ability, he felt that he had little now to add, and he must therefore deprecate criticism—expressing at the same time, a hope that, in the few remarks which he should make, he should give offence to no one; although they must of course expect, among so many gentleman, variety of opinion, which, indeed he rather wished to see, inasmuch as by discussion, and the expression and different opinions, new ideas were elicited, and good results were very frequently attained. He congratulated the meeting on the fact that their lot was cast in so beautiful a district—declaring that he did so, not from any merely sentimental feeling—observing that they all knew, as medical men, the extreme value of air and scenery, in the treatment of disease—and reminding them that their thanks were due, especially to Dr. Shapter, for the very remarkable manner and great industry with which he had brought that subject before them. Mr. De la Garde then adverted to the meteorological and geological

peculiarities of the district, and after a few observations on the success of the hospital practice in Exeter, concluded his oral address, and proceeded to read a paper which he publish *in extenso* :—

The question between ourselves and the Assurance Offices turns strongly in our favour. I told you some years since how I had returned the fees when offered, and refused to answer in respect of my own patients, any impertinent questions they might think proper to propound. I have found this exceedingly convenient—but as it involves a sacrifice, I do not urge you to follow my example.

Irregular practice gains ground. Its delusions are not confined to the vulgar and the ignorant. Rank, fashion, and enlarged education furnish forth its partisans. I am not surprised. I have long foreseen how the intellectual appetite would be surfeited. The wonders of reality pour in with such a flood that the marvels of impossibility are admitted with them. We are all crammed with all manner of instruction—as though the sole object of education were to teach men to sparkle in society. Very few are the cool and logical heads which can arrange and appropriate this boundless miscellany of propositions—true or false—thus presented to them.

Should we combat these idle fallacies? I think them best met by cold contempt. The educated man who believes that an ignorant servant, who cannot with both her eyes read “slut,” visibly written on a dusty table, can, by virtue of certain mysterious pawings, read a Greek chorus with her elbows—or that one drop, which produces no sensible effect, shall become a million of effective doses if divided into as many parts—is beyond the reach of argument. Besides, we place ourselves in the invidious position of assailants, and may inadvertently, substitute the austere spirit of martyrdom for simple silliness. I leave psychologists to determine the mental condition of such persons. Associate with them by all means, (I mean the patients, not the practitioners,) for many of them are refined and amiable—but do not reason with them.

But what should we do in the course of practice? We cannot confer with those who repudiate our principles, and act themselves on so-called principles which we deny. There is no common ground on which to stand. For the fee which we might receive, we can, under such circumstances, render no equivalent. It is therefore a plain duty not to meet such practitioners.

You will expect me to advert to our meeting of the 10th March on the subject of Medical Reform. I approach this vexed subject reluctantly, but, since our decision on its merit appears to have differed widely from that of the general meeting just held at Oxford, I deem it my duty to restate our proceedings—nor is my confidence in the wisdom of a large public meeting so implicit that I need refrain from assigning the collective argument, whence, as it seemed to me, our resolutions were derived. On certain points we wanted information, and therefore simply reserved our opinion—on others our disapproval was decided.

The whole character of this meeting, to consider the “Draft Bill, to produce uniformity of medical education and qualification, and for the registration of those licensed to practice in medicine,” was remarkable. All our district members had been invited, but the attendance was extremely limited—a most significant fact! We were indeed so few as not to inspire indignant eloquence, and the conversation (for it hardly assumed the formality of a debate) was chiefly conducted by experienced, but uninspiring men, who could be vigilant and earnest, without being cross or enthusiastic. They evidently thought that, as legislation would neither increase any medical man's income, nor improve his social position, we might control our feelings, and bear with each other while we discussed the clauses of this

draft. So was it not when a mere difference in the expression of the same opinion was held to justify the alienation of old friends. No prudent or thoughtful man would then put his hand to the work. Such intemperance has postponed the correction of acknowledged defects, and subjected our cause to contempt and ridicule.

The first two clauses required no comment. It was otherwise with the third, "the appointment of the medical council for England," which ran thus:—

"III. *Appointment of the Medical Council for England.*—That a Council shall be established, which shall be styled—'The Medical Council for England;' and that the Regius Professor of Medicine in the University of Oxford, the Regius Professor of Physic in the University of Cambridge, and such one of the Medical Professors in the University of London as shall be from time to time designated by the Senate of the last-named University, shall be members of the said Council in right of their several Professorships; and that the other members of the said Council shall be six persons, to be chosen by the Royal College of Physicians of England, (not more than three of such six persons being fellows of the said College,) six persons to be chosen by the Royal College of Surgeons of England, (not more than three of such six persons being fellows of the said College,) and six persons to be chosen by the Society of the Art and Mystery of Apothecaries of the City of London, (not more than three of such six persons being members of the governing body of the Society;) each of the said appointments to be made within one month after the passing of this Act; and the powers and duties, vested in the said Council by this Act, may be exercised and executed by any six members thereof."

This clause, loose and indefinite, affected an exactness and precision which claimed, on behalf of the Committee by whom it was drawn, a thorough knowledge of the duties to be performed by the Council, and, possibly, of the very men whom they deemed best qualified to perform them. The new Charters for the great medical corporations might also have been contemplated. But, as we were wholly uninformed on these matters, and as the Council were to possess uncontrolled powers, as well as a vast patronage in dispensing the income which we were to be required to contribute; and as we could not learn by whom, or in what manner, the majority of its members were to be chosen, we resolved unanimously:—

"That, in the absence of sufficient information, this meeting desires to suspend its opinion relative to clauses 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12."

We afterwards resolved, and I may here state that all the resolutions were carried unanimously:—

"That, in regard to clauses 17, 18, and 19, the following be introduced, viz.:—That certain trustees be elected from the general body of the profession, in whom shall be vested the power of disposing of all surplus monies, whether derived from fees arising from registration, examination, or from penalties; and that such trustees shall not be members of the Council, or of the Examining Board."

However difficult Medical Reform may have proved, yet it is most strange that registration—at once fair, simple, and complete—should have encountered opposition. The quack has reaped the benefit—the profession and the public have endured the wrong, and borne the loss. The penalty proposed by the Bill was probably sufficient, and afforded as large a protection as the spirit of the age would tolerate. It was therefore resolved:—

"That this meeting entirely approves of the clauses referring to registration and penalties."

The fifteenth clause read as follows:—

"XV. *Candidates for Licences to produce Testimonials to the Medical Council.*—That every person who may present himself before any of the said Medical Councils for the purpose of obtaining a licence to practise medicine, shall produce proofs to the said Council that he has attained the age of twenty-one years, and shall also produce such testimonials as shall be satisfactory to the said Council, that he has applied himself to the study of medical and surgical science during a period of four years, and that during the aforesaid period he has passed at least three years in some University or medical school, approved of by the said Council; and that he has attended such courses of dissection, such clinical and other lectures, and such hospital practice, and has passed such several examinations before the Examining Board appointed by the said Council, as the said Council shall from time to time appoint."

Our meeting considered that by this clause all instruction, save in the Metropolis, or in regularly constituted schools elsewhere, (which must always be few, and will never remunerate their teachers,) was virtually ignored; and they thought it strange that a committee, professedly provincial, should treat provincial practitioners with such utter contempt. They foresaw that this Bill, should it become law, would suppress the private practitioner as a professional instructor. His capabilities of teaching were evidently regarded as too despicable even to be contemplated. Our members thought otherwise. They thought, and I thought with them, that the three or four years tutelage of a general practitioner, is, if properly used, the most valuable part of a general practitioner's education. It trains a youth to habits of business, it teaches him to regard his profession as a practical art, instead of a mere interesting branch of natural philosophy. It requires of him that whatever knowledge he possesses should be diligently applied, or, if he does not so apply it, forces upon him the conviction that he is deemed an idler or a coxcomb. I will assume an extreme case to prove that there is no provincial instruction so mean but that a pupil might—and would if it were required of him—learn enough to enable him from the first to comprehend his instructors in the London schools. I will suppose a youth apprenticed in a small town to an over-worked master—the medical officer of a sick-club or a parish. In the course of three or four years he might acquire considerable knowledge of materia medica, therapeutics, and pharmacy. He might acquire the elements at least of chemistry. He might make himself a good osteologist. He must have seen a little surgery, and probably a good deal of the practice of medicine—a most important consideration, for Hospital practice in London, except in the case of dressers or clinical clerks, or students who have already seen much practice, is of little worth. Now, if instead of neglecting his master's service and getting into mischief—to which his unemployed leisure tempts him—he had occupied these three or four years in such studies which he would do if he knew that a matriculation examination awaited him, and which he will not do while matters remain as they are—he would enter the schools so prepared to understand what he there might see and hear, as to return after two winters and one summer, an infinitely more trustworthy practitioner than he will after three years as now proposed.

The following resolution, which embodies more plain good sense on medical education than I have found in a century of wearisome lucubrations on that contested subject, we owe to two old and experienced practitioners—men by no means adverse to reform, but not inclined to run after every Will o' the Wisp that bears its name:—

"That the following alterations and additions be recommended in clause 15:—That 'for a period of four years' be substituted 'for a period of not less

than five years'; and that the following regulation be added—viz., that no pupil be admitted to an University or other regular School of Medicine to hear lectures unless he shall have previously undergone a matriculation examination to prove that he possesses sufficient elementary professional knowledge to enable him to profit by the course of study established in such School or University; and this meeting strongly urges, this suggestion upon the attention of the Central Council, as it would render highly profitable a period of time too frequently turned to little account in the acquirement of knowledge, practical and theoretical, and would also prevent the necessity of such expenditure of time and money at the metropolitan schools as is contemplated by the present clause."

That no preliminary examination should have been instituted either at the College or the Hall, but that young men (who are nevertheless assumed by these learned bodies to be utterly ignorant) should be required to attend four or five lectures a day—lectures most painfully elaborated by eminent philosophers, each devoting his utmost energies to his single subject, and, in the competition of the schools, eager to excel his rivals in the depth and refinement of his teaching—is inexplicable, unless these great corporations, whilst gratifying their half-laudable ambition, wholly lose sight of the capacity of the youth they have undertaken to instruct.

In short, although not the subject of any special resolution, the whole draft would appear to have been regarded by our meeting as the puniest of the offspring to which the Medical Reform movement had given birth. It stopped just where the necessity for legislation begins. It opened the common portal, and left us to grope in the dark. Up to an equivalent for the Apothecaries' licence (of which it timidly copied each prejudice—venturing only to abandon that one portion which implies some small confidence in us rustics) all was clear enough. Henceforth all was murky or void. To be sure there was the charitable fund—involved in portentous obscurity; and the registration clauses and their penalties—excellent it was admitted: the latter borrowed without acknowledgment from Sir James Graham's repudiated Bill. But his Bill, insolent and unjust though it were, did really contain the elements of practical reform. It defined, boldly and clearly, though with an injurious nomenclature, the various grades of the profession; and provided that title and position should bear their due relation to education and acquirement. It forbade that any man should go forth with the highest title, because he had not afforded the time, the labour, or the cost, required for the lowest; nor would it tolerate that any two practitioners should obtain the same degree, the one after the very highest, the other after the very lowest possible course of instruction. It annihilated cheap schools and shabby honors. Perhaps the Committee feared to follow it in such high matters, and so their Draft Bill turned out neither deferential, nor original, nor rash, but simply contemptible.

It was indeed conjectured that this might be intended only as the first instalment of medical reform. If it were so, ask yourselves how often the Legislature is likely to endure the occupation of its time by our ill-digested schemes. Would you ascertain how light is the weight of our influence, political or personal? Let me point your attention, however distasteful it may be, to the Union board-room, and all the indignities heaped there on our professional brethren. If personal character, if the sympathy of guardians who are neighbours, and, it may be, friends and patients, cannot defend from these wrongs, what, suppose you, will the nation care for the conflicting opinions of the ten thousand individuals, scattered as they are throughout the land, who make up that ill-compacted entity—the medical profession?

There are indeed some few members of that profession, who, trained in public schools and Universities, are regarded by the class whence our legislators are supplied, as personal friends. Yet, unhappily, against these men, whose position in society raises them above the base and wicked spirit of hostile rivalry, no pains have been spared to stir up our jealousy, and to isolate the great body of practitioners from those who alone could obtain a hearing or would dare to ask it.

Should this Draft-Bill die a natural death, as I suppose it will, I trust the profession at large will take up sounder and wider views of Medical Reform. I hope they will insist on a very different course of instruction from the over-be-lectured system of the College and the Hall; that they will require, previous to examination, some sort of experience—less ambitious, but more instructive—than that obtained by the dense mob of youths—students they are called—who trot round the wards of the Metropolitan Hospitals at the heels of some distinguished teacher, and pay for their exercise as "medical practice;" and that they demand on behalf of the candidates that they be examined by printed papers, and give their answers in writing, and be no longer subjected, as is commonly reported, and I fear in some few instances with truth, to the pettishness or rudeness of *viva voce* examinations; and lastly, and above all, that the title borne should be some guarantee to the public of the value of the man who bears it.

But neither the Committee who drew up this Bill, nor the great medical corporations, but reformers themselves are those whom in this matter I would chiefly blame. It has happened that very ordinary persons have taken credit for accomplishments, which they did not themselves possess, but noisily demanding them from others—"enlarge the curriculum, elevate the standard, increase the difficulty, and raise our profession in the scale of society"—such has been their cry. Be not deceived. The world is a shrewd world, and knows well—for the knowledge has unhappily been forced upon it—that natural science does not necessarily form the character of a gentleman. It knows—for it has been made to feel—that vulgarity of manners, coarseness of language, and laxity of morals, may consist with high professional eminence. It is a shrewd world which hates pretence, and despises pedantry, and cares not a rush, and will not pay us for any merely curious philosophy, but only as it has direct reference to our ability in treating sickness. It discriminates our various circumstances, and metes out its licence to each individual with practised sagacity—for the world is mighty practical. The physician of prolonged education and varied attainments, who ponders comfortably in a well-hung chariot, who makes a fine income, and has leisure still, may cultivate his botany with none to blame—in him it is science. But conceive the blank astonishment of the burly yeoman who should detect his own doctor presuming to waste an hour on picking weeds—in him it were nonsense or idleness, or worse.

But, if these scientific superfluities will not raise us in the social scale, I can tell you what will lower us; to speak ungenerously of our professional neighbour—to carp at his practice—to sneer at his knowledge—to aggravate his errors—to calumniate his character—to underbid him in competition—to retain practice, which annoys ourselves, lest a younger, or less fortunate man might succeed to it—and to keep possession, if we can, of any chance patient whom his illness, or his absence, might have cast upon our hands.

Mr. JAMES moved a vote of thanks to the President, for his excellent address, expressing his conviction that the meeting would agree with him, that it deserved more than a common meed of praise.

Mr. PRIDHAM briefly seconded the resolution, which was carried by acclamation.

Mr. PRIDHAM then, in an address of some length, commented upon the proposed Medical Reform Bill,

adopting and enforcing the view which had been taken of that measure in the President's address. He showed, by copious extracts from the *Journal*, that the authors of the measure were by no means justified in saying, that it had been "enthusiastically" or even unanimously, welcomed by the profession. He contended that it was characterised by a complete disregard of the opinions, the interests, and the feelings of the provincial practitioner; dwelt especially upon the defective nature of its provisions for preliminary training; condemned, as injurious to the public as well as the profession, the proposal to ignore the period of apprenticeship, and so to deprive the youthful student of the great advantage which such apprenticeship conferred upon him; and concluded by proposing the appointment of a small Committee, to confer with the Committee on the Bill, with the view of ascertaining what their intentions were, and what modification it might be possible to make in its provisions.

Mr. JAMES seconded the resolution which had been proposed by Mr. Pridham, believing that the course which he suggested was the best that he could take. He might be asked why, if he objected to the Bill, he had not stated his objections at the general meeting at Oxford, where he attended, with several gentlemen whom he had the pleasure of seeing now present? His answer was, that he saw that the feeling at that meeting was so strong, that it was no use to object; and he had also stated his objections previously. When applied to by Sir Charles Hastings, in the spring, to attend a deputation which was intended to wait on Sir George Grey, on the subject of the Bill, he had informed him that, willing as he should be to support him on all occasions in which he could concur, he could not concur with him in reference to this Bill. He had pointed out to him the evil which he thought would arise from calling again into existence the old apothecary, and he was sure that, unless it were much altered, that would be its inevitable effect. He believed that, by replacing the old apothecary, the Bill would do great damage to the profession and to the community. The Bill it was true contained penalties, quite sufficient, if they were enforced, to guard against druggists practising as apothecaries, but how were these penalties to be made available for that purpose? Was he to become an informer against the druggist so practising? Was there any gentleman in that room who would consent to do it? He was sure there was not. There was, however, a way in which the machinery provided by this Bill might be turned to account for this purpose, provided its provisions were altered. The Bill proposed that there should be a Registrar, and that an annual fee should be paid by every member of the profession. But how was the money, when contributed, to be disposed of? Nobody knew how, or by whom, or for what purposes. Now it seemed to him that if, in addition to the Registrar, sub-Registrars were appointed, in all parts of the country, who should be paid officers, and whose duty it should be to inquire into all cases of irregular practice, within their particular districts, and to take the necessary steps for their repression, it would be the means of giving an essential protection to the profession. He agreed with those who thought that the Bill, in its present shape, would bring the profession, throughout the country, more and more under the government of the metropolitan practitioners. He had the highest respect for those gentlemen, and believed that they were animated now by a more liberal spirit than they had ever been before, but he thought that it was due to the provincial practitioners that they should by fully and effectively represented in any Council by which the whole body of the profession was to be governed. Now what did this Bill propose to do? It provided for a Council to consist of certain *ex officio* members, and of six members of the College of Physicians, six members of the College of Surgeons, and six members

to be appointed by the Secretary of State. But what was to be the remuneration? Three guineas a day. And he would ask whether there was any practitioner in Devonshire, or in the north of England, or in any district at a distance from the metropolis, who would, or could, go up to London, to attend the meetings of the Council, for three guineas a day? (Hear, hear.) Therefore, he repeated, the practical effect of this measure would be, to concentrate in London, and the immediate neighbourhood, the whole government of the profession. He had never omitted any opportunity of insisting, that, as a matter of right, and of necessity, the provinces should have a fair share in the representation, as well as the metropolis. He had done it in this city when he had the honour to be President; he had done it in Liverpool; and he had done it in London two years ago, at the annual dinner of the College, when he was called on to respond to the toast of "The Provincial Surgeons." He felt that it was, at this moment, more than ever important that these views should be pressed, and he knew of no better way than that which Mr. Pridham had suggested, of appointing a Committee to confer with those to whose hands the matter had been entrusted by the general meeting of the Association.

The resolution was unanimously passed, and Mr. Pridham having suggested that the Committee should consist of two physicians, two surgeons, and two members of the Apothecaries' Company, the following gentlemen were named:—Dr. Pennell, Dr. Shapter, Mr. Barnes, Mr. James, Mr. De la Garde, Mr. Pridham. Dr. Shapter was requested to accept the office of Chairman.

Proposed by Mr. KERSWILL, seconded by Mr. BURROUGH, and carried unanimously,—“That the next annual meeting be held at Torquay.”

Proposed by Mr. PRIDHAM, seconded by Mr. APPLETON, and carried unanimously,—“That Baruch Toogood, Esq., of Torquay, be the President-Elect.”

Proposed by Mr. MADDEN, and seconded by Mr. BURROUGH, and carried unanimously,—“That Dr. Kingdon be requested to continue his invaluable services as Secretary.”

Proposed by Dr. KANE, and seconded by Mr. GOODRIDGE, and carried unanimously,—“That Mr. Fuge, Dr. Tetley, Dr. Black, Mr. Square, and Mr. Hunter, be the new members of the Council, in the room of Mr. Toogood, Mr. Elliott, Mr. Gillard, Mr. Puddicombe, and Mr. John Elliott, who retire according to Rule 17.”

In the course of the discussion, Mr. PRIDHAM paid a graceful tribute to the eminent ability and high character of Dr. Blackall, which was warmly seconded by the President, and cordially received by the meeting.

About forty gentlemen sat down to dinner at Pratt's London Inn; and the evening terminated with a most agreeable *conversazione* at Dr. Shapters.

EPIDEMIOLOGICAL SOCIETY.

At the last ordinary meeting of this Society, held at the House of the Royal Medical and Chirurgical Society, on Monday the 2nd ult., a paper "On the Influence of Hill Climate in India on European Regiments," transmitted from India by Surgeon Superintending Corbyn, and communicated by Lieut. Colonel Sykes, V.P.R.S., was read by Dr. Mc William, Hon. Sec.

The objects of this interesting paper, which was illustrated by statistical and meteorological tables, was to show that in India the elevated regions do not possess those superior advantages in point of health over the plains, which are generally ascribed to them; and that

the mortality among European regiments frequently increases in consequence of a removal from the plains to these "Hills Sanatoria."

The length of time occupied in the reading of the paper precluded all possibility of its being discussed by the meeting, which was the more to be regretted as there were some gentlemen present who had served in the high, as well as in the low lands of India, whose opinions regarding the peculiar views contained in this paper it would have been important to ascertain. The Society will resume its meetings on the first Monday in November.

Correspondence.

ON THE CASE OF DOUBLE AMPUTATION REPORTED BY "NIL DESPERANDUM."

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In answer to Mr. Lawrence's communication, inquiring why chloroform was not administered in the case of double amputation I reported in your *Journal*, I have to state that the question was considered by the surgeons of the infirmary in consultation, but from their not being decided on the point, whether chloroform does not add to the collapse in cases of injury that require amputation, it was not given. A man who underwent double amputation lately in the Bristol Infirmary took chloroform, but he did not recover. The case is as follows:—An engine driver, a young man, was admitted August 3rd, 1852, under Mr. Green, at four o'clock, P.M. He quitted his engine to shift the points, but on attempting to ascend he missed his footing and fell on the rails, the engine passing over both legs. The right limb was crushed and lacerated from the upper-third of the thigh, to within a short distance of the ankle-joint. The injury of the left limb was confined to the lower-third of the leg, involving the ankle-joint and splintering the tibia; the foot was only attached to the leg by the soft parts posteriorly. He was much depressed on admission; brandy to be given frequently. At half-past seven, P.M., re-action was fully established, his pulse was good, the skin was warm, and he had become impatient of pain. It was considered that he was able to bear the operation. Chloroform was inhaled, and Mr. Green removed the right thigh at the upper-third by the circular method. Before the operation was completed, the pulse became very weak. Mr. Green ordered that the chloroform should be discontinued, it being his opinion that in cases of extreme collapse, it has an unfavourable influence. Brandy was then freely given, and ammonia inhaled, by which means his powers revived. Mr. Green then removed the left leg at the upper-third by the circular method. During this time he was unconscious, but restless, the pulse sinking to a very low ebb, unless brandy was almost constantly being given. At the completion of the operation he was greatly collapsed and insensible. He did not speak from this time up to his death, which occurred at six o'clock, A.M., the following morning. It is, of course, difficult to say what amount of collapse is due to the operation, and what to the chloroform; it is a point that can only be determined by the careful

observation and comparison of a great number of cases in which the agent is, and is not given. The impression left on the minds of two of the surgeons who were present at the operation I have related was,—that chloroform was prejudicial, and which was strengthened on comparing it with that of Faulkner, who was more depressed, and who underwent a more severe operation—viz., that of both thighs. I know that this opinion is contrary to that most generally held; but either the one or the other opinion can only be supported by the result of cases.

I see in Mr. Cole's work "On Military Surgery in the Punjab," (lately published) that he speaks most decidedly against the employment of chloroform in amputations for injuries. It would be interesting to know from Mr. Lawrence the particulars of his cases.

I remain, Sir, yours very truly,

"NIL DESPERANDUM."

Bristol, August 11, 1852.

THE PRESIDENCY.

To the Members of the Provincial Medical and Surgical Association.

GENTLEMEN,—I beg most respectfully to call your attention to various points in the management of the Association which seem to demand a reform.

I will mention only one in the present number of the *Journal*; it is, the great disproportion in the relative number of the Presidents chosen from Physicians and Surgeons.

I give the names of all the Presidents from the formation of the Association, with their respective years of office. You will find the printed list from which it is derived (except the four last Presidents) at page 401, of the 17th Volume of our "Transactions."

<i>Physicians.</i>		<i>Surgeons.</i>	
Dr. Johnstone ...	1832-3	Mr. James ...	1842-3
Dr. Carrick ...	1853-4	Mr. Hay ...	1843-4
Dr. Johnstone ...	1834-5	Dr. Crosse ...	1846-7
Dr. Kidd ...	1835-6	Mr. Norman ...	1848-9
Dr. Holme ...	1836-7		
Dr. Boisragon ...	1837-8		
Dr. Barlow ...	1838-9		
Dr. Jeffreys ...	1839-40		
Dr. Steed ...	1840-1		
Dr. Goldie ...	1841-2		
Dr. Robertson ...	1844-5		
Dr. Favell ...	1845-6		
Dr. Heygate ...	1847-8		
Dr. Hastings ...	1849-50		
Dr. Horner ...	1850-1		
Dr. Jenks ...	1851-2		
Dr. Ogle ...	1852-3		
Dr. Bird ...	1853-4		
Total number of Physicians	18
Didto Surgeons	4

22

I have included Dr. Crosse among the surgeons, because he was known chiefly as a surgeon.

For the first ten years no surgeon was elected President. If Dr. Crosse were added to the physicians, then rather more than seven physicians have been chosen to one surgeon.

I need not ask whether this is fair. I do ask, however, all the members of the Association, and the physicians especially, to take this very important question into their immediate consideration, with a view to its correction by an alteration of the sixth law, if necessary.

I shall be glad to receive any suggestions.

SAMUEL CROMPTON.

3, Cavendish Place, Manchester,
August 25, 1852.

[The sixth law leaves the matter at the option of the anniversary meeting, who have always elected the gentleman fixed upon by the Local Council.—Ed. J.]

TREATMENT OF A POOR-LAW MEDICAL OFFICER.

To the Editors of the Provincial Medical and Surgical Journal.

SIR,—Will you oblige me by inserting the following statement in the next number of your journal, in order that the medical profession and the public may be informed in what manner a Board of Guardians in the west of England can treat a Poor-Law Medical Officer?

I am, Sir,

Your obedient Servant,

JOHN CROUCH, M.R.C.S., M.S.A.

Bruton, Somerset, August 14, 1852.

On the 29th of December, 1851, an order, signed by the relieving officer, was left at my residence, requesting my attendance on Mary White, a pauper, of Evercreech, nearly four miles distant, who was stated to be in labour. As a previous professional engagement prevented my attending, I requested my qualified assistant to go without delay. He went, and arrived at the patient's house before the messenger had returned home. His presence was little required, as the labour had scarcely commenced, the mouth of the womb not being larger than a sixpence. It was the extremely weak and half-starved appearance of the pauper that induced him to remain in attendance. At two o'clock, P.M., flooding first took place, and upon a further examination it was ascertained that there was an after-birth presentation. The pains having ceased, my assistant immediately gave the ergot of rye, plugged the vagina to restrain the hæmorrhage, and sent a man on horseback to me, requesting a consultation. The messenger came through Bruton to me, at Castle, the distance of seven miles, where I had gone to assist a neighbouring practitioner in the amputation of an arm. As the operation was urgently required, I was unable to leave, but directed that a carriage should be hired, as quickly as possible, and that my able and experienced friend Mr. Stockwell, should be requested to go to Mary White. Mr. Stockwell arrived at Evercreech between four and five o'clock. He found the patient in a very low condition, but the hæmorrhage had ceased. He remained nearly three quarters of an hour in consultation with my assistant. The flooding did not return during his visit. It was agreed that the patient should be constantly supplied with stimulants and nourishment, and if the

flooding should return, my assistant was to turn the child and deliver the woman. I proceeded to Evercreech between five and six o'clock, and met Mr. Stockwell on the road. We consulted on the case, which he considered a most dangerous one, and that the patient, when he saw her, was too weak to undergo the operation of turning, but if the flooding returned, he advised me to deliver the woman as a last resource. When I arrived the hæmorrhage had just begun to return, and it was clear that if the operation of turning were not performed, the woman would die undelivered. As there had been no labour pains since the flooding had commenced, the mouth of the womb was not so large as half a crown, and it required no little trouble and difficulty gradually to dilate the opening and introduce my hand. After kneeling from twenty minutes to half an hour on the stone floor of a dirty cottage, the child and after-birth were brought away in the usual manner. The woman did not survive the operation more than three quarters of an hour. It is right to state here, that the patient, before her confinement, was so weak in body and depressed in spirits, from consumption and other causes of a mental nature, that in all probability she would scarcely have survived natural labour. Her doom was sealed as soon as the flooding commenced, and no skill could have saved her life.

The following week my account was forwarded, as usual, to the Board of Guardians, containing a charge of two pounds for the case, including the nine hours' attendance of my qualified assistant, Mr. Stockwell's journey and consultation, and the performance of a difficult obstetric operation by myself.

This enlightened Board of Guardians refused to allow the above fee, and with their accustomed generosity offered me the sum of ten shillings! I appealed to the Poor-Law Board, who, after communicating with the Shepton Mallet Board of Guardians, received from the latter the following truthful and intelligent letter:—

Shepton Mallet, 11th February, 1852.

MY LORDS AND GENTLEMEN,—I am directed to acknowledge the receipt of your letter, No. 3006, dated the 27th ult., containing a copy of a letter addressed to you by Mr. Crouch, Medical Officer, with reference to a disallowance in (sic) his charge for attending Mary White in her confinement. I am instructed to state, that the Board of Guardians, on receipt of the letter referred to, gave directions to their Relieving Officer, Mr. Bown, to make inquiries relative to the case, and report thereon. The following facts were stated by him to the Board at their meeting of the 10th instant:—

“Mr. Crouch was from home when the order for attendance on the woman (which was obtained at nine o'clock in the morning,) was left at his residence, that his assistant attended the case, but that he could do nothing to relieve the patient, she was, therefore, obliged to remain without medical assistance until Mr. Crouch returned home, which was not till seven o'clock in the evening, when the operation described in Mr. Crouch's letter, took place, but without any beneficial result, the poor woman having died shortly after. I am to state, that the Guardians are of opinion, that had the patient had the assistance of Mr. Crouch at an earlier period, her life might have been spared. I am instructed to add that, as a general rule, the Guardians

consider 10s. sufficient for midwifery fees, and they are of opinion that in this case Mr. Crouch is not entitled to a higher fee."

I have the honour, &c.

(Signed) for G. M. MACKAY.

J. THOMAS.

In reply to the above libellous production, I informed the Poor-Law Board, that not only were its contents manifestly *untrue*, but that they were contrary to what was stated to the Guardians by their own Relieving Officer, Mr. Bown.

The Board of Guardians still refused to pay more than ten shillings, although the Poor-Law Board *twice* recommended them to reconsider their decision, and although the meaning of the order is so clear that "he who runs may read." The order is as follows:—"Provided that in any special case in which great difficulty may have occurred in the delivery, any district medical officer *shall* receive the sum of two pounds."

The Poor-Law Board having intimated "that it was open to me to take proceedings in the County Court against the Guardians of the Shepton Mallet Union, for the recovery of a fee for my attendance on Mary White," on the 31st of July last, the Chairman, Vice-Chairman, and Clerk of the Union, were summoned to the County Court at Wells.

After Mr. Stockwell and myself had given evidence that the case of Mary White was a rare and difficult one, an abortive attempt was made by the defendants to prove that there was a want of skill on the part of my assistant, great neglect on my side, and also that it was not a difficult case. Their witnesses consisted of a medical man, who knew nothing of the nature of the case before he entered the Court, and of an old woman, who was not even a village midwife, and had never confined a person in her life. Both of these gave evidence distinctly in my favour.

The Judge of the Court, who exhibited on the occasion his usual acumen, concluded the case by saying,—"There is no defence whatever to this action. The plaintiff must have his two pounds; and it would have been more creditable to the Board of Guardians if they had consulted Mr. Stockwell about the nature of the case, instead of sending for an ignorant old woman, who scarcely knew her right hand from her left, and whose only clear idea is, that she has had a large family without much difficulty or trouble."

P.S. The above facts speak for themselves, and require on my part no further comment.

MR. TOYNBEE'S NEW AURAL APPARATUS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—If Mr. Yearsley had attended the late meeting at Oxford, he would, doubtless, have been quite at liberty to have stated any objection he might entertain to the instrument proposed by Mr. Toynbee for relieving perforation of the membrana tympani, provided that he avoided any personal discourtesy in his remarks. In making such objections in his letter, published in the last number of the *Journal*, it was

surely unnecessary to say anything that might be construed into an insinuation of improper motives on the part of Mr. Toynbee, so little, if anything, having been done to justify such innuendoes.

The hackneyed proverb, that "those who have glass windows should not throw stones," still retains its force; and the profession generally, I think, will scarcely acquit Mr. Yearsley of the very fault which he seems to insinuate against Mr. Toynbee. Very few indeed will be of opinion that the mode of obtaining notoriety adopted by Mr. Toynbee on the occasion alluded to, was otherwise than perfectly legitimate, which I think is more than can be said of a little book of Mr. Yearsley's entitled "Deafness" &c., which I have met with in the hands of some of my patients. It is unnecessary here to allude to other instances of the kind, and had Mr. Yearsley abstained from writing in a manner savouring too much of professional jealousy, no one, I presume, would have complained of his preferring his own bantling to that of his neighbour. In conclusion I have to say that I am personally unknown to either gentleman.

I remain, Sir, your obedient Servant,

Bristol, August 28.

FAIR PLAY.

P.S.—I enclose my card.

Foreign Department.

FRANCE.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

Discussion on Syphilisation.

THIS discussion was resumed on the 10th of August by a speech at great length from M. BEGIN, followed on the 17th by MM. MALGAIGNE and RICORD, when the subject was again postponed to an extraordinary sitting on the 21st. At this meeting, after hearing M. MICHEL LEVY, M. GERDY, and M. BEGIN, the Academy came to the resolution to accept the report; MM. Malgaigne and Depaul alone refusing to vote either for or against it. The Academy also resolved that the report of the committee, and of the discussion in the Academy, should be transmitted to the Minister of the Interior, Agriculture, and Commerce. The question may therefore be considered as definitively settled against the employment of the inoculation of syphilis, both as a prophylactic and curative agent. But with regard to the various minor points relative to the transmissibility of syphilis to animals, and to the possibility of a second attack in the same subject during life, no vote has been taken; and, therefore, as far as the Academie de Médecine is concerned, the question is still an open one.

ACADEMIE DES SCIENCES.

At the meeting of the 9th August, M. BLANDET, communicated the result of his experiments on the preservation of blood. He asserts that the chloride of

barytes combines the good qualities of the sulphate of soda and the chloride of zinc, without either blackening or precipitating the blood, so that by preparing it with this salt, it may be injected into the arteries of the subject, which by these means will be preserved from putrefaction, and also regain its natural colour. If this is the case, it will be highly useful in the preparation of specimens of morbid anatomy.

At the same sitting M. THENARD read a report on a memoir of M. Lecanu, entitled *nouvelles chimiques sur le sang*. The object of this memoir is to describe more accurately than he had hitherto done, the composition of the blood-globules. In order to accomplish their examination with sufficient accuracy, it is necessary to separate them most carefully from the serum in which they swim, and to do this, M. Lecanu adopts the following process:—The blood, as it escapes from the vein, is received in a saturated solution of sulphate of soda, at a temperature of 12° Reaumur, after which it is filtered, when the globules alone are left upon the paper; the serum, on the contrary, holding in solution all the fibrin that passes through. The blood-globules thus obtained consist of hæmatosin, globuline, a trace of albumen, a fibrous envelope, animal matter (*extractive*), fatty matter, various salts,—as the chlorides, phosphates, and carbonates of the alkalies; and, lastly, of water holding all these but the envelope in solution.

M. Lecanu appears to have established the fact, that the blood-globules do not contain any fibrin, and merely a trace of albumen; whilst the serum, on the contrary, has no hæmatosin or globuline in its composition. To prove that the fibrous envelope is not identical with fibrin, it is only necessary to examine it when submitted to a solution of caustic potass, which easily dissolves the fibrine, but leaves the envelope intact. M. Thenard concludes his report by inviting attention to the following points—which he thinks worthy of further investigation, viz., a careful examination of the composition of arterial as compared with venous blood, more especially as regards the hæmatosin, the globuline, and the envelope of the globules. To show the action of oxygen and other gases on the two varieties of blood, and the difference between the effects of these gases on the blood within the body, and when removed from it; the phenomena attendant on coagulation; the difference between the composition of chyle and perfect blood; and, finally, the analogy between the composition of the envelope of the blood-globule and the coats of the arteries and veins. These are, indeed, subjects worthy the attention of English as well as French physiologists.

On the Use of the Seeds of the Hemlock in lieu of the Leaves, in the Cure of Cancer.

MM. DEVAY and GUILLERMOND, of Lyons, having published an essay on the use of the active principle of conium in the cure of cancerous affections, the subject has been discussed in the *Bulletin Général de Thérapeutique*, from which we extract the following remarks:—M. Devay accounts for the neglect into

which conium has fallen by conjecturing that in former times the whole plant was used, including the seeds in which he supposes the active principle to reside in a high degree; whereas the leaves are now the only part of the plant directed to be employed, and, consequently, if his theory is correct, are not worthy of the confidence in which conium was held by Stork, Hoffman, Cullen, and many of the older physicians. M. Devay recommends the simultaneous employment of conium externally and internally, and asserts, that in the early stage of scirrhus of the neck of the uterus, if so applied, a cure may in many instances be expected. This disease is so little amenable to medicine, that we should be inclined to adopt any measures which are at all likely to lead to a successful result; and therefore when we find that a reason can be given for modern failures, we are tempted to hope that such accurate observers as Hoffman and Stork have not misled themselves and us in the way which is now generally attributed to them. M. Devay describes the frequent occurrence of headache, colic, diarrhoea, and trembling of the body during the use of the medicine, but does not discontinue it on that account. He advises us to begin with half a grain of the dried seeds in the form of a pill, which is to be gradually increased till the patient can take four or five grains twice a day. For the employment of the seeds as an injection, one drachm should be steeped for a few minutes in an ounce of boiling water, then immediately filtered, and injected when cold into the vagina. As an external application to malignant tumours in other situations, M. Devay recommends what he calls *baume de conicine*, which, however, is too complicated in its preparation for any one but a professed pharmacist, and we must therefore refer our readers who may wish to give it a trial to the treatise itself, or to the journal from which we have made the above extract.—*Bulletin Général de Thérapeutique*, 15 et 30 Juin.

GERMANY.

ANIMAL CHEMISTRY.

1. *On the Presence of Casein in the Blood.*—Several French chemists, amongst whom we may enumerate Guillot, Leblanc, and Stas, and Panum, of Copenhagen, have recently asserted that they have detected casein in the blood during pregnancy; Lehmann has, however, shown that the tests on which they relied apply equally to albuminate of soda, which, like casein, forms a membrane on the surface, if its solution be heated. The subject has been reinvestigated during the last few months, by Moleschott, who finds that he can detect casein in the blood after the entire removal of the albuminate of soda. This is accomplished (in his opinion) by first coagulating the free albumen in the warm-bath, and then by repeatedly boiling the filtrate with a neutral alkaline salt till no additional precipitate is thrown down. On the removal of the precipitate the filtrate is heated with sulphate of magnesia, and allowed to stand twelve or fourteen hours, to allow of the separation of the phosphoric acid. On heating the clear supernatant fluid there is a precipitate of the well-known compound of casein and magnesia. Acetic acid and rennet also gave the ordinary indications of casein in

the fluid, after the removal of the albumen and albuminate of soda. By these means Moleschott seems to have established the presence of casein in the blood of oxen, calves, sheep, and pigs; and it may thus be presumed that it is a normal constituent of the blood generally. In connection with this subject we may observe that M. S. Schultze (in a recent number of *Liebig's u. Wöhler's Annalen*) has distinctly proved that casein is a regular constituent of the middle arterial coat, and that it also occurs in the areolar tissue and the ligamentum nuchæ.—*Arch. f. Physiol. Heilk*, 1852, No. 1.

2. *On a Test for Inosite, or Muscle-Sugar.*—Many of our readers may recollect that about two years ago Professor Scherer, of Würzburg, discovered a peculiar variety of sugar in the fluid of flesh, to which he gave the name of inosite. He has recently ascertained that the following is the best method of testing for this substance:—On evaporating almost to dryness a mixture which contains inosite with nitric acid on a platinum-spatula, and treating the residue with liquid ammonia and a little chloride of calcium, and then again evaporating to dryness, we observe on the platinum spatula a *vivid rose-red colour*. If a mixture of inosite and nitric acid be slowly evaporated, the residue dissolved in water, and the solution allowed to stand for some time in a closed glass vessel, a species of mould or fungoid growth is developed on it, and on afterwards applying the above test a deep violet-brown colour is developed in place of the rose-red tint.—*Scherer in Verh. d. Phys.-Med. Ges. zu Würzb.* Vol. 2, No. 14. 1852.

3. *On Certain Chemical Constituents of the Fluid of the Spleen.*—In a former memoir on this subject, Scherer demonstrated that the expressed juice of the spleen contained lactic, acetic, formic, butyric, and uric acids, and a substance closely allied, chemically, to uric or xanthic oxide, to which he gave the name of hypoxanthin.* He has now ascertained that it also contains:—

1. A nitrogenous, crystallizable substance, to which he applies the name of *lienin*, consisting—

Of Carbon	53.71
„ Hydrogen	8.95
„ Nitrogen	4.82
„ Oxygen	32.52

100.00

2. An albuminous substance, rich in iron.

3. Much iron, in combination with acetic and lactic acids.

4. A highly carbonised pigment, of the same character as the pigments found in the urine and the muscular juice.

—*Scherer in Ibid.*, No. 19. 1852.

4. *Chemical Investigations in Cholera.*—When the cholera was prevalent at Breslau, in the winter of 1849-50, Dr. Middeldorpf instituted a series of researches on the chemical characters of the excretions,

and on the changes which some of the tissues (especially the muscles) undergo. The following are his most important conclusions:—

The filtered *intestinal discharges* were examined in the early stage of the disease in twenty-eight cases; in six of these no albumen was found; in three cases, in which it was determined quantitatively, it averaged 0.37 per cent.

The *urine* was examined for albumen in seven cases; it was present in all, the mean quantity being 0.499 per cent. The specific gravity rose as the amount of albumen increased.

Pieces of muscle as free as possible from fat and blood, were taken from the bodies of patients immediately after death. They were of a dark colour, and had a dry appearance. Middeldorpf found as a mean of six experiments, that when dried, at 170° Fah., they lost 75.808 per cent. of water, the normal per centage of water being 80, according to the recent investigations of Schottin. Hence the muscle may be regarded as drained of its water to the extent of about four per cent.—*Middeldorpf in Günsb. Zeitsche.*, Vol. 3., No. 1, 1852.

5. *On the Chemical Constituents of the Sweat.*—This subject has been recently investigated by Schottin in Lehmann's Laboratory, and with the assistance of that eminent chemist. Under the general term *sweat*, the author includes the insensible perspiration, the liquid secretions of the perspiratory glands (the true sweat in the strictest sense of the word), and the secretion of the sebaceous glands. In warm days he was able to collect, (by various ingenious contrivances,) as much as from twenty to thirty grammes [from about half an ounce to an ounce] in four or five hours, from a person taking pretty sharp exercise.

On a microscopic examination the sweat was found to contain epithelium, (in considerable abundance,) free fat mucous corpuscles, granular corpuscles, and molecular dark-coloured granules.

The reaction of the sweat was always acid, except in two cases, in which it was neutral. Urea was present in these two cases.

Nothing very distinct was established regarding the pigment, except that it differed essentially from the pigments of the bile and urine.

In 100 parts of sweat there were contained:—

Water	97.75
Epithelium	0.42
Substances not volatile .. } at 212° Fah. }	1.13
Ash.	0.70

In two separate analyses of the sweat of the foot and of the axilla, the insoluble salts were, to the soluble, in the ratio of 1 : 17. In the sweat of the foot the potassium was, to the sodium, as 1 : 2.53; in that of the axilla, as 1 : 1.75.

The fat obtained from the ethereal extract consisted partly of margarin and partly of cholesterin.

With regard to the volatile acids, he determined, with chemical certainty, the presence of formic and butyric acids, and showed that in all probability acetic and metacetic acids were also present.

He was unable to confirm the statement of Berzelius

* For a description of the chemical characters and composition of hypoxanthin and of inosite, (mentioned in the preceding paragraph,) we may refer our readers to the first volume of "*Lehmann's Physiological Chemistry*," published by the Cavendish Society.

and other chemists, regarding the presence of lactic acid and lactate of ammonia in the sweat.

Ammonia and its compounds occurred in such very minute quantities, (notwithstanding the assertions of previous chemists,) that he referred the new traces which occurred to the effect of decomposition.

Urea was not found in normal sweat, but was present when there was great disturbance of the function of the kidneys.

Schottin examined the sweat in two cases of intermittent fever during the hot stage; it contained no lactic acid, but a considerable quantity of butyrate of lime.

He does not appear to have examined the sweat of any diabetic patients, (indeed it is seldom that in these cases the skin perspires freely,) but he instituted the following experiment upon himself, with the view of ascertaining whether, when sugar was taken in abundance, it was excreted to any measure by the skin. During thirty-six hours he took nothing as food, except about a pound of milk-sugar. After twenty hours severe diarrhoea supervened, the stools having a strong acid reaction. The urine excreted during the whole period did not exceed six ounces. He collected the sweat during the last six hours, but could detect neither sugar nor lactic acid in it.

In order to ascertain whether iodine passed off by the skin he took daily half a drachm of iodide of potassium. After the fifth day he could detect iodine in the sweat.

After taking two drachms of salicin, he failed in detecting any trace of salicylous acid (by means of perchloride of iron) in the watery solution of the alcoholic and ethereal extracts of the sweat.

He similarly failed in obtaining any evidence of quinine in the sweat after taking a dose of twelve grains before entering a vapour bath.

The following non-nitrogenous acids are separated by the skin, partly free, partly in combination, namely,—tartaric, succinic, and benzoic acids. As benzoic acid when taken into the stomach only appears as hippuric acid in the urine, it is not very easy to understand how it appears unchanged in the sweat. Schottin instituted a series of ingenious experiments to explain this apparent discrepancy, but without any definite result.—*Schottin in Arch. f. Phys. Heilk.* 1852. No. 1.

Reviews.

On the Diseases of the Kidney, their Pathology, Diagnosis, and Treatment, with an Introductory Chapter on the Anatomy and Physiology of the Kidney. By GEORGE JOHNSON, M.D., Lond., Fellow of the Royal College of Physicians, Assistant Physician to King's College Hospital. London: Parker and Son, 1852. 8vo, pp. 517. Wood-cuts.

THE researches of Mr. Bowman in the anatomy and physiology of the kidney, have left nothing for any of his successors to accomplish, at all

events until the powers of the microscope are increased, and therefore we are not surprised that Dr. Johnson has merely repeated the descriptions of the minute structure of the kidney, so clearly and beautifully given by Mr. Bowman, in the "Philosophical Transactions," and copied by Dr. Johnson in the "Cyclopædia of Anatomy and Physiology." Article—*Ren*.

But Mr. Bowman had left untouched the pathology of these organs, and to fill up this hiatus, Dr. Johnson contributed two papers to the Medico-Chirurgical Society, which were published in the twenty-ninth and thirtieth volumes of their "Transactions." These papers form the groundwork of the present volume, which, however, is enlarged by the addition of chapters on the various points connected with the kidney, which were not comprehended in the above papers.

The first chapter is devoted to the anatomy and physiology of the kidney, and is as we before remarked, only a repetition of Mr. Bowman's discoveries, with the addition of a very good analytical examination of the urine. In the second chapter we find a description of the causes of renal disease, which Dr. Johnson regards, in common with all our modern pathologists, as invariably connected with a morbid condition of the blood, either introduced from without, or produced in the body of the individual.

The third and fourth chapters comprise the most important part of the volume, being devoted to a consideration of the two most common diseases of the kidney—viz., the acute nephritis of ordinary authors, and Bright's disease. These our author designates respectively, "acute and chronic desquamative nephritis," considering the desquamation of epithelium to be as much a part of the disease, as is that of the cuticle essential to the full development of scarlatina. Dr. Johnson believes that this desquamation is a part of the natural restorative process, and is the result of an effort made by the cells to eliminate from the blood some abnormal products—some materials which do not naturally enter into the composition of the renal secretion. But when this process has resulted, as it often does, in the engorgement of the tubes by their contents, it is evident that in these tubes the process of cell growth must be greatly retarded or indeed wholly arrested. Hence the desquamation of the epithelium in the kidney, though a restora-

tive process like the desquamation of the cuticle is frequently attended by injurious results, which are entirely absent in scarlatina, for no accumulation of cuticle can possibly take place.

On the other hand, Frericks considers that the desquamation is only an accidental consequence of an effusion of albumen and fibrin, which entangles the epithelium after coagulating in the tubes, and carries it off in its escape into the pelvis of the kidney. It is a difficult task to decide upon so delicate a point, but there can be no doubt of the fact that epithelial scales are found in the urine to an enormous amount, and are perfectly diagnostic of the disease.

In order to distinguish between acute and chronic desquamative nephritis with certainty, it is necessary to examine with the microscope whether the epithelial scales are entire or disintegrated, the acuteness of the attack being capable of estimation by the proportion of perfect cells found, and also by the presence of blood corpuscles, which are rarely found in the chronic form.

The symptoms, pathology, and treatment of these diseases are given in an admirable style, and with great minuteness, indeed, so much so, that it is out of the question to attempt any analysis in the limited space we can afford. But there is one point which has caused a considerable controversy, between our author on the one hand, and Mr. Simon, followed by Rokitanski and Paget on the other. This point of dispute is relative to the primary cause of renal cysts. Dr. Johnson maintains that they are simply dilated tubes, and that there is no difficulty in tracing them through every degree of dilatation from the natural size up to cysts visible to the naked eye. He also says that with care he can always detect, in contact with these cysts, unequivocal portions of elongated tube, having the same structure as the other parts, and evidently continuous with them, though this is concealed by the tissue in which they are enveloped. On the other hand, Mr. Simon contends that they are abnormal developments of epithelial germs, his theory being that, "certain diseases of the kidney, (whereof subacute inflammation is by far the most frequent,) tend to produce a blocking of the tubes; that this obstruction, directly or indirectly, produces rupture of the limitary membrane; and that then, what should have been the intra-mural cell-growth, continues, with certain modifications,

as a parenchymic development." For the arguments *pro* and *con*, we must refer our readers to the book itself, for though highly interesting they are too long for insertion.

Another disputed point is as to the development of new fibrous tissue; but here our author and Mr. Simon are both opposed to its occurrence except in very rare instances.

But it appears that desquamation does not always coexist with nephritis: and hence we must not always give a favourable prognosis on the absence of epithelial scales from the urine. Indeed, according to our author, if you have nephritis unaccompanied by this epithelial desquamation, the danger is much increased, and in chronic cases we frequently find, that instead of the morbid poison being eliminated, fatty degeneration of the kidney takes place in the granular form, terminating but too frequently in death. The mottled variety of fatty degeneration, on the contrary, is rarely preceded by non-desquamative nephritis, and is a slow insidious disease, not even to be detected by a microscopic examination of the urine.

The remaining chapters—viz., the eighth, ninth, and tenth, are occupied with a description of nephritis when followed by a secretion of pus; scrofulous disease of the kidney, cancer, and hæmaturia. Each of these sections is exceedingly interesting, but still as they have received no remarkable elucidation from the investigations of our author, we need only remark that they embody all that is known on the respective subjects.

Having thus alluded as far as our space will allow, to this highly interesting work of Dr. Johnson's, we have only to recommend our readers to examine it and judge for themselves, as to the accuracy of his views. With regard to treatment we have yet much to learn, but as we have gained one step in advance from the correct anatomy to the pathology of the kidney, so we hope hereafter to progress still further in the successful treatment of those diseases, which are even now less under the control of medicine than we hope will eventually be the case.

On a New Way of Treating Gonorrhœa. By JOHN L. MILTON, M.R.C.S. London: John Churchill. 1852. 8vo, pp. 103.

THE chief novelty in Mr. Milton's treatise consists in the advocacy of the claims of a com-

pound solution of potass, in the cure of gonorrhœa, to a front rank among the various internal remedies employed. The solution consists of the chlorate of potass, combined with the acetate and liquor potassæ, and is formed by pouring five ounces of boiling distilled water on two drachms of powdered chlorate of potass, and then adding three drachms of the liquor potassæ, and three to four drachms of the acetate of potass, after which it is to be filtered. One ounce of this is to be given three times a day, in combination with from five grains to a scruple of rhubarb, to prevent constipation; and it is said by Mr. Milton to be successful in a much larger proportion of cases than can be expected from any other treatment. But this solution is to be administered together with injections of sulphate of zinc or nitrate of silver, and we should be more inclined to put our faith in these than in Mr. Milton's panacea. However, our readers may easily try the plan, and time will show the value of the remedy.

With the above exception Mr. Milton's book is merely a good *resumé* of the ordinary treatment in the various complications met with in gonorrhœa. In gleet he advises strongly a return to the use of blisters, applied to the penis. But it is so seldom that our patients would like the confinement necessary, that we scarcely expect the plan, however good, will be extensively followed.

Provincial Medical & Surgical Journal.

WEDNESDAY, SEPTEMBER 1, 1852.

THE necessity for economy in every public charity is now so generally admitted, that we think it incumbent on the profession to take care that no undue waste occurs in the diet of our hospitals throughout the country. But when we find that the cost per bed varies as much as five pounds per annum in different establishments, we cannot avoid coming to the conclusion that the subject does not always receive the attention which it deserves. There is no doubt that the prevailing diseases in certain localities influence the expenditure very considerably, not only as regards ordinary diet, but also with reference to wine and drugs. But this will not always account for the great difference above mentioned, since it will be found that there is a great vari-

ation even in two establishments situated in the same locality, or nearly so.

We believe that the expenditure in our noble charitable institutions is frequently much increased from a want of due supervision, such as is exercised in the Poor-Law Union Houses by the Master, under the control of the Auditor. But the great difficulty seems to be, to find enough (in an infirmary for instance of 100 beds,) for such an officer to do, and therefore in nearly all of our provincial hospitals, there is no House-Steward appointed, as is the case in all the London Hospitals, we believe, without exception. The consequence is, that there is not that check upon the expenditure which we could wish, and the supply of the raw materials for the diet of the patients, as well as the staff, is left, in great measure, to a Committee of Governors, elected for that purpose; these gentlemen cannot, of course, be expected to cope with the difficulties of the undertaking so successfully as an officer whose whole business is confined to this one department; and though, in some instances, the expenditure is very low, yet in others it is raised far above the standard required.

There is, besides, a great variety in the diet itself, and in the mode adopted in cooking, which will, of course, materially affect the annual expenditure, as in the instance of meat, which loses about ten per cent more in roasting than by boiling.

There appears to be a greater uniformity in the quantity of the articles consumed by the *staff* of our union houses, gaols, and infirmaries, than could have been expected, judging from the great difference in the gross amount expended in these various institutions. At the Nottingham General Hospital, where a series of careful experiments have been carried on, each servant consumes, (and without limitation,) thirteen ounces of raw meat per day, and fourteen ounces of bread, which is rather less than the allowance to the servants of the Poor-Law Union Houses; and we are given to understand that there is general satisfaction expressed. We believe this is considerably below the average; but it should be generally known, that under favourable circumstances, such an allowance is all that is necessary. In the same hospital, also, the waste in the cooking of the article meat, is less than in most of our charitable institutions, though still greater than we believe is the case in the majority of our union houses and gaols.

At the Nottingham Hospital, one hundred pounds of raw beef and mutton will produce, boiled, from sixty to sixty-two pounds, but we conclude, that in this calculation the bones are weighed in with the raw meat; for in the Poor-Law audits we believe that, after deducting the bones, one hundred pounds are expected to produce about seventy pounds of boiled meat; and as the quality is generally better in hospitals than in union houses, the loss in the former ought to be less than in the latter, since every good manager knows that bad meat loses more in dressing than meat of a superior quality. At the above hospital one hundred pounds of mutton produce forty-five pounds and a half of cutlets, and one hundred pounds of beef, when roasted, are reduced to fifty-one pounds, carved and served out ready for distribution.

Now, when we find at other and similar institutions, one hundred pounds of raw meat, *deprived of its large bones*, produce only fifty pounds when boiled, we naturally inquire, how can this great discrepancy arise? and we are anxious to obtain information from our readers on so important a subject. We should, therefore, feel obliged, if those who have the opportunity, will forward answers on the following points, which may, perhaps, lead to still further inquiries upon other subjects:—

- 1st. The amount of cooked meat ordered on full and middle diet respectively.
- 2nd. The mode of cooking employed.
- 3rd. The quantity of boiled or roasted meat obtained from one hundred pounds of raw beef, specifying whether with or without bone.

As the saving in this article alone, if the Nottingham calculations are correct, will amount to from £50 to £80 a year in some of our charities, it is one which, we think, our readers will not consider beneath their attention; for as there can be no doubt that the patients in our various charitable institutions should have every indulgence necessary, in their respective cases, so we think that their managers are bound to see that the money subscribed is expended in such a way as to do the greatest amount of good to the greatest number.

We insert at page 456 a letter from Mr. BREE, because we think that his former exertions to improve the *Journal*, demand that considera-

tion which we are unable to extend to others, for want of space. As the matter is now under discussion by the Council, we think it right to abstain from any further remarks for the present. We cannot avoid, however, reminding Mr. BREE, that the question is not confined to Dr. COWAN and ourselves, but affects the whole Association; and that others, including ourselves, have as full a right to express their opinion as himself.

From the numerous letters we have received, we are perhaps more fully aware of the general feeling than Mr. BREE can be, and we shall at a future time be prepared to rely upon the whole body for their support against any charges which may be brought against us. It would be easy for us to occupy the columns of the *Journal* with arguments and recriminations; but this we have neither inclination, nor, we think, right to do. We would, however, simply assure Dr. TUNSTALL and others that the report of the meeting at Oxford, was really not prepared by "our reporter," but by one appointed by the publisher, under the order of the Council, and that, to guard against the charge of unfairness, we did not correct even literal errors in that part relating to the *Journal*. It is, *bonâ fide*, the official report of the Council.

Since writing the above the following resolution has been unanimously carried by the Central Council, on the 28th instant:—

Resolved,—

"That it is the opinion of this Council, that the publication of any further correspondence on the subject of the *Journal* should be avoided during the negotiation between this Council and the *Journal* Committee, for the amicable settlement of the question."

We have therefore suspended the publication of Mr. BREE's letter for the present, as well as those of Dr. COWAN, Mr. HUNT, Dr. WILLIAMS, Worcester; and Dr. WILLIAMS, Apsley Guise.

Medical Intelligence.

(From our own Correspondent.)

LONDON, AUGUST 30, 1852.

Dr. Herbert Mayo, formerly Senior-Surgeon to the Middlesex Hospital, has departed this life since our last, at his residence at Bad-Weilbach.

A few years ago, had his decease then occurred, it would have excited a universal feeling of regret in the profession, for he had not then abandoned the legitimate practice of medicine, nor taken up with hydropathy, mesmerism, and the other crudities which, of late years, have led several of "ours" to desert their ranks, and to

join the enemy. We shall, however, endeavour to show that the subject of this brief notice had more excuse for so doing than perhaps any other practitioner, who has become a hydropath or homœopath, could adduce.

Mr. Herbert Mayo was born in Berners Street, where his father resided, on the 3rd of April, 1796, and consequently was in his 57th year at the time of his decease. He was the son of Dr. John Mayo, who was elected Physician to the Middlesex Hospital in 1788, and afterwards held a similar office in the cancer wards of that institution. After passing through the usual routine of education, and acquiring more than a respectable knowledge of the classics, Mr. Herbert Mayo became one of the pupils of the well-known Mr. Joberns, at that time one of the surgeons of the hospital to which his father was attached, and under him he carried out a course of study calculated to render him eminent in his profession. On the 17th of May, 1818, he was appointed one of the house-surgeons, and in that capacity he performed his duties most rigidly and with great skill, paying great attention to the unfortunate sick under his care, and endeavouring in every way to advance the interests of the students, and to assist them in the acquirement of knowledge. His studies were especially directed to that branch of physiology which is connected chiefly with the nervous system—a subject which had been taken up with great ardour by one of the colleagues of Mr. Joberns, the late Sir Charles Bell. Mr. Mayo was engaged for some time assisting Sir Charles in his experiments on the brain, and on the relative functions of the anterior and posterior columns of the spinal cord. Indeed so much occupied was he in these matters, and so closely did he give his attention to it, in the performance and registration of the experiments, and in making and carrying out the investigations, that at last he considered himself entitled to claim a higher rank than that of the mere assistant, and boldly asserted that to him and not to Sir Charles Bell, was the merit due for certain of the discoveries which had been made as to the functions of nerves in the course of their inquiries. This naturally led to the severance of their friendship, and an occasional paper war extending over a considerable period of time.

Meanwhile Mr. Mayo, then in his 28th year, commenced a course of lectures on anatomy and physiology in a school situate in Berwick Street, Oxford Street, where he had a good class, to whom he unfolded the mysteries of the nervous apparatus, as far as they were then known. About 1828 he became the worthy successor of Sir Charles Bell, at the Hunterian School in Great Windmill Street. Prior to this he had been elected to fill the vacant surgery at the Middlesex Hospital in 1827—an office which he held, till from increasing ill health, he was compelled to resign it in November, 1842.

When the proprietary institution, known by the name of King's College, was opened, in 1831, the great reputation Mr. Mayo had obtained, caused him to be selected from a host of competitors for the chair of anatomy and physiology, the museum he had prepared for the illustration of those subjects being disposed of to the College at the same time, to constitute the nucleus of a fine collection of pathological and physiological specimens. When, however, the same chair was vacated at University College, by the resignation of Dr. Jones Quain, Mr. Mayo proffered himself as one of the candidates, but was unsuccessful, with the additional annoyance of having excited feelings of distrust in the breasts of the Council of King's College.

Among the honors of the profession which he acquired in the course of his career, the professorship of anatomy and surgery to the London College of Surgeons was that which he held in the highest estimation, as stamping clearly his status in the profession. This opinion of his will be shared by the majority of the profession, as the conferring of that office on him by the Council of the College was a proof, that in their estimation at least he

held a distinguished place among the cultivators of the medical and accessory sciences.

We have not spoken all this while of Mr. Mayo's private career. Although a man of pleasant manner, and of an amiable disposition, with an agreeable address, he never attained to the possession of a large private practice, notwithstanding his high repute as a physiologist, and his real eminence as a clever practical surgeon. It is a singular fact, that his rival in physiological studies, Sir Charles Bell, was in the same predicament, neither did he ever possess what may be considered a good practice for a consulting surgeon. We believe that his receipts from his professional pursuits rarely exceeded £1000 a-year; while some of his contemporaries, with not one tithe of his general scientific or physiological acquirements, and perhaps even hardly equal to him in practical surgery, were in the habit of taking four or five times as much yearly. It would seem, had we not Sir B. C. Brodie's splendid example to the contrary, that the pursuits of science ran counter in the eye of the public to the possession of practical information, and that he who studied nerves and their functions deeply, could not, in their opinion, correctly judge when a leg should be removed, nor even how it should be done when amputation was deemed requisite.

We have occupied a great deal of space in our account of Dr. Mayo, but we trust our readers will not think we have dwelt too long on the memoir of one who would have attained a still higher position than he did, as a sound practical surgeon, and an excellent physiologist and pathologist, had he not been crippled by disease, which undermined his bodily health, destroyed his vigor, and rendered him incapable of following his professional pursuits. We do not regard it as a blameable error on his part that, under these circumstances, urged on, too, by the advice of medical friends on whose judgment he could rely, he sought relief from a plan of treatment which, when employed empirically, is denounced by the profession, but which still has some parts of its practice allied with, and taken from, legitimate medicine. The error lay in subsequently lending the value of his name to the practice itself, for, unfortunately, many will regard him as having stamped the proceeding by his adopting it, who will not know that in reality he modified it very extensively, when using it for his patients, and conjoined with it the plans and appliances of legitimate practice. May he rest in peace.

We understand, by a letter received from Jamaica, that fever has again broken out in that seemingly ill-fated ship the *Eclair*, (now called the *Rosamond*,) and that nearly a third of the crew have been sent to the Naval Hospital at Port Royal. Seven or eight men have already fallen victims to the disease, which it appears was contracted in the river St. Juan de Nicaragua, on the east coast of Mexico. It is not, however, the same kind of fever which raged so destructively in this vessel on the coast of Africa, but the common remitting fever peculiar to hot marshy districts within the tropics. It is not attended with black vomit; and yellowness of the skin is a rare occurrence, even in the fatal cases. Still it is impossible to say how far the character of the fever might have changed, had there not been, instead of a black hole, like that at Boa Vista, a well-ventilated hospital, with an efficient staff at hand for the reception of the sick.

UNIVERSITY OF LONDON.

FIRST EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE.—PASS EXAMINATION.

First Division.—John Crown Agnis, B.A., University College; John Beddoe, B.A., University College; George Buchanan, B.A., University College; Henry Bullock, adjoining St. George's Hospital; Wilson

Fox, B.A., University College; Sydney Jones, St. Thomas's Hospital; John Zachariah Laurence, University College; Frederick Moon, Guy's Hospital; James Champion Penny, St. George's Hospital; Henry Power, St. Bartholomew's Hospital; Henry Robert Silvester, B.A., King's College; John Kent Spender, King's College; Arthur Umphelby, adjoining St. George's Hospital.

Second Division.—John Henry Bartlet, University College; Samuel Athanasius Cusack, Royal College of Surgeons in Ireland; Alfred James Dale, London Hospital; John Footman, University College; Charles Moore Jessop, King's College; Henry Leach, Guy's Hospital; John Alder Vincent, Queen's College, Birmingham; William Joseph Williams, St. George's Hospital.

EXAMINATION FOR HONOURS.

Anatomy and Physiology.—Henry Power, Exhibition and Gold Medal, St. Bartholomew's Hospital; John Zachariah Laurence, Gold Medal, University College; Sydney Jones, St. Thomas's Hospital; John Crown Agnis, B.A., University College; Henry Bullock, adjoining St. George's Hospital, and Henry Robert Silvester, B.A., King's College, equals; George Buchanan, B.A., University College; Arthur Umphelby, adjoining St. George's Hospital.

Chemistry.—G. Buchanan, B.A., Gold Medal, University College; John Zachariah Laurence, Gold Medal, University College; Henry Power, St. Bartholomew's Hospital; Frederick Moon, Guy's Hospital; Henry Robert Silvester, B.A., King's College; James Champion Penny, St. George's Hospital.

Materia Medica and Pharmaceutical Chemistry.—Frederick Moon, Gold Medal, Guy's Hospital; John Zachariah Laurence, Gold Medal, University College; James Champion Penny, St. George's Hospital; Henry Robert Silvester, B.A., King's College; Sydney Jones, St. Thomas's Hospital.

Botany.—Henry Power, Gold Medal, St. Bartholomew's Hospital; George Buchanan, B.A., University College; James Champion Penny, St. George's Hospital.

ROYAL COLLEGE OF SURGEONS.

At the last meeting of the Council the following members of the College were admitted Fellows under the provisions of the recent Charter:—James Ramsay Atkins, Stoke Newington, diploma dated July 1, 1825. Henry Woodruffe Bailey, Thetford, Norfolk, Sept. 7, 1810; William Blaythwayte, Louth, Lincolnshire, Sept. 27, 1833; George Eleazar Blenkins, Whiteheads Grove, Chelsea, Oct. 7, 1836; Thomas Leigh Blundell, New Broad Street, May, 1, 1812; Peter Bossey, Woolwich, April 2, 1828; Robert Brown, Preston, Lancashire, Sept. 7, 1821; Samuel Bucknill, Rugby, March 21, 1806; Pye Henry Chavasse, Birmingham, Jan. 18, 1833; Robert Romley Cheyne, Berners Street, Jan. 31, 1834; Thomas Farquhar Chilver, New Burlington Street, Oct. 17, 1828; Marc Antony Bazille Corbin, Guernsey, Oct. 4, 1836; John Courteney, Artillery Place, May 27, 1831; Henry Curling, Ramsgate, July 28, 1837; James Stock Daniel, Ramsgate, Oct. 20, 1826; Edward Doubleday, Blackfriars Road, Oct. 6, 1820; Arthur William Dumville, Manchester, Nov. 20, 1835; Enoch Dankerley, Oldham, June 19, 1829; James Garstang, Clitheroe, Jan. 29, 1828; Raymond Gasquet, Euston Place, Feb. 15, 1811; Charles Mends Gibson, Norwich, Jan. 27, 1832; Henry Greenwood, Horsleydown Lane, Oct. 7, 1814; John Hainsworth, late of Lincoln, Sept. 10, 1830; Samuel Hare, Langham Place, Feb. 3, 1809; Wintour Harris, Clapham Road, April 21, 1835; William Heane, Bury St. Edmunds, June 2, 1834; James Torry Hester, Oxford, June 1, 1821; Francis Edward Hicks, Henrietta Street, Cavendish Square, Feb. 17, 1832; Charles Hogg,

Finsbury Place South, May 27, 1836; Wm. Hughes, Lamb's Conduit Street, Nov. 1, 1816; William Barclay Hutchinson, Guildford Street, Dec. 4, 1829; Henry Derriche Jones, Soho Square, May 8, 1835; William Jones, Weston-super-Mare, Oct. 7, 1836; George Kelson, Sevenoaks, Feb. 7, 1817; Edward Lacy, Poole, Dec. 6, 1822; John Lavies, Great George Street, Oct. 15, 1819; William Lloyd, Army and Navy Club, Oct. 15, 1813; Charles James Malton, Upper Seymour Street, April 15, 1836; Miles Marley, Cork Street, May 5, 1820; Thomas Leman Matthews, Orsett Terrace, Hyde Park, Jan. 7, 1820; Thomas Mellor, Manchester, March 21, 1834; James Nichols, Savile Row, Sept. 21, 1827; George Ord, Brixton Hill, Feb. 8, 1831; James Phillips, Bethnal Green, March 21, 1828; Lewis Powell, John Street, Berkeley Square, Feb. 6, 1818; David Price, Margate, May 15, 1812; John Pyle, Oxford Terrace, Jan. 5, 1836; Thomas Radford, Manchester, August 1, 1817; George Rawbone, Chelsea, Oct. 4, 1822; George Sylvanus Snowden, Ramsgate, Sept. 17, 1830; William Sole, St. Neots, June 19, 1829; George James Squibb, Orchard Street, Feb. 2, 1821; Charles Frederick Staunton, Royal Artillery, Woolwich, Nov. 12, 1830; Thomas Stevenson, Upper Grosvenor Street, Dec. 7, 1821; Richard Stokoe, Peckham Rye, Feb. 13, 1829; Frederick Symonds, Oxford, April 28, 1837; William Thomas, Pembroke Dock, Jan. 17, 1823; Charles Tunaley, Millbrook Place, April 13, 1830; Thomas Ward, Southgate, Oct. 21, 1831; Henry Watson, Half-Moon Street, July 17, 1835; George Webster, Sussex Gardens, Feb. 25, 1831; William Corner West, Great Malvern, April 29, 1833.

The next professional examination for this distinction will take place in December next.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Members on Thursday, August 12th:—John Allinson, Penrith, Cumberland; Norris William Best, Wednesbury, Stafford; George Augustus Blake, London; Edward John Complin, London; James Hartley, Settle, Yorkshire; Robert Heslop, Manchester; James Hurd Keeling, Edinburgh; James Kerr, Leeds, Yorkshire; James Shepherd, Northallerton; John Smith, Daventry, Northamptonshire.

Gentlemen admitted Members on Thursday, August 19th:—George Vinicombe Coates, London; John Brandon Carguven, St. Kew, Cornwall; Bernard Haldan, Preston; Benjamin Hunt, Napton, Warwickshire; Amos Ingham, Hebden Bridge, Yorkshire; James Scarborough Loe, Leeds; Thomas Maltby, Shelton; Thomas Alban M'Manns, Hull; William Niven, London; Thomas Walton, Hull.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen will observe that the Annual Subscriptions become due on the First of January, those who have not yet paid their subscriptions for the CURRENT YEAR, or who are in ARREARS, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association, Worcester.

J. P. SHEPPARD.

Worcester, August 17th, 1852.

Secretary.

TO CORRESPONDENTS.

Communications have been received from Dr. Cowan; Dr. Tilt; Dr. Hake; Mr. Hunt; Dr. Williams, Apsley Guise; Hospital Reports, (no signature—supposed Nil Desperandum); Dr. Copeman; Dr. Day; Mr. Cowley; Dr. Cotton; Dr. Tunstall.

ALLSOPP'S PALE OR BITTER ALE.

IN consequence of the REPORTED ADULTERATION of BITTER BEER, Messrs. SAMUEL ALLSOPP and SONS have received numerous incidental TESTIMONIALS to the excellence, purity, and salutary effects of their ALES. They consider it due to the Medical Profession, who have so long recommended ALLSOPP'S PALE ALE in all cases where dietetic regimen is required, to give publicity to these Testimonials, as a means of disabusing the public mind of any possible prejudice on the subject.

By the following extracts among a number from the most eminent Medical Men, the Profession throughout the country will have the satisfaction of finding their just appreciation of the remedial advantages of ALLSOPP'S PALE ALE amply confirmed by the concurring testimony of the most able Physicians and Surgeons, as well as the most illustrious Chemists of the time:—

FROM BARON LIEBIG.

"The specimens of your PALE ALE sent to me have afforded me another opportunity of confirming its valuable qualities. I am myself an admirer of this beverage, and my own experience enables me to recommend it, in accordance with the opinion of the most eminent English Physicians, as a very agreeable and efficient tonic, and as a general beverage both for the invalid and the robust.——"Giessen, May 6."

FROM PROFESSOR GRAHAM, F.R.S., UNIVERSITY COLLEGE, LONDON; AND PROFESSOR HOFMANN, Ph.D., F.R.S., COLLEGE OF CHEMISTRY, LONDON.

"The sifting nature of the chemical examination which the Beers of Messrs. ALLSOPP'S manufacture for many months past have been subjected to, fully establishes their incontestable purity. The process of brewing PALE ALE is one in which nothing but Water and the best Malt and Hops of the first quality are used: it is an operation of the greatest delicacy and care, which would be entirely ruined by any tampering with the materials employed.——"London, April 26."

FROM THE ANALYTICAL SANITARY COMMISSIONER OF THE "LANCET," MAY 15, 1852.

"From the pure and wholesome nature of the ingredients employed, the moderate proportion of alcohol present, and the very considerable quantity of aromatic anodyne bitter derived from hops contained in these Beers, they tend to preserve the tone and vigour of the stomach, and conduce to the restoration of the health of that organ when in a state of weakness or debility. They resemble, indeed, from their lightness, a *wine of malt*, rather than an ordinary fermented infusion; and it is very satisfactory to find, that a beverage of such general consumption is entirely free from every kind of impurity."

FROM SIR CHARLES M. CLARKE, BART., PHYSICIAN TO HER LATE MAJESTY THE QUEEN DOWAGER.

"I have frequently recommended BITTER ALE medicinally, and when my home-brewed Ale has been exhausted, I have been supplied with Ale 'from your brewery.'——"Wiggington Lodge, May 2."

FROM THOMAS WATSON, M.D.

"In the genuineness and salubrity of PALE ALE and BITTER BEER, as manufactured at Burton, my confidence remains unshaken.——"Henrietta Street, Cavendish Square, May 5."

FROM GEORGE BUDD, M.D., SENIOR PHYSICIAN OF KING'S COLLEGE HOSPITAL.

"I did not want any testimony to satisfy me of the perfect purity of the PALE ALE manufactured by you. A close observation of its effects upon myself and upon many others to whom I have prescribed it long ago, convinced me, as much as the most searching chemical analysis could do, that it contains nothing more than malt and hops, and that it is a first-rate beverage.——"Dover Street, May 1."

FROM MARSHALL HALL, M.D., F.R.S.

"My confidence in the purity of your PALE ALE remains unshaken, and my opinion of its great value in a dietetic and remedial point of view, is entirely confirmed by long time and experience.——"Grosvenor Street, April 30."

FROM BENJAMIN TRAVERS, ESQ., F.R.S.

"I do not hesitate to affirm, that no deleterious substance is employed in ALLSOPP'S PALE ALE and BITTER BEER, and that my confidence in its wholesomeness as a beverage remains unshaken.——"Green Street, April 30."

ALLSOPP'S PALE OR BITTER ALE

May be obtained in Casks of all sizes from the BREWERY, BURTON-ON-TRENT; and from the undermentioned BRANCH ESTABLISHMENTS:—

LONDON, at 61, KING WILLIAM STREET,
CITY;
LIVERPOOL, at COOK STREET;
MANCHESTER, at DUCIE PLACE;

DUDLEY, at the ROYAL BREWERY;
GLASGOW, at 115, ST. VINCENT STREET;
DUBLIN, at ULSTER CHAMBERS, DAME
STREET;

BIRMINGHAM, at MARKET HALL;

At either of which places a list of respectable parties who supply the Beer in Bottles, (and also in Casks at the same prices as from the Brewery,) may at any time be seen.

**SYDENHAM COLLEGE MEDICAL SCHOOL,
BIRMINGHAM.**

SESSION 1852-53.

COUNCIL.

Robert Abercrombie, West Bromwich; John Y. Arrowsmith, Shrewsbury; George Ayton, Kenilworth; George Bakewell, Longton; Samuel Bennett, Shiffnal; Robert Blakie, Oswestry; P. Blakiston, M.D., F.R.S., St. Leonards; John Calvert Blanshard, Wolstone; William P. Brookes, Much Wenlock; Samuel Bucknill, Rugby; John Bury, Coventry; Edwin Chesshire, Birmingham; Alfred Cooper, Leicester; John Day, Esq., Walsall; Edward F. Dehane, Wolverhampton; A. Augustus Fletcher, Esq., Walsall; George Haines Fosbroke, Bidford; H. W. Hare, Aldridge; Thomas Hazlehurst, Claverley; Joseph Heeley, Stone; Thos. Wheatley Hiron, Warwick; Joseph Hodson, F.R.S., London; William Hodgson, Nottingham; George Horton, Bromsgrove; Robert Hughes, Stafford; Henry Johnson, M.D., Shrewsbury; William Jones, M.D., London; Edward Knight, M.D., Stafford; Thomas Eaton Lander, Shiffnal; William Laxon, M.D., Coventry; William Henry Partridge, Birmingham; James Paxton, M.D., Rugby; John Phillips, Bridgnorth; John Prichard, Leamington; Frederick Pritchard, Stratford; Frederick Ryland, Birmingham; Henry Lilly Smith, Southam; William Smith, Redditch; Charles Somerville, Bloxwich; William Tarleton, Birmingham; John Thompson, London; Richard Thursfield, Broseley; Thomas Thursfield, Kidderminster; Nathaniel Troughton, Coventry; Cornelius Waddle, Stafford; Fryer Webb, Wellington; George H. Whympier, Walsall; Wm. Wood, M.D., Shrewsbury; George Wyman, Alcester.

The SENATE is formed by the Lecturers, who are *ex-officio* members of the Council.

Principal—BELL FLETCHER, M.D.

Treasurer—JAMES RUSSELL, M.D.

Honorary Secretaries—ALFRED BAKER and ALFRED HILL.

The Lectures in the various departments will be as follows:—

Anatomy, Physiology, and Pathology—John White Keyworth, M.B.

Descriptive and Surgical Anatomy—George Elkington, Frowd Jones, and John Postgate.

Principles and Practice of Medicine—Bell Fletcher, M.D., F.R.C.P., Physician to the Birmingham General Hospital.

Principles and Practice of Surgery—Alfred Baker, Surgeon to the Birmingham General Hospital.

Midwifery, and the Diseases of Women and Children—Francis Elkington, M.D., Senior Medical Officer to the Lying-in Hospital, and V. W. Blake.

Therapeutics and the Treatment of Disease—James Russell, M.D., Physician to the Birmingham General Dispensary.

Materia Medica and Pharmacy—John Bassett.

Theoretical and Practical Chemistry—Alfred Hill.

Systematic and Structural Botany—Frederick Westcott, As.L.S.

Forensic Medicine—William C. Orford, Surgeon to the Birmingham General Dispensary.

Further particulars may be obtained by application to the Principal, or to any of the Lecturers.

The WINTER SESSION will Commence on MONDAY, OCTOBER 4th, with an Introductory Lecture by BELL FLETCHER, Esq., M.D.

**SCHOOL OF MEDICINE,
CHATHAM STREET, MANCHESTER.**

THE SESSION 1852-53 will commence on FRIDAY, OCTOBER 1st, when the INTRODUCTORY ADDRESS will be delivered by Mr. DUMVILLE, at Four P.M., after which the SCHOLARSHIP and PRIZES for the past year will be presented.

WINTER LECTURES.

Medicine—Dr. Watts.

Clinical Medicine—Dr. Eason Wilkinson.

General Anatomy and Physiology—Mr. Dumville.

Surgery—Mr. Southam.

Practical and Surgical Anatomy—Mr. J. S. Fletcher and Mr. J. O. Fletcher.

Demonstrations and Superintendence of Dissections—Mr. Murphy.

Chemistry—Mr. Stone.

SUMMER LECTURES.

Obstetric Medicine—Dr. Whitehead.

Diseases of Children—Dr. Merri.

Forensic Medicine—Dr. Aikenhead.

Botany—Dr. Jepson.

Materia Medica and Therapeutics—Mr. Somers.

Pathology—Dr. Watts.

Diseases of the Eye—Mr. Armstrong Todd.

Practical Chemistry—Mr. Stone.

Hospital Practice at the Royal Infirmary, where Clinical Lectures on Medicine and Surgery are regularly delivered.

Examinations of the Classes will be held regularly by the Lecturers; and Scholarships, Prizes, and Certificates of Honour given to Meritorious Students at the end of the Session.

CLINICAL PRIZE OF TWENTY GUINEAS.—The Lecturers have had placed at their disposal, by a friend of the School, Twenty Guineas, to be awarded to the Student who shall distinguish himself by Reports and Observations on not fewer than Twenty Medical and Surgical Cases which may occur in the Hospital.

G. SOUTHAM, Registrar.

Chatham Street, Piccadilly.

August, 1852.

BARON LIEBIG'S OPINION OF "PALE ALE."—The prominence given to the name of Baron Liebig in placards and advertisements will have created the impression that he coveted a celebrity inconsistent with the dignity of his station in the scientific world. Having learned that he had attained such undesirable notoriety, Baron Liebig has requested the publication of the following letter, with the view of informing the public of the motives which dictated his communication to Mr. Allsopp:—

"The question of adulteration by strychnine, which has been taken up seriously in England, seemed to me of great importance, and I thought to do some good by aiding to demonstrate the error. If I wished to associate with any individual brewery my remarks on the alleged adulteration of bitter beer with strychnine, it would have been natural to have mentioned another brewery, in which alone, and not in Mr. Allsopp's, I was engaged in investigating the Burton mode of brewing; and it was also in that other brewery the Bavarian brewers acquired all the instruction they obtained at Burton. The admiration I expressed of this beverage in my letter to Mr. Allsopp is advertised in such a manner as to lead to the inference that my praise was exclusively confined to Mr. Allsopp's beer; this was not the case; my remarks referred to that class of beer."

"JUSTUS LIEBIG.

"Giessen, July 24, 1852."

LECTURES ON THE DISEASES OF CHILDREN,

DELIVERED IN THE

Chatham Street School of Medicine, Manchester.

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Vienna, etc.

LECTURE XIII.

Treatment of continued fever in its hypersthenic and asthenic stages.—Local affections (apparently inflammatory) which arise in the hypersthenic stage, require moderation in the use of debilitating means; the fever itself, uncomplicated, if present in infants, requires a bland and expectant management, in spite of high hypersthenic symptoms. Above that age some remedies admissible. Sponging with cold water. Two asthenic forms, and their treatment. Complications—diarrhœa, and angina; treatment.

GENTLEMEN,—Having to speak at present of the treatment of continued fever in its *hypersthenic and asthenic stages*, I beg you to remember the principles mentioned when we spoke of the management of continued fever within the first day or two. You will continue to follow, with a vigilant eye, the state of the head, throat, and abdomen, and combat local affections and complications, if there are any. A degree of erythematous angina is not unfrequent at that stage. But, although the hypersthenic symptoms may appear high and tumultuous, let me recommend moderation in the use of active remedies against local affections, particularly in leeching and the employment of the emetic. We must pay attention to this. That kind of local affection which may appear as inflammatory, showing itself under very high temperature, and dryness of the skin, with the pulse above 160, does not admit of such powerful antiphlogistic treatment, as if the same local affection had appeared in the form of *primary* inflammation, under less heat, dryness, and frequency of the pulse. The passage to asthenia, in this case and age, is too easy, and may be precipitated by even a moderate loss of blood. Thus, too, if signs of angina should appear about the third day of the fever, under the described hypersthenic symptoms, there is scarcely any good chance for the emetic, unless the constitution of the child and its age, be particularly encouraging. Bilious discharges must rather be gently promoted, never directly stopped by astringents, and the general bilious tint, particularly in hot summer time, counteracted by tartaric or citric acid, in solution. But if there is no salient complication, and the child be of tender age, the management must be rather abstemious from medicine. The usual way of practice in these cases, is to prescribe some saline, antimonial, or other kind of active remedy, calomel not excepted. This practice is intended to break the violence of vascular action, cool the blood

and the like, all very specious, if we could but realize them with those remedies which, uncertain even with adults, seldom fail to derange the delicate stomach of the child, or to throw a new brand into the disordered system. Abstracting from the imperfect knowledge we have, as yet, of the nature of continued fever, comparative experimentation, instituted in different continental hospitals, though not to sufficient extent yet, speaks in favour of a more bland or negative treatment of all kinds of primary fevers, including typhus. I have applied myself to the same investigation, as far as relates to infants and children, during the last six years in the hospital under my care. I am sorry I am not enabled yet to bring before you the results in exact figures; I can assure you, however, that—abstracting from local complications, which you must not overlook, and which may require some special and active treatment—in spite of the dangerous aspect of the mentioned hypersthenic fever, you will be happier in practice by withholding from such little patients, most particularly nurslings, most of those remedies. How frequently practitioners must lay aside, or change, and again change, that kind of prescription for adult patients who complain of some disagreeable effects. Nurslings cannot complain; but a careful observer will frequently have noticed more restlessness, increasing tenseness of the epigastrium, eructations, and similar symptoms, soon after a few doses.

It is not an easy thing to have before you a child in high fever, amidst an anxious family, and not to act. The homœopathists are, at any rate, in an easier position whenever nothing must be done, because their globules act at least upon the parents of the child; as to ourselves, we want not only certain firmness of mind to keep an expectative position in face of alarming symptoms, but this firmness at the same time must support us through our manner and words before the excited parents. There is, no doubt, a bland or expectant treatment in the mentioned instances, require more distinguished qualities on the side of the physician, than that which blindly deals with powerful drugs. Still, if your patient is an infant, you must try to enable yourself, by degrees, to inaction as well as action, and it may serve you as an encouragement, that the results of the Childrens' Hospital of Pesth—obtained from the examination of many hundreds of recorded cases of primary fevers of every description—speak decidedly in favor of mild or negative treatment, including fomentations, poulticing, various injections, and general sponging. I remember, amongst others, the *resumé* of 109 cases of the kind, with a mortality of 8 per cent., (very little in that age,) 20 of which have not taken internal medicines at all, and most of the 80 only occasionally, for one or other symptoms. By and by I did the same in my private practice, which increased rapidly, and to an uncommon extent, in that department of physic.

What I recommend you, therefore, in the case of uncomplicated continued fever in its hypersthenic stage, in an *infant*, is this:—reduce the quantity of milk which the infant used to take, and give frequently cold water, with sugar, to drink; only, if the patient is above

one year, or two, and no sign of gastric disorder present, then, if you think it proper, prescribe *an ounce or two* of those light acidulated mixtures mentioned in Lecture VIII.

In the case of pharyngeal irritation, the following mixture may answer the best:—R. Rad. Alth., Fruct. Tamarind, utrq., dr. iss.—iij. ; Coqu. c. aq. qu. s., p. $\frac{1}{2}$, hor. ; Ad. Colat., oz. ss.—iij. ; Adde Acidi Hydrochlor. Dilut., scr. j.—dr. ss. ; Syrup. Citri., dr. iss.—iij. S. One teaspoonful or two every hour.

Perspiration is the natural and desirable crisis, but it must not be enforced by direct internal means. The bowels should be assisted if necessary, by injections of castor oil. Most warmly I recommend you in the stage in question, to sponge with cold water the whole surface, and let it evaporate under the coverings. This (too much neglected with adults) has still more striking good effects upon the delicate and active skin of children ; it may be repeated as soon as the skin would again become hot and dry. No fear of a hidden exanthema should ever deter you.

The *treatment of the asthenic stage*, I find, must be rather active. Remember the principal symptoms. But I will bring before you *two* different forms and indications. There are, of course many varieties.

First, you may have this: under rapid increase of frequency (towards 180 and more) and feebleness of the pulse, and dryness of the skin, its temperature is high, the movements of head, eyes and limbs, show great restlessness, startings, twitchings, and occasional tremor. Under this group of symptoms, which may perhaps correspond to the erethistic stage of the nervous fever of adults, as described by Peter Frank, I have adopted with great success camphor with opium internally, and cold sponging with water and vinegar (about one-sixth part of the latter), rubbing, with flannel dipped into it, the chest, abdomen, and limbs, for a few minutes, and then rub them dry.

This form you will seldom see under three years, when a single dose should not be more than one-sixth of a grain of both Pulv. Doveri and of camphor, with some grains of sugar, all reduced to the finest possible powder, watching carefully the effect, and not to be more than two or three doses, stronger or weaker, according to the age ; if they do good at all, few doses will do so, and the improved state will commonly not admit of further repetition. Besides that, you may give a light infusion of valerian, half a scruple to the ounce, to drink from time to time, *cold*.

The signs of improvement will be: decreasing frequency of the pulse, with more turgor and less dryness of the skin, more rest, and better countenance. Another important indication you will find in this: rapid increase of frequency of the pulse, (180 and more,) and marked feebleness ; the heat of the skin decreases rapidly with the exception of the forehead, which is very hot ; torpid drowsiness or sopor, with moaning, head and eyes heavy, little or no restlessness, nor convulsive twitchings or tremors. In this case the action of opium would be almost certainly fatal. In this state I recommend you, instead of camphor, a drop or two of Spt. Ammon.

Arom., to be repeated according to its effects, and a light infusion of arnica-roots, to drink hot, from time to time. Sponging must be performed with hot camphorated brandy, rubbing at first the skin with it, energetically, and then rub it dry with warm flannel. The principal signs of improvement will be: decrease of frequency of the pulse, with simultaneous increase of heat and turgor, and more animation of movements and countenance.

Both these asthenic forms, in order to present the mentioned indications, must have been shortly subsequent to what we have traced as the hypersthenic stage.

Both are exceedingly dangerous, the latter almost constantly fatal ; both differ from what we see in adults, by the more striking appearance and progress of debility, and exhaustion of vitality. A mischievous mistake it would be, if you were misled by the soporous or comatous form, to take and treat secondary asthenic fever for meningitis. I beg therefore to remind you of the description of this disease. On the distinction from typhus—more difficult but less important—I will speak in a future lecture.

I have frequently dissected bodies of infant children, who died in these forms in four or five days, in whom I could not detect anatomical changes at all. This happens rarely with elder children, and still less with adults ; asthenic stages of different primary fevers run all much slower and longer in the latter ; and after a strict comparison, I should think, in the tender organism it cannot come in continued fever to such a degree of chemical change of the blood, as in elder individuals. Exhaustion of nervous power sooner causes death, and seems to be the more immediate agent towards death. Therefore I thought “asthenic” to be a proper term for that kind.

There have been cases in which I have prescribed quinine with camphor, from a quarter to half a grain of the former, with one-eighth of a grain to one quarter of the latter, to be repeated every two hours. The indication of this was in particular founded upon low or moderate temperature of the skin, the pulse above 160 ; and every expression of muscular languor, weakness in the spinal innervation, no convulsive restlessness, nor the signs of decided torpor as above. An essential condition for the tolerance of quinine is a soft, proportionally good state of the abdomen. This I did successfully in elder children, but with disagreeable effects in some under two years of age ; that remedy is not so proper for their tender stomachs.

And you will meet with that kind of asthenic stage consecutive to the primary hypersthenic, in different variations, gradations and shadows, on which you must found your judgment, principally upon the often-mentioned proportional relation of principal symptoms. In some instances it will not appear clearly, if the case be of the hypersthenic or the opposite character. I wish you, in these instances, to see that you see clear, and I advise, that when you see not clearly, you should fancy, before you act, that an homœopathist is at the door, or place yourself even, when you act, as if upon a level with him. Active remedies under clear circumstances,

and negative conduct under the opposite. Thus you must fight the battle against homœopathy. Thus I fought it; not directly attacking them, and attributing homœopathic progress to many causes, but not to the most real, to our own imperfections or imprudence in practice. I believe that acknowledging their negative power, in many obscure cases, suits us better than an inveterate confidence in obscure therapeutical actions against obscure maladies. This reflection finds a particular application to children's practice. Do not imagine too easily you know the pathological condition of the child, and if you think you are not quite sure, apply nothing, or quite indifferent things, as *f. e.*, tea-spoonful doses of an infusion of ipecacuanha, two or three grains to the ounce, or similar, to which some physicians even may attribute, I do not know what effect, but which may be considered as an allopathist homœopathism, sometimes required for those patients, or families, who absolutely wish to see prescriptions and medicines!

Complications of that asthenic stage, as described, are very few; if these are hidden or apparent, they date their origin from the other stage.

Diarrhœa, which we see sometimes to appear, is connected with little or no signs of pain, is thin, mostly of some brownish colour, and very offensive smell; the abdomen, not constantly distended with gases. In rare cases it is of a dirty whitish, greyish aspect.

This complication will but hasten the decline of vital power. Bilious discharges, I mentioned already, sometimes appearing at the height of the hypersthenic stage, as a good occurrence, but rare at the tender age. If so, the temperature will decrease, and the little patient show more rest, which you will not mistake for commencing asthenia, if you find that along with the heat also the frequency of pulse decreases.

It wants not to be repeated, that bilious discharges, green at the very moment of the discharge, must not be directly suppressed; sometimes even under the presence of the asthenic character of fever, when scarce, rather promoted by bland doses of castor oil. Hence it follows, that if at the stage of transition towards, or even at the apparent beginning of the asthenic stage, you should happen to find dirty whitish discharges, without trace of bile, and the right hypochondrium tense, you may adopt the following indication:—From a quarter to half a grain of calomel, or more, according to the age, to be repeated every two hours, until the effect becomes manifest. If, however, those whitish discharges are copious, then it would be imprudent to give more for a dose than one-sixteenth or one-twelfth of a grain.

As to the other bad kind of diarrhœa, thin, dark coloured and fetid, under a rapid progress of asthenic symptoms, little can be done against it by direct remedies. To stop it in these cases by opium, is the most dangerous plan. If there is any good chance, it must follow the above-mentioned treatment by internal and external stimulant means, upon the nervous system, and the skin, to which, if the skin has a moderate or low temperature, you may add hot poultices, with one-eighth

part of mustard, made up with brandy instead of water, on the abdomen.

If, during the hypersthenic stage, symptoms of active congestion, in the brain, lungs, or liver, were present, these in the asthenic stage, will disappear, or take up a passive character, unmanageable by active antiphlogistic means. The skin, being now in a more dry and less active condition, will allow the use of sinapisms, not to be carried, however, to too strong an effect; and no blisters, which easily might cause unhealthy ulcerations.

Angina of any kind if it was present at the other stage, will have the same lot of passing into a passive state. Slight degrees of swelling, under the fatal progress of asthenia, I have seen to disappear. Pharyngeal ulcerations take up an unhealthy aspect, dirty-pale surface, and pale all around; in some cases, however, we observe a livid aspect, which, if the asthenic stage continues some days, may pass into sphacelous sloughing. The greater the debility, the less good you can expect in these cases, either from the internal use of the above mixture, with hydrochloric acid, or the local application of the caustic. You must rely upon the internal and external stimulant plan, as recommended in this lecture, and locally touching by a sponge with camphorated brandy.

If in young children you succeed to check the progress of the asthenic stage, and to resuscitate vital energy—manifested by those changes of the skin and the pulse which I have already indicated—still the recovery will be slow. And remarkable it is, that whilst the more rapid progress towards recovery immediately from the height of the hypersthenic stage, shows a more or less striking critical action, by perspiration: the slow recovery from the asthenic stage will manifest nothing, or very little, of that visible crisis.

In some cases asthenia, subsequent to the height of the hypersthenic stage, takes another course: when, on the third or fourth day, the danger of that high fever seemed to pass away, under some moisture of the skin, better pulse and countenance, still recovery will not duly go on. The head of the child seems easier, the skin less hot, and the pulse comes down towards 150 or 130, but the child is exceedingly weak, restless, and irritable, with disordered abdominal functions, and thus by-and-by the fever ceases entirely, or passes into a gastric, remittent form, puzzling your expectations. Of these forms I will speak on a future occasion, concluding with again recommending you great reserve with internal medicines. Whenever the indication in the course of a continued fever is not quite clear, rely very much upon the management of the skin. I believe I have saved more children's lives from the dangers of fever by acting upon their skins, than by their mouths.

On the whole, the hypersthenic and asthenic character of simple continuous fever are both rather rare in infants and children.

ON THE TREATMENT OF INCIPIENT HYPERTROPHY OF THE HEART.

By T. G. HAKE, M.D.,

Physician to the Bury and Suffolk General Hospital.

I AM desirous of drawing attention to the treatment of heart disease by means of inhalation. All remedies are in a certain sense applied with a view to effect local changes; but it has not been sufficiently considered that by means of endosmosis it is easy to bring our remedies into direct contact with the lining membrane of the left heart and aorta, as well as with the capillaries of the pulmonary tissue. A sedative, (for example, fox-glove or hydrocyanic acid,) suspended in the vapour of water, or in atmospheric air, and inhaled, must pass by a well-known law into the capillaries of the lungs, and accompany the newly-aerated blood which they contain through the pulmonary veins to the left auricle. The result of this process of treatment is direct, as respects the left auricle and ventricle only; but it is this side of the heart principally which becomes affected by disease, particularly by that form of it—namely, hypertrophy, which is susceptible of relief or cure by the means to be presently pointed out.

While it is impossible to cure hypertrophy of the heart in an advanced stage,* it is of great importance to know that it may be cured easily in an early form, especially when it is remembered that the affection, at first slight, is progressive, and is attended with peculiar distress to the patient from its invasion.

The method pursued by me in the treatment of this disease is the following:—I order from five to ten drops, the increase being gradual, of diluted hydrocyanic acid to be inhaled three times a day in the vapour of hot water, at the hours of eleven, three, and seven, or midway between meals. The patient is directed to lie down for one hour after each inhalation of the acid. The effect of the treatment is at once to subdue the increased impulse of the heart for the space of an hour or more after its application, and the mere rest thus acquired by the organ conduces to restore it to health. Faintness is experienced by the patient for some time after inhaling the acid, not to a sufficient degree to be distressing, yet to such an extent as to render the recumbent position advisable. In mild cases, at the end of four or six weeks, the periodical arrest of impulse produced in the heart becomes persistent, but this improvement is attended with distressing feelings of faintness, and a return of palpitation on the occurrence of exciting causes. But at this period of the treatment the organic affection has given way, the hypertrophy, or over nutrition is checked, and it only remains to restore tone to the nervous system of the

thorax by quinine and steel, aided by a liberal diet. I have pursued this plan of treatment for twelve years in the wards of the Suffolk General Hospital, and in private practice. I have never known it to fail.

I venture to call the attention of those who engage themselves in the diagnosis of heart diseases to the above brief remarks, and to predict that they will prove suggestive of new modes of treatment, not only in these, but likewise in aortic affections. I need scarcely add, that remedies of the most opposite character may be thus employed to combat the different forms of disease.

Touching the pathology of the affection under special discussion, it has been considered on high authority that hypertrophy of the ventricle cannot subsist long in its simple form, and that it is difficult to authenticate its presence before it merges into dilatation. The diagnosis of a simple hypertrophy is no doubt inferential; the local character of such an affection quickly merging into the more general form in which dilatation originates, enlargement of all the fibres necessarily giving rise to increase of the ventricular cavity. Still a simple hypertrophy is possible, but this I would not infer on the usual grounds. I would not admit that an affection of this kind, giving rise to eccentric enlargement in its bulk, without affecting the cavity of the ventricle, was simple, any more than it would be admitted generally that a similar affection, which, from its position, caused the cavity of the ventricle to be diminished, (concentric hypertrophy,) was simple.

Both eccentric and concentric hypertrophy, though thus affecting the bulk and the capacity of the heart by the same morbid process, but with a different result as respects form, may take place under a similar law to that which governs simple hypertrophy, an affection modifying neither the bulk nor the capacity of the organ in which it happens.

A simple hypertrophy, coming within the above definition, may occur in any part of the heart, whether in the superficial, reflected, or proper fibres. It may be unattended with increase of bulk, though not of density. Indeed, in true hypertrophy, with whatever changes it may otherwise be associated, the consistence of the heart is increased, though its texture remains normal. And it is constantly found that the right ventricle becomes tough to a degree unknown even in the ventricle of the left side. Now, this increase of consistence, by which true hypertrophy is characterised, can arise only after a displacement of areolar tissue and sarcolemma, and a development of muscular fibre in the heart; and when constituting the form of disease named simple, might with propriety be called centric hypertrophy, in contra-distinction to eccentric and concentric, both of which, however, are eccentric in relation to it.

There are forms of cardiac disease classed under the head of hypertrophy, in which the colour, texture, and consistence of the heart are abnormal, and might give rise to a doubt whether a true muscular hypertrophy is to be recognized as their distinguishing feature, a question which the microscope will determine. Meantime, physiologically speaking, every instance of incipient hypertrophy of the heart bears within itself

* Since this paper was written I have seen a patient who has been under the treatment here laid down for several years, at intervals. His case was originally one of the worst forms of hypertrophy of the heart from rheumatism that ever came under my notice. It is now so greatly relieved as to present only a slight form of the disease, and I believe it to be susceptible of a complete cure. I shall refer to it in a future paper.

the elements of its own increase, and while the developing process has a resemblance in this respect to that of a voluntary muscle, there is no power in the heart, as in the arm, of securing rest, and the consequence is, a disproportionate increase of bulk in the overactive organ. The purpose of treatment, therefore, is to imitate the effects of rest on a voluntary muscle, and this is fully effected by the remedy prescribed above. It must be evident that a careful diagnosis is an important antecedent of treatment in these cases. Where fatty degeneration is supposed to be blended with the hypertrophied tissue, there is already a disposition to leipothymia, which should counter-indicate the use of the acid, and reasons might easily be adduced why no success could be anticipated from its employment when the heart is flabby as well as enlarged, and its tissue is infiltrated with the products of inflammation. These points are to be judged of by general as well as special diagnosis, and by the previous history.

The causes of a true hypertrophy are often accidental, arising most frequently from overeffort of the muscular system, and from the extension of rheumatism; these occur often in the healthy, and their effects are peculiarly susceptible of cure; but where the endocardium or the valves have undergone change the bruit remains after the preternatural impulse is arrested.

I will conclude by observing that the most promising cases are those which, while classed as presenting pathological phenomena, not only from errors of relative proportion of the part affected to the entire organ, but from the numerous disturbing causes which they introduce, must be viewed as resulting through physiological phenomena. There is probably as little relative difference between the hard muscular limb of a trained man, and true hypertrophy of the heart from mechanical obstruction, on the one hand, as there is between the flabby, voluntary, and involuntary muscles of the anæmic patient on the other. Indeed it may be shown that, in ordinary development from the foetal to the mature life of the heart, a law is observed similar to that which governs its hypertrophic increase. It is in fact found, that the various parts of this organ attain their due proportions in connection with the increased demand made upon them; the ventricles enlarge as the Eustachian valve becomes closed, the auricles having their development arrested as the foramen of Botal becomes opened, or in other words, the conversion of the ventricles from a single to a double organ, is attended from the third to the fifth month, with the establishment of that due proportion between the ventricles and auricles—owing to the increased activity of the former—which, in early foetal life, was wanting, affording a normal instance of an hypertrophy proceeding in one portion in relation to another, in the same organ. At the fifth month of foetal life the left ventricle is more capacious than its fellow, but the thickness of the walls of the heart is the same on both sides. But afterwards, when the function of the left heart is called into full action, the proportionate thickness of the wall of the left ventricle to the right changes rapidly; instead of remaining equal it becomes as four or even five to one.

ON

THE TREATMENT OF DIARRHŒA AND DYSENTERY BY SULPHURIC ACID.

By EDGAR SHEPPARD, Esq., M.R.C.S., L.S.A.

THE treatment of diarrhœa and dysentery by means of sulphuric acid, of which mention was made in the various medical journals some months ago, and the efficacy of which has since been confirmed by a few practitioners, has received in my hands the most rigid and severe experimental test; and though I am averse generally to obtrude myself, and the details of my practice, upon the notice of the public, I cannot, upon this occasion, refrain from doing so, inasmuch as the facts which I propose to state are so striking, and the evidence which I am about to offer so conclusive, (to my own mind,) that I think I ought to press upon my medical brethren the propriety of testing and comparing with the olden, this modern treatment—a treatment which (for what reasons I know not) has not yet received that support and countenance from the profession to which it is most fully entitled.

Though it is true that sulphuric acid, combined with some alkali, in the shape of a neutral salt, has been frequently administered in various forms of dysentery, I believe the exhibition of it alone, and uncombined, in indiscriminate cases of diarrhœa, to be perfectly novel.

During the last six weeks I have seen upwards of fifty cases of diarrhœa, many of them being severe, some few the very worst, forms of English cholera. In only one instance have I witnessed the failure of the acid treatment, and in that instance the chalk and astringent treatment was unsuccessful also. There was only this difference between the two systems:—the acid plan seemed to have no effect upon the disease, the chalk plan actually aggravated all the symptoms to a very frightful extent.

I propose in this brief paper, first to give my readers some idea of the character of the prevailing epidemic in my locality; secondly, I purpose detailing a few of the worst cases selected from my note-book; and, thirdly, I propose to draw a few practical conclusions from them as to the comparative advantages of the alkaline and acid modes of treatment.

I. The character of the epidemic which has been so prevalent in my neighbourhood during the last six weeks, has been as follows:—Great prostration of the vital powers; severe griping and pinching pains in the bowels, (not invariable,) greatly aggravated by drinking anything hot, greatly relieved by cold; tongue generally dry and furred, occasionally moist and red; distressing flatulence, the bowels being at times very much distended; burning thirst, and sensation of heat down the whole course of the alimentary canal, with (in some cases) incessant vomiting.

II. Case 1.—I. T., seized on the morning of August 1st with violent pain in the bowels, with vomiting

and purging—a most decided case of what is vulgarly called “*upwards and downwards*.” I was sent for about nine o’clock in the evening. He complained of intense pain, which had been greatly increased by his having swallowed, about half an hour previously, a cup of hot tea, although the stomach only retained it for about five minutes; pulse feeble, 120; tongue red and moist; feet cold; intense thirst and desire for cold water, which his friends would not let him have; had had about fifteen watery rice-coloured evacuations since the morning. Nothing would remain on the stomach. I immediately gave him a dose of the following mixture, which I had taken with me in my pocket, upon his wife’s description of the case:—R. Sacchari Albi, dr. iv.; Acid. Sulph. Dil., dr. ij.; Tr. Cardamom Co., dr. iv.; Aque Menth. Pip. ad., oz. vi. M. A fourth part to be taken every four hours.—The patient had no sooner swallowed the mixture than it returned. I then ordered some cold water fresh from the pump to be procured, when I allowed him to drink as much as he desired. He immediately swallowed three tumblers full, and expressed the most intense satisfaction. “The burning heat,” he said, “was quenched.” The pain immediately ceased. The sickness did not return. In about ten minutes time I gave him another dose of the mixture, with a pill of calomel and opium, one grain each, and left him with directions to continue the mixture every four hours, and drink as much water as he wished. The following day I found my patient quite well. There had been no recurrence of either the vomiting or purging.

Case 2.—Rev. T. S. is subject every summer, being a nervous weak subject, to attacks of dysentery, which leave him in a state of great prostration. I first saw him August 3rd. The dysentery had been on him for three days, and had not yielded to his usual remedy—the Mist. Cretæ Co., with a little Tr. Opii. Great pain in the bowels; subject to, and then suffering from, ascarides; tongue dry and furred; constant nausea. Ordered the same mixture as in case 1, which afforded immediate relief. The next day my patient was convalescent, suffering only from great debility. On the 5th of August he went to Gravesend for change of air; and I gave him an ounce bottle of the dilute sulphuric acid, with directions that he should take twenty-five drops whenever he was threatened with any return of the dysentery. Gave him a turpentine enema the night previously, which destroyed a whole nest of ascarides. On his return from Gravesend, Mr. S. stated that he had had several attacks, but that they had been immediately checked by the exhibition of the drops. He complained of the chalk mixture as having invariably “clogged” the bowels, and produced constipation, whilst the acid stopped the dysentery by increasing the tone of the mucous membrane of the canal.

Case 3.—J. Q., 2 years of age. Summoned to this child early in the morning of August 6. Incessant pain in the bowels, and purging for the last eight hours; skin cold and clammy; pulse extremely feeble,

and rapid; intense anxiety of countenance. In fact, the child appeared moribund, and the parents quite thought the case hopeless. They had given a little brandy, which had been immediately rejected by the stomach. I sent for a tumbler of cold water, which the child caught sight of, and requested to have. The little thing drank off the whole, and sunk back on the pillow quite exhausted. Ordered the following mixture:—R. Acid. Sulph. dil., dr. j.; R. Cardamom Co., dr. j.; Sacchar. Alb., dr. ij.; Aq. Menth. Pip., ad., oz. ij. M. A teaspoonful every hour. I called at two o’clock p.m., when the child was sitting up in its mother’s arms, eating a piece of bread and butter. The purging had quite ceased. Mrs. Q. said “the effect of the first dose was quite magical—the child altered for the better in about ten minutes.” On the following day my little patient was running about the room when I called. Being a delicate scrofulous subject, I prescribed eight drops of muriated tincture of iron three times a day.

Case 4.—T. L., aged two years and a half. Symptoms precisely analogous to those detailed in case 3. Saw this child on Sunday evening, August 29. Ordered mixture as above. All the symptoms immediately relieved.

Case 5.—Mrs. B., a lady from Devonshire, 70 years of age, taken ill August 26. I saw her on the morning of that day. Great uneasiness in the bowels, hardly amounting to serious pain; constant vomiting and purging; tongue dry and furred; foetid breath; pulse 100; abdomen tympanitic; great thirst. Ordered iced water *ad libitum*, and the following mixture and pill:—R. Sacchari Albi., dr. iv.; Acid. Sulph. Dil., dr. iss; Tr. Cardamom Co., dr. iij.; Liq. Morph. Bimeconat., m. xl.; Mist. Camphoræ, oz. vss. M. A fourth part to be taken every four hours.—R. Hydr. Cum Cretâ, gr. iij.; Pulv. Ipecac. Co., gr. ij. To be taken as a pill immediately. On the following day I found that my patient had obtained relief in the course of two hours. Only one evacuation since my visit yesterday; pulse 88; tongue moist, and not so much furred; abdomen less tympanitic; had passed a comfortable night. She said she believed the iced water had “done wonders for her.” Rapid improvement took place, and she left here for home August 31st.

Case 6.—Mr. J., seized with violent vomiting and purging August 29th. Intense thirst and burning heat down the alimentary canal. Had been persuaded to drink hot things, which had greatly aggravated the symptoms. Flatulence and severe abdominal pain. Ordered cold spring water *ad libitum*, which checked the vomiting, followed by thirty drops of the acid, with Tr. Cardam. Co. every four hours. Immediate relief.

III. The above cases have been selected from my note-book to illustrate the *rapidity* of the cure in the treatment by the sulphuric acid, as compared with that by chalk and opium. In every case that I have seen, with one exception, the amelioration in all the symptoms

has been equally rapid. This exception occurred in one of my own servants, a delicate young woman, 25 years of age. The acid treatment did not seem to do her much, if any, good, when I immediately resorted to the following mixture, (my olden form for the treatment of diarrhoea):—R. Cretæ pp, dr. ij.; Conf. Aromat., scr. ij.; Sp. Ammon. Aromat., dr. ij.; Tr. Opii, dr. j.; Tr. Catechu, dr. iv.; Aq. Mentli. Pip., oz. v. M. A fourth part every four hours.

The first dose so aggravated her symptoms that I could not persuade her to take a second. I then returned to the acid treatment, in which she persevered for two days, being occasionally better, and then again as bad as ever. The symptoms at length yielded to the following combination:—R. Potass. Chlorat., Sodæ Sesquicarb., utr., dr. j.; Tr. Cinchonæ Co., dr. iv.; Sp. Æth. Sulph. Co., dr. j.; Infus. Cascarillæ, oz. v. M. A fourth part every four hours. A glass of port wine twice a day.

In about ten cases out of the fifty entered in my notebook, I first tried the chalk and opium treatment, before resorting to the acid; in *only one* was perfect relief afforded. The vomiting has been so severe in the prevailing epidemic, that it would seem as if the stomach was unable to bear so nauseous a mixture as that of chalk and opium. And in most of the cases I have found the best, indeed the only efficacious plan to be, to relieve the intense gastric irritation by cold water, before resorting to the medical treatment. In some cases, if the stomach will bear it, the chalk seems to stop the diarrhoea, but to increase the nausea, and produce most uncomfortable sensations in the bowels on the day after its exhibition. This I have invariably observed in the olden plan of treatment.

The conclusions to be drawn from my experience of the sulphuric acid in the treatment of diarrhoea and dysentery, are as follows:—

1st. It is *more efficacious* than alkalies, opiates, and astringents, in a proportion greatly exceeding ten to one.

2nd. It is *more rapid* in its action, (especially in children,) in a proportion greatly exceeding twenty to one.

3rd. It seems to act in a more rational and (if I may so express myself) scientific manner, by increasing the *tone* of the mucous membrane of the alimentary canal, rather than by simply astringing its pores.

4th. The worse the case, the more rapid and marvellous seems to be the cure,—a most striking feature as compared with the treatment by chalk and opium.

I would urge, in conclusion, upon my medical brethren, the desirableness of giving this system a fair trial; and I would, moreover, advise them, instead of giving the acid alone, with water, to combine it with a little sugar and (most rare and excellent of all tinctures,) compound tincture of cardamoms, which seem greatly to relieve the so-frequent distressing flatulence. Unless the character of this autumnal epidemic should greatly alter, they will arrive at the conclusion, after having tested fairly the acid plan of treatment, that it does not

admit of comparison, but only of *contrast*, with the olden system.

P.S. Since writing the above I have seen one case in which the acid failed. Chalk and opium carried the day.

Enfield, September 2, 1852.

CASE OF CANCER OF THE PYLORUS

UNDETECTED DURING LIFE.

By ANDREW PAUL, Esq., B.A., M.B., OXFORD.

To the Editor of the *Medical and Surgical Journal*.

SIR,—Your journal is not what it ought to be—a copious record of provincial medicine and surgery. Save from “smoky Birmingham” and “fair Leicester,” we have few, if any, cases recorded from our hospitals and infirmaries in the provinces. This is not as it should be. Surgeons like myself, “unattached,” meet with cases, valuable because instructive. We see them, as here, prior to admission, and, I am sorry to add, we see them when in despair they leave the hospital, as they say, to “die at home.” Without further preface, I rush at once in *medias res*, endeavouring, as far as I can, to give to the succeeding case, its history from the alpha of my acquaintance with it, two years ago, down to its omega in the *post-mortem*, conducted by myself, on Friday last, twenty-four hours after death.

I am, Sir, your obedient Servant,

(And a six months' Associate,)

A. PAUL.

Oxford, August 12, 1852.

John Higginson, aged 47, married, two years ago came under treatment for epigastric pain, flatulence, and costiveness. Complexion sallow; eyes dark, and unusually lustrous; conjunctiva and cornea of that pearly whiteness so familiar to us in consumption; has inguinal, omental, and ventral rupture on the right side. At this time I thought much of his pain was owing to the pull upon the stomach, as a volume of omentum was constantly in the sac. He had some aperient medicine, and I saw him, off and on, up to February last, when he was fairly brought to a stand still. I found him with obstinate vomiting; tympanitic abdomen; “gnawing clawing” pain in epigastric, right and left hypochondriac regions, with a sense of “balls rising up and down in his belly.” I cupped and blistered him. He had been salivated five years ago for the liver. I went through a *regiment* of stomachic opiates, creasote, bismuth, opium, oxyde of silver, hyoseyamus, conium, prussic acid, and chloroform, in vain. The only drug I found to give the longest relief, was the extract of *rumex aquatica*. This herb, if known to, is not prescribed by, the profession; it is powerfully astringent as to incised wounds. In operations,

for instance, where the skin is sacrificed, its powers of hastening cicatrization beat everything I know of. The salivated sore mouth it rapidly cures. Amongst water-weeds we have an abundance of the rumex; in stagnant pools, adjacent to the classic Isis and its tributary the Cherwell.

J. Higginson's employer made him an in-patient under Dr. Jackson, in the Radcliffe Infirmary, who treated him "for the liver." His case was watched by Mr. Briscoe, the house-surgeon. Lunar caustic and opium stopped the vomiting. After six weeks' sojourn, and getting no better, he left, as he said, to die at home. The first week in June I found him all over dropsical; appetite gone; skin of a tallowy whiteness; pain at night incessant; features drawn, haggard, and expressive of intense inward suffering. Twenty-four hours before death he had the usual coffee-grounds vomiting.

Post-mortem examination.—Abdominal parietes unusually thin; a gallon of water in the abdomen, straw-coloured, coagulable by heat, by the red and yellow prussiates of potash, by nitric acid, creasote, and by galvanism. No effect on turmeric. Peritoneal surface of the bowels normal; kidneys and liver healthy; gall-bladder filled with bile; omentum drawn down, and found in the right inguinal ring; on turning up the liver, a solid tumour (a congeries rather of tumours) presented, surrounding the pylorus; and on raising the stomach, the pyloric end, held by slight adhesions, gave way, exposing an opening the size of an orange, revealing, in short, cancerous ulceration; on removing the stomach, and dissecting through the lesser omentum, I came upon a second mass, the size of my fist, the same as the other, resting upon the pancreas, the aorta, cava, and thoracic duct, and firmly adherent to the spine; the reflections of the peritoneum formed the outer covering; two mesenteric glands (enlarged,) partook of the disease. A section of these masses resembles that of brain, and once or twice steeped in alum and nitre, they resemble, in colour and consistence, the atheromatous tumours we frequently remove from off the scalp of elderly people. No chronic peritonitis. Disease of his heart he told me he was thought to have in the infirmary; this I did not look after, satisfied that what disease he had was altogether in the abdomen.

Now, this man from time to time has been under the *élite* of Oxford, (medical and surgical,) Messrs. Acland, Jackson, Wood, Simmonds, Godfrey, Briscoe, and, lastly, your humble servant, all of us have had a turn at the liver, for disease thereof, and all of us, as the sequel proves, were mistaken. Will some one of your readers help us to a diagnosis?

This man had been salivated five years ago for *soi disant* hepatitis; the *real* complaint was then, I have no doubt, in its infancy. So closely do these tumours resemble tubercle in the lungs ere softening down in ulcerative phthisis, that mercury, as in the one it is, so also in the other must it be, *poison*. We find, in short, that cancer, scrofula, and phthisis, are members of but one and the same family.

Should this case be worth insertion, I may, occasionally, trouble you with cases, and put questions to your readers, consequent upon my want of success in treatment—a want which has befallen other and mightier constellations than myself, who am but a nebula in our professional firmament—a fact which, nevertheless, does not console me for my bad luck, though compelled to move in the same orb. *Palmar qui meruit ferat.*

[Although Mr. Paul may have erred in his diagnosis, we do not see how he could have treated the case better, had he known before death the precise condition of the internal organs. We do not understand how the remedies used, either by Mr. Paul or Mr. Briscoe, could have been expected to relieve hepatitis in any form; and the only proof adduced by Mr. Paul that the disease was at any time mistaken, consists in the salivation five years before death. But we suppose Mr. Paul must have had the evidence of Messrs. Acland, Jackson, &c., as to their errors of judgment, or he would not so broadly state the fact; at all events it is curious that, with an error in diagnosis, there should coexist the proper treatment for an undetected disease.—ED. J.]

Hospital Reports.

WEST NORFOLK AND LYNN HOSPITAL.

CASES ADMITTED UNDER THE CARE OF CHARLES COTTON, M.D., F.R.C.S., SENIOR SURGEON TO THE HOSPITAL.*

Stone in the Bladder—Lithotomy—Subsequent Hemorrhage on fourth day—Death.

WILLIAM JARY, aged 35 years, labourer, admitted May 19, 1849. Has suffered during the last several months from the usual symptoms of stone in the bladder. Complains most of frequent and painful micturition, and a considerable degree of weight and uneasiness referred to the region of the bladder. The urine comes away in small quantities, and is occasionally mixed with blood. The patient, though a fine hale looking man, is in a low desponding state at the prospect of an operation, which he is sure he cannot survive; it subsequently appeared that he was so impressed with the inevitable fatal termination of his case, that previous to entering the hospital he had already selected a spot for his burial place. A moderate-sized calculus detected on sounding. Ordered a mixture of nitre, soda, potass, and henbane, and any reasonable indulgence as to diet or liberty with a view to allay bladder irritation and secure mental composure.

June th.—Consultation. Lithotomy determined upon. A few days since lithotritry was proposed and about to be practised, when the patient insisted upon being only cut.

11th.—The usual perineal section made, and a rough, oval, flattened lithate of ammonia calculus removed.

The operation considered very successful. An elastic tube having been introduced into the bladder and secured, the patient was placed in bed exposed to the air to check a disposition to bleeding. Other operations being ended, the patient was again visited, when rather a free, arterial-like hæmorrhage rendered it necessary to plug the wound. This was done by passing lint around the tube in lieu of withdrawing it, in effecting which, the probe by some accident slipped and pierced the rectum.

12th.—Quite comfortable. Urine, tinged with blood, passes freely through the tube.

13th.—Going on well.

14th.—In excellent spirits, complaining a little only of uneasiness about the wound. Urine somewhat purulent and offensive. The elastic tube and plugs withdrawn.

15th.—In answer to an urgent summons was visited at 9 A.M., by Mr. Cotton. Found insensible; skin blanched; pulse and breathing scarcely perceptible. The night-nurse steadfastly declaring that no bleeding had occurred, but that the patient was taken suddenly ill early in the morning, after straining to make water naturally, but as he afterwards fell asleep, she did not see occasion to disturb the House-Surgeon until a short time ago, when she felt alarmed. Messages were immediately dispatched to warn the friends of the sudden and mysterious change in the state of the patient, and every possible attempt made to promote reanimation, at first with some little encouragement, the pulse becoming just perceptible at the wrist and respiration less feeble; but ultimately death took place late in the evening, after a protracted stage of extreme collapse and exhaustion.

Post-mortem examination.—The parts about the seat of operation showed a sloughy disposition and signs of recent hæmorrhage. On carefully cleansing the wound, and removing a pellet of fæcal matter which protruded, a small oval opening, nearly the size of a fourpenny piece, was observed, leading into the rectum; and on continuing the examination, the mouth of a vessel to the left side of the wound was discovered, which, on dissection, was traced to its origin from the pudic, and proved to be the superficial perineal artery, larger than usual, proceeding across the perineum towards the mesial line, and directly in the way of the incision for lithotomy. The bladder was found contracted and empty, with its coats corrugated and thickened, as if from long irritation. The other parts of the body were in a healthy condition.

At the conclusion of the inspection a further searching inquiry was immediately made, when one of the patients charged the night nurse with concealing the cause of the man's death, adding that he had seen her carry away large quantities of clotted blood and bloody linen, after the man had been straining and become worse. This statement led to a confession on the part of the nurse that her attention had been only called to the patient on finding him speechless, faint, and yawning, when she was frightened at observing a large quantity of blood in the bed, which she removed,

hoping the patient would rally, and the matter escape detection.

The annoyance of failure in the midst of hope and presumed safety, from secondary hæmorrhage—a rare occurrence—was rendered still more vexatious in this case, owing to a determination on the part of the friends to commence legal proceedings against the resident authorities of the hospital for negligence; and such further disagreeableness was only, after some difficulty, prevented, on the operator assuring the parties that the fatal hæmorrhage was entirely accidental, and that he alone was to blame, inasmuch as had he withdrawn the tube in the first instance, and secured the bleeding vessel by a ligature, rather than trusted to pressure, the sad event, in all probability, would not have happened.

[To be continued.]

Proceedings of Societies.

BATH AND BRISTOL BRANCH.

A MEETING of the Local Council was held at the Bath United Hospital, on September 3rd, 1852, "To consider if any or what steps shall be taken by this Branch, to support the resolution relating to the *Journal*, passed at the Oxford meeting." George Norman, Esq., in the chair. Present,—Dr. W. Budd, Messrs. Clark, Colthurst, Morgan, Pichard, Smerdon, of Bristol; Dr. Davies, Messrs. Bartrum, Ormond, Soden, of Bath; Mr. Adye, of Bradford, Mr. Crang, of Timsbury; and Mr. Ogilvie, Ridgway House.

The Secretary of the Association attended the meeting, and read a statement of the proceedings at Worcester, relative to Dr. Cowan's notice of motion, also a written statement of the President of the Central Council, as well as the minutes of the Central Council on the subject of the *Journal*. It was moved by Dr. W. BUDD, seconded by Mr. J. SODEN, and unanimously resolved,—“That this Council, after having heard the correspondence, including the minutes of the Central Council, as read by the Secretary of the Association, is of opinion, that, notwithstanding certain informalities occurred in putting the resolutions, touching the future conduct of the *Journal* to the Oxford meeting, yet as no objection was made at the time to the course of the proceedings, these resolutions must be considered as past and binding on the Association.”

It was moved by Dr. DAVIES, seconded by Mr. ORMOND, and resolved unanimously,—“That in the opinion of this Council, the objection taken by the Central Council, to the notice given by Dr. Cowan, with reference to the alteration of the *Journal*, is untenable, because that notice was adopted by the Central Council, and circulated by them to the members of the General Council, and was adopted and acted on by the meeting at Oxford as legal and regular.”

It was moved by Dr. BUDD, seconded by Mr. CLARK, and resolved unanimously,—“That the Bath Secretary

be requested to forward a copy of the above resolutions to the Secretary of the Association, and another copy to the Editor of the *Journal*, for publication in the *next number of the Journal*."

It was moved by Mr. ORMOND, seconded by Mr. PRICHARD, and resolved unanimously,—“That the best thanks of this meeting be given to Mr. Sheppard, for his attendance here to-day, and for his courteous conduct to the members now assembled.”

JOHN S. BARTRUM, Hon. Sec.

SOUTH WALES BRANCH.

THE first meeting of the MONMOUTHSHIRE AND SOUTH WALES BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION was held in the theatre of the Royal Institution, Swansea, on Thursday, the 26th of August. Dr. G. G. BIRD, of Swansea, President.

At two P.M., the members of the Society assembled, and the following gentlemen were present:—Sir C. Hastings, M.D., D.C.L., James P. Sheppard, Esq., Secretary to the Provincial Medical and Surgical Association, Worcester; Trevor Morris, M.D., Chepstow; C. R. Vnchell, M.D., Cardiff; Charles Sylvester, M.D., Cowbridge; W. T. Edwards, M.D., Cardiff; Mr. H. L. Prichard, Margam; Mr. Nathaniel Coates, Sirhowy Iron Works; — Stark, M.D., Newport; Mr. George Cherry, Caerleon; Mr. John Williams, Pontypool; Mr. W. W. Morgan, Newport; Mr. James Probert, Plymouth Iron Works, Merthyr; Mr. F. J. Dyke, Albert Street, Merthyr; Mr. J. Bowen, Carmarthen; Mr. E. J. Steele, Abergavenny; Mr. J. Jones, Amman Iron Works; Mr. F. M. Russell, Cwmavon; D. J. Whitty, M.D., Briton Ferry; Mr. French, Mayor of Neath; Mr. W. G. Jones, Neath; Mr. William Price, Glan Twrch; Mr. Cook, Morriston; Edward Howell, M.D., Swansea; G. G. Bird, M.D., Swansea; Mr. W. Rowland, Swansea; Mr. H. Long, Swansea; Mr. J. E. Hall, Swansea; Mr. W. P. Evans, Swansea; Mr. T. A. Essery, Swansea; Mr. W. H. Michael, Swansea; Mr. Tindal Robeston, Swansea; Mr. R. V. Leach, Vernon House, Briton Ferry; &c. &c.

A little after the hour above named, Dr. Bird proceeded to read the following Address:—

Gentlemen,—It was remarked by one of the most eminent surgeons of the present day, “that the medical profession was a noble profession, but a very low trade.” I have no doubt that this observation arose out of perfect conviction of the truth on the part of the distinguished speaker; and I think a little reflection would make it plain to any, that to practise our art solely for a livelihood, or for mere gain, is not the only duty involved; it must be perceived that a man owes more than this to himself, more than this to his profession, more than this to his professional brethren, more than this to mankind, and surely more than this to the Divine Being who gave him existence, and reason, and thought, and hope, and endowed him with improveable faculties and affections, all for some ends truly—cer-

tainly not for mere selfish ends only. Hence, gentlemen, it is not surprising that we should, as a body, desire to meet together for the purposes of doing good to each other, and for the advantage also of our fellow men—for our own mutual advantage and for theirs, and in order to support and encourage and assist each other, on the right pathway of wisdom, truth, and duty; and this, I take it, is the reason we have met together; and this, as I understand it, is the object of the Provincial Medical and Surgical Association of England and Wales.

It is now twenty years since the Provincial Medical and Surgical Association saw its first meeting; and I venture to believe the consequent results have fully borne out the benevolent aspirations and hopes which its eminent founder, and those who were intimately associated with him in his early labours for its formation, at that time conceived.

Doubtless, amongst the various causes that have, within the period of time of which I have just spoken, severally contributed to the honour, advantage, and usefulness of our profession, it may be truly stated that this Society, in many respects, has stood pre-eminent in the van; originating in the spirit of usefulness, having for its object only good, and steadily progressing with continually-acquiring power, both in numbers and effect, until at this time we may behold it by no means one of the least influential societies in any profession, having already accomplished much good, both to the medical and the general public, and, as we hope, steadily devoted to accomplish further good.

There are many around me, whom I have the honour now to address, who remember the surface of our profession, which we may well love, considering its tendencies and objects, displaying a far less desirable appearance than at present, whilst intrinsically there is, doubtless, a vast improvement in the feelings and tone of the general body and its different grades, towards each other, and a better unity of wish and action for the advantage of its members, and the good of society at large.

I think whoever shall rightly consider the aim and objects of medicine and surgery can only come to one conclusion, namely, that their province is, under the direction and guidance of a kind merciful Providence, the good of mankind.

This axiom may, I think, in some measure be illustrated by the fact that the truly wise and good men of our profession have, in all ages, untiringly devoted their zeal and best energies to this truly philanthropical object, and have accordingly spent their lives in doing good to their fellow-men, and in improving the science to which they had devoted themselves.

I humbly conceive that my proposition is yet more fully borne out by the just consideration of another fact of a solemn and portentous character, showing the unselfish nature of our profession, namely, that it appears by the statistics of the duration of human life, that in our calling there are fewer aged men than in most, and that in few civil occupations is the average duration of life so brief as amongst the practitioners of medicine and surgery.

This well-ascertained truth, brings with it home to

the mind many considerations replete with deep thought and appropriate reflection, standing widely apart from, although rising out of, the abstract fact, that the nature of our daily duties, our constantly interrupted repose, our broken leisure, our uncertain and often scanty periods of rest and refreshment, our labours, anxieties, constant care for others, and our heavy professional responsibilities, together with the melancholy and painful scenes we continually witness, and are called upon to sympathise with, are all of a nature to depress the powers of life, and that they necessarily tend to shorten our existence, and this far more than is usually the case with the generality of the more peaceable of human occupations.

I say there are other considerations—many others, naturally arising out of the primary one, some replete with solemn and portentous warning for the future; some which point at the sound wisdom and cautious policy of this world, and others again, if we act in a right spirit, by no means devoid of consolation and hope, but in some respects, if rightly viewed, were well calculated, I think, far to outweigh the mere consideration of the brevity of life, to which we are more or less especially liable, for one true mode of computing time is not by its mere duration, but by the use which is made of it, and the good purposes to which it is devoted; and viewed in this light, and acted on in this spirit, medicine may be said to be the handmaid of true religion, the offspring of charity, piety, and benevolence, which are all, as we truly know, the gifts of God, and under His guidance a healing balm to the suffering children of the family of man.

I trust, I may not in your estimation have gone further than I should have done in glancing at the practice of our art in the view wherein I have ventured by these few remarks to place it; for, doubtless, such considerations must and do frequently occupy our thoughts and reflections, and therefore may, I hope, be alluded to without impropriety here.

I shall take leave to observe further, that it seems to me the important fact of the brevity of life in the medical profession is a subject, however, that should with much propriety and advantage occupy the consideration of its members, as a community, with a view to lessen the average mortality amongst them, in so far as it can be legitimately accomplished; and I apprehend this desideratum is, in a comparative measure, almost as important to the public as it is to ourselves, and those who, by various ties of relationship, are connected with us; for it must be remembered that by no means the least considerable attribute of professional usefulness, competency, and excellence in medical men, in addition to a sound education, is medical and surgical experience acquired by a long course of habit and observation, and an intimate acquaintance with disease and its treatment, together with practical opportunity of clinical acquirement, and this, to produce its due effect, can only be attained by degrees, and through the accretion of time and opportunity; certainly, therefore, when men possessed of these attributes are frequently and successively removed by death from amongst us, in the prime of maturity and middle life, it may be said

to be a great public loss; and I may adduce to my professional brethren whom I now have the honour to address, an instance with which they are well acquainted, viz.—the striking fact that in the metropolitan portion of our profession, within the last very few years, a galaxy of professional talent of the highest order, and an amount of skill and experience, the loss of which has been deeply felt and deplored both by the profession and the public, and will not be easily replaced, has passed away—prematurely cut off by the hand of death. I may amongst those mention the revered names, dear to many, by the ties of pupilage and reminiscences, of Aston Key, Henry Earle, Liston, Tyrel, Dalrymple, with many others, who have thus early died, but died at their posts, and fell at the shrine of professional zeal and usefulness.

And if so it must be, may we ever have many amongst us, even to the end of time, ready so to live, ready so to die, and prepared to die and to leave their honoured names and history to posterity as bright beacons to light the pathway of future generations, and examples to follow on the road of zeal, truth, and duty.

I have ventured to say I thought it a subject for deep consideration how far the average mortality amongst our community could be lessened, and I have generally glanced at some of those causes which have a tendency to depress the powers of life and shorten existence; and no doubt it is so. I have, within the last thirty years personally known many of our profession in the Principality, now no more; some of them my intimate friends; many of them I have seen during the course of their illness, and some I have attended to the last. Of these very few indeed attained the age of 60 years, and fewer still an age much beyond it. I may further remark that in a list consisting of thirty-one individuals of the medical profession resident in Monmouthshire and South Wales, all personally known to myself, who died during the last 30 years, I find that their ages united gave an aggregate of about 1395 years, or to each individual 45 years as the average duration of life; of these many died far younger, and some, I feel assured, from the want of care and medical remedies sufficiently early in their illness; they worked on in spite of warning and illness, till it was too late. Others I know, overtaxed their strength, and broke down, I have only in this statement alluded to gentlemen who were personally known to me; for I do not think this list contains a third of the deaths of medical men that have occurred within this time in the districts alluded to. But I think it shows the necessity for care and the advantage of mutual assistance and brotherly feeling for our mutual protection and safety. Whilst speaking of the duration of life, I desire to say a word on life-assurance, a subject not more important to any than to our profession, for this often constitutes the only means by which we can hope to leave provision for our families, as the few remarks I have made significantly show, for in a short life, accumulation of property arising out of business cannot be a matter of every day occurrence, and hence especially the stability of insurance offices is a matter to us of the highest moment.

Through the kindness of a friend I have procured the following statement, and it carries with it good and timely caution :—

It appears that in Great Britain the amount covered by insurance—in life-assurance offices—is upwards of 150 millions sterling; the annual premiums paid, 5 millions. The offices are in number, 152 in England, and 15 in Scotland. The amount assured in Scotland is about 34 millions, and in England 116 millions. Since the year 1841, there have been 141 new offices projected, and 131 founded; 78 have ceased to exist, 3 have amalgamated, 20 have transferred their business, and 6 are winding up in Chancery. 75, or nearly one-half of the existing offices, have come into operation since 1844—the year of the Joint-Stock Regulation Act, which, my friend observes, he fears has offered, unless great caution be used, very dangerous facilities for the manufacture of such societies. It seems to me, I repeat, that this information carries with it a lesson of prudent selection, and this is the reason I have ventured to adduce it here.

I proceed to say, that so far as my own observation has gone, in reference to the early death of medical men, and of course it only relates to provincial practitioners, I believe part of the evil tending to shorten existence often arises from want of due caution and care in the earlier periods of life, disregard to proper protection against weather, or changes of attire, and sitting in damp clothes for hours, a total disregard as to regularity of meals and due repose, and oftentimes the want of such systematic arrangements in carrying on their business as lie in their power, and would in a measure secure important advantages; these also are all, for the most part, sure harbingers of future illness, for they gradually depress the vital powers as a whole, and render the frame accessible to disease. It is a true axiom, that “where resistance ends, disease begins.”

Again, looking at the vicissitudes of practice, sudden calls for professional aid at late hours, after the ordinary business of the day in general life may be considered over, and unceasing interruptions during the hours of meals, both no doubt greatly detrimental to continued health, especially if taken in conjunction with other causes; for it is seldom to one cause only that illness may be attributed, but to a combination of causes, so much so that hence has arisen the medical aphorism, “One cause alone sufficeth not to produce disease.” One of the causes last alluded to, it appears to me, might, by better regulations and better understanding between the public and the profession, be very much ameliorated, especially by setting aside a certain part of the day, and, as far as possible, scrupulously and habitually abiding thereto, for seeing patients at home, where the public would be encouraged by experience to know that, unavoidable emergencies excepted, we should certainly be found in the way; as it is, in country practice, people flock to medical men’s houses about the usual meal times, because, to use a common expression, they “are likely to catch them at home”—another word for surely interrupting them at meal times. Our professional brethren in the metropolis and

large towns are, to a great extent, wiser in their generation than we are, for they set their faces against this as much as they can, and I think they are right. They have, it is true, better opportunity for so doing; but I am of opinion country practitioners might, with great advantage to the public and themselves, do this to a much greater extent than they are in the habit of doing.

With regard to calls to visit patients at late hours, I think if any practitioner will sit down and reflect, he will perceive that out of these calls, whether late in the evening, or later still—after having retired to rest, not one in three arises out of real emergency, truly so called, or from sudden illness, but from a postponement of sending for advice until peremptory alarm for safety, or the continued vicissitudes of pain and suffering, admitted of no further delay, a very common expression being, “I was very ill all day, but I waited till the evening, to see if I should be better;” and in moderately extensive practice it is, as my hearers are all well aware, not uncommon to be solicited to visit three or four such cases after night, probably involving a ride of several miles, which might have been easily obviated, with advantage to all, by more timely, wise, and considerate determinations. Much of this rather serious evil might, I think, be done away with by proper and temperate explanations, given in good faith, and taken in good part, supported, if necessary, by a perfectly just and moderate claim for adequate remuneration, excepting in cases of real emergency, to the calls of which, heaven forbid, we should not all cheerfully and readily respond, whether for reward or without reward, in so far as we are able. I venture to think the profession would do well, as a body, to take this subject into consideration, and be acting as wisely for the public as for themselves in endeavouring to lessen the amount of wear and tear in professional life which the practice I have adverted to oftentimes very unnecessarily entails on its members. For that consideration to which a man is in justice entitled, he may clearly, with propriety and fairness, seek and expect; and it is not too much to expect from any, that he should do as he would be done by. Certainly, by all reasonable means and just proceedings, if we cannot do all we would, we may justly do what we legitimately may, to use a phrase of the day, in order to ameliorate the condition of the working classes, of which, I think, we form a very exemplary part.

Another rather serious evil, gentlemen, forming frequently a source of much inconvenience and danger, to which I briefly advert, for it is one replete with anxiety, and adds greatly to our responsibilities and cares, oftentimes is in country districts the want of competent and intelligent nurses to attend the sick; the remedy of this rests as much with the public as ourselves, but I apprehend the evil is frequently felt, and may admit of a gradual remedy, without great difficulty, and without injuring the interests of any.

I have said nothing, gentlemen, of intemperance as one of the evils, not only tending to shorten, but certainly lessening the duration of life; happily this can

never be a general vice in medical life, for to be given to this is only another word for certain ruin, and for my own part I never witnessed an exception to the rule. I have not known a successful drunken medical practitioner.

I must crave your patience, gentlemen, for one moment longer. I venture respectfully to observe there is yet one evil to which we are exposed—one which we cannot altogether remedy, but yet which we ought to avoid as much as possible—and that is, using the Sabbath day more than can possibly be avoided for our business purposes. The seventh part of the life of a man has been deliberately and specially ordained and consecrated by the wise Disposer of events for the purposes of devotion, reflection, and rest; and it seems to me impossible that this portion of time can be employed after the manner of ordinary days, without entailing, amongst other evils, the natural effects of this additional amount of "wear and tear," for to argue otherwise would be clearly to assert the *ad absurdum* that the greater is equal to the lesser. I shall not advert to this subject further, seeing that this is not the appropriate place for delivering a sermon on religion, although I am happy and proud to believe there is no lack of religion, piety, faith, hope, and charity, in the members of our profession.

Gentlemen, I have endeavoured to place before you some points connected with the every-day life of our profession, which I ventured to believe might, without impropriety, be deemed worthy of your consideration; and in connexion with the same subject permit me to add, that no one thing can, in my humble judgment, promote the advantage of all more than the well-weighed and well-directed efforts of all, to one common end—the good of all; and hence I infer, that societies like our own, if well managed and duly supported, are eminently calculated to be productive of substantial benefits, for by these means, what is beneficial will be likely to be suggested, where it will meet with adequate support and approbation; what is otherwise will be discouraged with effect, and that which is determined on will find a power ready to aid matured decision equal to the accomplishment of the end in view. All these are great and necessary elements in success. By such societies opportunity to know each other, and that knowledge of each other, which eventually leads us to confide in each other, are afforded, and this spreads like leaven through the whole community of the profession, and promotes unity of aim and purpose. Certainly, in one respect, opportunity is necessarily the parent of confidence—a child of slow growth; for, without sure knowledge of safety, who, being rational and wise, can venture to confide?

I apprehend, gentlemen, and I say so emphatically, that in an important and numerous profession like our own, small legislations are like small warfares, seldom leading to real advantage; for selfish aims, calculated only to benefit a few, a class, or a grade, are generally viewed by the many as odious in their nature, and are usually pernicious in their results, promoting angry rivalry, disunion, envy, and hate; and wherever these

undesirable feelings of our nature are engendered, and especially where excuse for their display exists, let them arise where they may, they do not commonly rest only with the originators, but spread like a plague-spot and a poison, until no place or persons are left, amongst whom the contamination has not found its way, and thus probably a habit of angry discussion and cavilling and wrangling spirit are fostered and engendered, so that an animadverting and suspicious disposition and tone become the prevailing vice of the time. I apprehend it was out of such a prevailing spirit in the medical men of their era, that Le Sage and Moliere found food for satire and ridicule at the expense of the medical profession, which amused society nearly for a century, and made the "quarrels of medical men" a by-word for small revilings, vulgar bitterness of spirit, and undignified quarrels.

It has been, gentlemen, I believe, through the Provincial Medical and Surgical Association, in a full measure and degree, amongst other causes, that the medical profession of our day in this country is rapidly assuming a far different phase;—through it, in a great degree, that we are better known to each other and to the world at large; I hope, as a body of men earnest in effecting good and improving their knowledge, having no selfish objects of their own to gratify or seek at the expense of others,—moderate and just, as I trust, in their expectations, and contented with their lot in life, kind and united amongst themselves, and kindly and well-disposed to all. Indeed, gentlemen, in the latter aspect I may say, without departure from truth, although I say it not boastfully, but I say it with honest pride, that to no profession is the public, and especially the needy portion of society, more indebted for eleemosynary labour and unrequited exertion, than to ours, and in none is the ear of pity and compassion more open to the tale of woe, oppression, or distress; and so far, at least I think, we may all hope our community is not far from the right road.

I will not, gentlemen, detain you longer at this time, for we have much to do, and I feel assured it will be done well, and in a good and brotherly spirit; that hence we may know each other, and trust each other, and act with each other for the common good of all, and to the injury of none;—that what is good, will at your hands meet with aid and encouragement: what is evil, with discouragement and proper reproof;—that the motto of our Society may consist in the benevolent aspiration of the great apostle and servant of Christianity, St. Paul, "Let brotherly love prevail," and in the divine injunction of our Saviour, "This commandment I give to you, that he love one another."

The address was throughout received with demonstrations of approbation, and its termination was signalled by enthusiastic applause.

Dr. BIRD then said, that all present were perfectly aware that he occupied that chair only temporarily. Several friends had met together to consider the propriety of forming this Society, and when they had consulted with others, they had, as it was necessary to have organisation of some kind, made their arrangements

provisionally, till the medical men of Monmouthshire and South Wales could be called together, to give the Society a permanent form and constitution. Under these arrangements he (Dr. Bird) had been appointed President, and his friend Mr. Michael, to whose activity this Society owed so much, was appointed Secretary. This being the first meeting of the Society, the duties of the provisional officers would terminate, and it became necessary to appoint others in their room; and from among them, before they proceeded to business, they would first select a President of this meeting. Dr. Bird concluded his observations by congratulating the meeting on their success, attested by the fact, that it had already enrolled seventy-five members of the profession in Monmouthshire and South Wales. (Applause.)

Dr. Bird having vacated the chair, it was proposed by Mr. MICHAEL, seconded by Mr. ROWLAND, and carried unanimously, "That Dr. Bird do preside at this meeting."

THE PRESIDENT then called upon Dr. MORRIS, who said that he had the honour to propose the first resolution, and if that resolution required observations to recommend it to the meeting, he should have felt his incompetency for the duty which now devolved upon him. It did not so, as he believed opinion was unanimous upon it. Dr. Morris then proposed that "The Monmouthshire and South-Wales Branch of the Provincial Medical and Surgical Association be now formed."

The motion having been seconded by Mr. ROWLAND, was put from the chair and carried unanimously.

Dr. HOWELL then rose to move the second resolution, "That Dr. G. Gwynne Bird be the President for the year 1852-3." This resolution having been seconded by Mr. Brewer, was put to the meeting, and carried unanimously.

Dr. BIRD, in briefly acknowledging the honour conferred upon him, observed that it should be his constant endeavour and ambition to promote the objects of the Society. He was fully conscious that from among his medical brethren a more competent selection might have been made; but as far as lay in his power, he should endeavour to meet the duties which, as President, devolved upon him. It was not one of the least pleasing features in their selection of him as President, that he had been proposed by his friend Dr. Howell; at the same time with whom he entered upon professional life twenty-six years ago. He believed that a man of better heart could not be found; he was at once a kind friend and an excellent practitioner.

Dr. VACHELL moved, and Mr. Rowland seconded the next resolution, "That the meeting of 1853 be held at Chepstow, and that Dr. Morris be the President-Elect." The resolution having been duly carried,

Dr. MORRIS, in returning thanks for the honour conferred upon him, said that he should shrink from the acceptance of the responsibilities which it implied, if he did not rely on the kindness and support of his medical brethren. He took the opportunity of assuring the Society that he should receive them with a brother's love, and that no effort should be wanting on his part to render the Chepstow meeting one of interest and

instruction to all who would honour it by their presence.

The Secretary, Mr. MICHAEL, then read the

Report of the Provisional Committee.

"The Council having long felt desirous to place prominently before the profession in the Principality the claims of the Provincial Medical and Surgical Association to its support. The want of a bond of union and a rallying point, around which should centre the better feelings and kindlier emotions of the too often estrayed member of a common profession, has long existed, and has been universally acknowledged and lamented.

"These circumstances determined your President, in accordance with the wish of Sir Charles Hastings, President of the Council of the Provincial Medical and Surgical Association, and at the request of many members of the medical profession residing in South Wales, in calling together a few gentlemen from various parts of the Principality to ask their advice and to hear their opinions as to the advisability of establishing a Branch Association which should comprehend within itself the medical practitioners of Monmouthshire and South Wales.

"Such meeting was called on the 10th of March, and fifteen gentlemen attended, when it was unanimously resolved,—

"That it being in the opinion of this meeting desirable to form a Monmouthshire and South Wales Branch of the Provincial Medical and Surgical Association, a meeting be held at Swansea, on Wednesday, August the 25th, to take such steps as may be deemed necessary for the attainment of the object; that G. G. Bird, M.D., be this day elected Provisional President, and that he be desired to preside at such meeting, and also to read an address on the occasion."

"A Provisional Committee was likewise appointed to take such steps as might seem to them necessary to the attainment of this object, to make the necessary arrangements for holding the meeting at Swansea, to obtain members, and to prepare such laws for the future guidance of the branch as might seem to them desirable:

"In accordance with these resolutions, your Committee now resign into your hands the self-imposed offices, and we are happy in being able, at the same time, to announce that seventy-five qualified members of the profession have joined the Branch Association, which bids fair to be one of the most important and flourishing of those already belonging to the Parent Society.

"Your Committee trust it may long continue to increase in usefulness and extent, and that this may be the first of many pleasant annual gatherings, not altogether without effect in aiding the members in their daily avocations by augmenting their knowledge, and drawing closer the ties of good fellowship and social intercourse.

"Your Committee rejoice in the establishment of such a Society in the Principality, as serving to afford opportunities of meeting old friends whom the exigencies of life have long separated, and in increasing the number of those who should be known to each other as united in one common brotherhood, whose purpose of life and their highest honour it is to be ever engaged in the mitigation of suffering and the alleviation of distress."

On the motion of Dr. EDWARDS, seconded by Dr. HOWELL, the reception and adoption of the report was confirmed by the meeting.

On the motion of Mr. ROWLAND, seconded by Mr. STEELE, it was unanimously determined that the following gentlemen be the officers of the Branch for the ensuing year:—

"Council.—Dr. Howell, Swansea; J. Brewer, Newport; E. Davies, Merthyr; Dr. Lawrence, Carmarthen; J. D. Brown, Haverfordwest; Dr. Vachell, Cardiff; E. Evans, Cardiff; W. P. Evans, Swansea; Dr. Davies, Brecon; F. C. Batt, Abergavenny; Dr. Sylvester, Cowbridge; Dr. Price, Monmouth; J. French, Neath; J. L. White, Dowlais. *Secretary*.—W. H. Michael, Swansea."

The Secretary then read over the rules and bye-laws of the Society, prepared by the Provisional Committee; they were subsequently submitted for discussion *seriatim*. Some slight amendments were made at the suggestion of various members. These amendments, for the most part, referred to extension of times of notice in calling meetings, and to the number of members forming a quorum in committee meetings. When the whole body of rules and bye-laws had been thus deliberated upon, their adoption as amended was confirmed by the meeting, on the motion of Mr. H. L. PRICHARD, seconded by Mr. PROBERT; as was also a resolution moved by Mr. E. EVANS, seconded by Mr. STEELE, to the effect that the *conversazione* in connection with the Medico-Ethical Association be held in Cardiff.

Dr. MORRIS then moved a resolution expressive of the regret of the meeting at the contemplated removal of the *Provincial Medical and Surgical Journal* from Worcester to London—a step which the resolution characterised "as endangering the fundamental principles of the Institution, and the law on which it was based by its first founders." The subject called forth remarks from the President and several other gentlemen, all disapproving of the removal. The resolution having been seconded, was carried unanimously, as was also another resolution expressive of the desirability of an organ of provincial medical practitioners being published and edited in a provincial town.

The thanks of the meeting were then duly given to the Mayor of Swansea, for placing the Guildhall and Assembly Rooms at the disposal of the Committee; and to the Council of the Royal Institution of South Wales for the use of the theatre.

Mr. E. EVANS then moved, "That the thanks of the meeting be given to Mr. Michael, for his able services as Secretary, requesting him at the same time to continue his services as permanent Secretary." The motion having been seconded in highly complimentary terms by Mr. H. L. PRICHARD, was carried unanimously.

Mr. MICHAEL briefly acknowledged the honour done him, and added that any efforts at his disposal would be devoted to furthering the interests of the Society.

Votes of thanks were then passed to Sir C. Hastings, the President, and to Mr. Sheppard, the Secretary of the Provincial Medical and Surgical Association, for their attendance at the meeting of that day. These votes were duly acknowledged by the gentlemen to whom they referred.

A vote of thanks to the President having been passed and acknowledged by that gentleman, the proceedings of the business-meeting were brought to a termination about five o'clock.

Correspondence.

DR. OGIER WARD ON DR. MEREI'S DESCRIPTION OF TYPHUS.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—In the number of the *Journal* for August 18, in a lecture by Dr. Merai on the diseases of children, the following passage occurs at page 414:—"Abdominal typhus is rare before the eighth, or at least not characterised in the same degree on the intestines as from the eighth year upwards." Again, at page 416, "Asthenic or typhoid fevers, in the majority of cases, can scarcely be recognised before the third or fourth day; and typhus is, even at that time, and in children above the eighth year, frequently ambiguous." From the former of these quotations the reader might suppose that "abdominal typhus" is the "affection typhoid" of Louis and Chomel, who assert that it is rare in children; but in the second quotation a distinction is drawn between asthenic or typhoid fevers and typhus, so that it would seem that Dr. Merai admits two forms of fever in children, viz., typhoid fever, but without intestinal or abdominal complication under the eighth year, and a distinct typhus fever, which is more difficult to diagnosticate than the former. Having begun the study of the morbid anatomy of fevers in the adult under MM. Chomel, Louis, Bailly, and Andral; and in children under M. Guersant, I can affirm that in no instance did I ever examine a body dead from continued fever in Paris, without finding extensive marks of intestinal disease in the form of ulceration of the Peyerian glands, whether in children or adults. "In 1837, during an epidemic typhoid fever in Birmingham, I attended twenty-two cases of fever, of which eleven were below the age of twelve years. All presented similar symptoms, of which the most urgent were cough and diarrhoea. Three cases were fatal, of the respective ages of 23, 11, and 1½ years, and the intestinal lesions found after death were identical in all, viz., the mucous membrane of the stomach ingested, thickened, and softened; the same appearances in the duodenum of the two elder, with great development of the mucous follicles, (glands of Brunner); the glands of Peyer prominent and covered with sloughing ulcers, particularly at the cœcal valve; the mesenteric glands opposite the ulcerations much enlarged; the glands of the colon enlarged and ulcerated, and the rest of the viscera healthy but congested, except the spleen, which was softened also."*

Here the only distinction between the lesions of the adult, the boy, and the infant, was, that the duodenum of the last was not affected. In all the other cases of death from continued fever in children, I have met with the same *post-mortem* appearances; but I have referred to those above because, from the epidemic attacking various ages, there can be no doubt of the identity of the disease. The affection of the Peyerian glands,

asserted by Louis to be characteristic of typhoid fever in its acute form, and of phthisis in the chronic, cannot, I think, be considered as strictly pathognomonic, as I once met with a fatal case of ulceration of the glands and perforations of the intestines in an infant only eight days old. In this instance, after the meconium had been passed, there was jaundice, tympanitis, and obstipation; and after death there was found peritonitis, from effusion of yellow fæces through a perforation of an agminate gland, just above the cæcum, which was also ulcerated, as well as the other Peyerian glands, for some distance up the ileum. Neither Drs. Graves, Watson, nor Copland, make any distinction in the lesions of adults and children from continued fever, though the latter, like Louis, asserts that typhoid fever is most common between the ages of 15 and 40 years. None of these authors, however, speak decidedly and expressly upon this point, and therefore I have ventured to make the foregoing remarks as the result of my own experience, with the hope that if they meet the eye of Dr. Merei he may be induced to favour your readers, in a future lecture, with the conclusions he has drawn upon the morbid anatomy of infantile fevers, whether continued or remittent, from the extensive field of observation he has enjoyed at the Childrens' Hospital in Pesth.

I do not mean to assert that continued fever in adults is always attended with ulceration of Peyer's glands, for Andral, Dr. Watson, and others, have met with cases in which no lesion of the kind could be discovered, and Dr. Lombard, of Geneva, has attempted to draw a distinction between the typhoid fever, thus characterised, and the Irish typhus, attended with petechiæ and vibices, a distinction, however, not admitted by Dr. Graves; but having invariably found ulceration of the intestines in infantile continued fever, which is always attended with more or less diarrhoea, indicative of the progress of the disorganization, it appears to be a most important proof in regard to treatment, to establish as a rule, that whenever other affections may complicate the course of continued fever in children, inflammation of the glandulæ agminatæ always co-exists, and requires our closest attention to guard against its consequences.

I am, Sir, your obedient Servant,

T. OGIER WARD.

Kensington, August 30, 1852.

MR. VIVIAN'S SPEECH AT THE LATE SWANSEA MEETING.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I observe in the report of the proceedings of the Monmouthshire and South Wales Branch of the Provincial Medical and Surgical Association, as reported in the *Swansea Herald* of the 1st of this month, that the Hon. Member for Truro, Mr. H. H. Vivian, who honoured the Branch with his company at the dinner, expressed himself as a friend of medical science, and asserted his willingness to promote the legitimate

objects of its members in his place in the House of Commons.

I take leave to remark on the circumstance, as I have no doubt kind deeds and kind words will not be forgotten by the members of our Association and the profession generally. I feel assured Mr. Vivian's sentiments will be reciprocated by the medical constituencies of the influential borough the Hon. Gentleman represents, and that his interests will be duly cared for by them, and a friendly hand held out to aid him whenever opportunity offers.

I trust the medical profession has many such friends as the Hon. Gentleman in question; and I sincerely hope, in election matters, they will be duly appreciated and favourably recollected—"verbum sat." It is equally our duty and our interest to know our friends and to serve them faithfully, and remember them gratefully.

I remain, Sir, your obedient Servant,

A MEMBER OF THE PROVINCIAL MEDICAL
AND SURGICAL ASSOCIATION.

September 8, 1852.

[The speech in question was made at the dinner, of which we have not given a report.—ED. J.]

Foreign Department.

MATERIA MEDICA.

On Iodized Cigars.—It has been suggested by Kletzinsky that the iodized cigars introduced by Charroule and Bertow might be advantageously used more generally in medicine. He finds—

1. That a sufficient quantity of iodine may be found in a cigar which, after being iodized, has been lying exposed for four days in a warm room. (We may observe that the process of iodizing consists in lightly washing a cigar with an alcoholic solution of iodine, or in exposing it for a few minutes, in a closed box or vessel, to the simultaneous action of iodine vapour and steam.)

2. The greater part of the iodine which has been taken up is found in the ash as iodide of potassium, calcium, and magnesium.

3. The smoke, after being passed through cotton wool to retain any particles of ash, and then conducted through a neutral solution of starch, did not give rise to the slightest blue coloration, even after the neutralization of the carbonate of ammonia contained in the smoke, with acetic acid. On the addition, however, of chlorine water or nitric acid, a blue tint was evolved, showing that there was a little iodide of ammonium, although no free iodine, in the smoke.

4. After a few puffs, the saliva and buccal mucus gave distinct, although slight, traces of combined iodine.

5. After smoking an iodized cigar, iodine could generally be detected in half an hour, and often earlier, in the urine.—*Kletzinsky in Wien. Med. Wochenschr.*, No. 39, 1851.

Kousso as a Remedy for Tape-Worm.—The three following cases of the successful application of this remedy, are recorded by Dr. Oliari, Director of the Hospital at Cremona:—

1. A woman, aged 36, had for four months frequently passed pieces of tape-worm (*vermis solitarius*) with the evacuations. Without any previous treatment she one morning took five drachms of kousso, with sufficient honey to make an electuary, in two doses, the second two hours after the first. Two hours after the last dose she took an ounce of castor oil, and another ounce two hours later. In the course of the day she discharged a large number of pieces of tape-worm, from one to two inches in length; and since that time [the period is not stated—Ed.] appears perfectly free from the disease.

2. A girl, aged 16, took the same quantity, similarly divided, in the form of a warm aqueous decoction, and followed it with castor-oil in precisely the same manner. Besides many fragments, she discharged a portion of worm twenty-two ells in length, with a very pointed extremity and short joints, such as occur near the head. The head itself could not be perceived. Since this time (a period of two months) she has been quite free from the disease.

3. A man, aged 40, had suffered from tape-worm for several years, and had tried many remedies, which, strange to say, failed to bring away any portion of the worm, although pieces were often observed in the ordinary evacuations. After taking five drachms of kousso (in an electuary,) he passed several pieces of worm (*tania sol*), six or eight ells in length. He has had no return of the disease.

The two following cases of a similar nature are recorded in the same journal, by Dr. Vincenzo Masserotti:—

1. A man, aged 40, had from his earliest childhood, at different intervals, passed pieces of botriocephalus. He had tried the ordinary remedies in vain; his symptoms were increasing in intensity, and he dreaded the same fate as a brother, who had died from insidious gastro-enteritis, induced by the same parasite. Although, after taking the kousso, he interfered with the treatment by obstinately drinking seidlitz water, which induced severe vomiting, yet several pieces of worm were discharged, one of which was twelve ells in length, and had the head attached to it.

2. A woman, aged 33, had for the last eight years often discharged pieces of tape-worm, and had suffered from painful tremors of the limbs, pain in the abdomen, palpitation of the heart, hypochondriasis, and emaciation. After five drachms of kousso, she passed several portions of worm, to one of which the head was attached. None of these portions exhibited any signs of vitality, although pieces she had previously passed showed indications of life when kept in water for two hours. Hence the poisonous power of the drug in relation to the worm is well shown in this case.—*Gazz. Med. Ital. fed. Lombard.*, No. 46, 1851.

On the Potio Choparti as a Remedy for Hæmoptysis.
—The following is the formula for this medicine.

now used in the *Charité* Hospital at Berlin:—*R.* Balsami. Copaivæ; Syrupi Tolutani; Aquæ Menthæ Pip.; Spirit. Vini. Rectificatiss. utr., oz. j.; Spirit. Nitric-Æther., dr. iss. Miscæ. A teaspoonful for a dose. The mixture requires shaking before use, as the balsam of copaiva separates, and floats on the surface. The taste is not disagreeable; it is slightly irritating, but not sufficiently so as to induce cough. Dr. Wolff has for two years used this combination in a large number of cases of hæmoptysis depending on pulmonary tuberculosis; and the general results have been so favourable that the medicine is now permanently introduced into the hospital pharmacopœia. At first he only tried it when other means had failed, but now it is the remedy on which he chiefly relies; and he uses it in most of these cases. If it causes vomiting, its application must be suspended, or altogether discontinued.—*Wolff in Ann. d. Charité zu Berlin*, Vol. 2, No. 2, 1852.

Tannin in Hooping Cough.—Dr. v. Brewning employs tannin in the following combination, in cases of hooping cough:—*R.* Tannini, gr. 1-6th; Acid. Benzoic., Extract. Belladonnæ, utr., gr. 1-12th; Pulv. Rhei, gr. iij.; Pulv. Gumm. Acaciæ, gr. xij. *M.* Fiat pulv. The powder may be given three or four times a-day. For a very young child half the dose twice daily will be sufficient. In a few days the severity of the symptoms usually diminishes, and the character of the attack changes. If the *primæ viæ* require clearing, an emetic dose of antimonial wine should be first administered. If the disease does not yield in a few days, and the periodicity of the attack is well-marked, one or two grains of hydrochlorate of quinine [The disulphate would, doubtless, be equally efficacious.—Ed.] may be substituted for the rhubarb. He recommends, as a domestic remedy, the simultaneous use of a tea of the flowers of the common primrose, with equal parts of inspissated crab-juice and sugar-candy.—*v. Brewning in Deutsche Klin.* No. 6, 1852.

PATHOLOGY AND PRACTICE OF PHYSIC.

The Post-mortem Appearances in a Case of Hydrophobia.—Dr. Middeldorpf relates the case of a man—a confirmed drunkard, who had been several times treated for delirium tremens—who was bitten in the last phalanx of the first and second finger of the right hand by a mad dog, on the 26th of July, 1851. As the dog was unquestionably rabid, the man was, on the 4th of August, admitted into the hospital, that his case might be watched. On the 26th of that month he was seized with the symptoms of hydrophobia, which carried him off within twenty-four hours. There is nothing in the treatment or in the symptoms to call for special remark, but as carefully-conducted *post-mortems* in this disease are still a *desideratum*, we give the results of the *sectio*.

There was much thin fluid blood in the superior longitudinal sinus. The pia mater and arachnoid were opaque, and milky; under the pia mater, both on the surface of the brain and on the lateral ventricles, there was a thin layer of serum. Both the grey and the white

substance were more full of blood that is natural, especially the former. The medulla oblongata was of the normal firmness. The bones forming the vertebral canal abounded in blood. The grey matter of the spinal cord was softened to the consistence of a pulp, the lower half of the uppermost enlargement of the cord being the most disintegrated, and being reduced to a homogeneous, greyish, red mass. There was nothing abnormal about the pneumogastric nerve, or the nerves or vessels of the axilla. The papillæ vallatæ of the tongue were very prominent. The larynx and trachea were slightly reddened, and the bronchial mucous membrane was of a dark-red colour. The lungs contained much light red blood, but very little air. There was no excess of serum in the pericardium. The heart was relaxed and flabby, and its tissue was of a pale-brown colour; it contained a good deal of non-coagulated blood. There was fatty liver. The spleen was enlarged, very friable, and of a pale chocolate colour. The kidneys were large and pale; the pancreas very vascular. Nothing abnormal was observed in the stomach, intestinal canal, pharynx, or œsophagus. [We need hardly mention, that many of the latter appearances—as those of the heart, liver, kidneys, &c.—can have no connection with the special disease, but depended on the previous habits of the patient.—Ed.]—*Middeldorpf in Günsburg's Zeitsch.*, Vol. 2, No. 6. 1851.

Symptoms of Bright's Disease, which, taken alone, might Simulate other Diseases.—Professor Christensen, a Danish physician, who has already published several important memoirs on Bright's Disease, has just published a paper bearing the above title (in the Hospital's *Meddeleser*, vol. 3, part 5).

That the primary pathological condition in Bright's disease lies in the blood is obvious from its morbid products, namely, the exudation of an albuminous fluid into the cellular tissue and the serous and mucous membranes; it is likewise shown in rarer cases by the retention of urea in the blood. This morbid secretion from the blood into the different parts of the body does not by any means occur simultaneously; it sometimes only presents itself in one part, but is more commonly followed by effusions into other parts or organs; moreover, if the effusion into one organ be suspended, it usually commences in some other part. Hence it is obvious that the symptoms may be very various, and that many phenomena which we might expect in the ordinary form of this disease, may be absent, so that, unless a proper examination of the urine be instituted, grave errors of diagnosis may be made. Christensen observes, that the symptoms which may simulate other diseases, are especially those of the brain, the air-passages, the stomach, and the intestine.

Cerebral symptoms are a consequence of retention of urea in the blood when the urinary secretion is suppressed or diminished, although it may sometimes occur when there is scarcely any apparent diminution of the quantity of urine. In these cases chemistry reveals the presence of urea in the blood to very considerable quantity, and occasionally a lesser quantity in the other

fluids of the body. The morbid changes which the kidneys undergo in Bright's disease, may give rise to a suppression of urine, and if this suppression be gradual, the cerebral symptoms also come on gradually, and a peculiar apathetic soporose condition is observed. The blanched, and often somewhat puffy, cachectic countenance, has a peculiar expression hard to describe; the pupils are normal, or rather dilated, but are torpid in contracting. When the disease is slowly developed, there is occasionally a little wandering and mental disturbance (the quieter form of delirium); when it advances rapidly, there is delirium of a much more marked, although never of a furious, character. Hallucinations do not seem to occur, but there is often loss of consciousness. An involuntary and shrill scream is often uttered; and we sometimes observe a peculiar grasping action of the hands, or a fighting-like movement of the arms. There are also involuntary movements of other parts of the body, especially of the head; and convulsions of the muscles of the face are by no means rare. At length a comatose state supervenes; there is prolonged, tracheal, laborious, and sometimes stertorous respiration; and deglutition becomes very difficult, or is altogether impeded. The pulse is very uncertain, often slow, (not above 60,) never very rapid, usually about 100 in the minute. The excretions are passed involuntarily.

Christensen gives two cases in illustration of this class of symptoms:—

Case 1.—A woman, aged 27, was seized with peritonitis, (a slight attack,) four months after delivery. During her convalescence she was suddenly attacked with somnolence, accompanied with diminution of secretion from the kidneys, and albumen in the urine; these symptoms continued for three days, when she died. On examination the kidneys were found to be in the third stage of Bright's disease.

In reference to this case he observes, that a perfect suppression of the urine is not necessary for the development of cerebral symptoms.

Case 2.—A woman, aged 28, who had not menstruated for six months, was brought into the hospital in convulsions. On subsequently examining her, the only circumstance pointing to Bright's disease, was pain in the lumbar region, extending down the thigh. Two days after admission convulsions again supervened, which carried her off in eighteen hours. On dissection the characteristic degeneration of the kidneys was revealed.

Of the symptoms connected with the air-passages, the most prominent are a peculiar laborious respiration, something like that which occurs in croup, but more closely resembling that which accompanies syphilitic ulceration of the larynx. There is more or less dyspnoea, but cough is not invariably present. On auscultation we detect a widely-distributed sonorous and blowing rhonchus in the lungs, which can often be heard at some distance. The anatomical indications of this condition are merely a diffused redness and puffiness of the mucous

membrane of the air-passages. This affection of the trachea and bronchi is often combined with dropsy and other symptoms of Bright's disease; and as one symptom often acts vicariously to another, so an attack of this kind of bronchitis often takes the place of vomiting or diarrhoea, or becomes more intense when the oedema diminishes. The author gives two illustrative cases:—

Case 1.—A woman, aged 28, who shortly before had been cured of oedema arising from Bright's disease, took fever, which was accompanied by disturbed respiration, dry skin, and hoarseness; there was difficulty of speech, and there were attacks of orthopnoea, with considerable cerebral congestion and epistaxis. There was no pain in the larynx or trachea, or in the chest; but there was a slight sensation of weight in the pit of the stomach. The patient could lie on either side. Pulse from 80 to 100, and tense; tongue moist, and almost clean; bowels open. Widely distributed sonorous rattles were heard in both lungs, and there was very prolonged expiration. One venesection was ordered, leeches were applied, and a solution of tartarised antimony prescribed. On the following night great dyspnoea came on, and she was in a state of impending suffocation, with a livid swollen face, loss of consciousness, and a short rough cough. After vomiting several times, the respiration was somewhat relieved, but the act of expiration was accompanied with much difficulty; the face exhibited an expression of great anxiety, the pulse was rapid and somewhat tense, and there was no delirium. Leeches were again applied to the larynx, and the tartarised antimony continued. The symptoms, however, continued to increase, and she died on the eleventh day after her admission. A few days before death tracheotomy was performed, which gave temporary relief.

On a *post-mortem* examination, it was found that the epiglottis, and the mucous membrane above the glottis, were pale and not swollen; below the glottis the mucous membrane was dotted with fine red points, to the ultimate extremities of the bronchial tubes. It was not swollen, nor was there any false membrane; but it was covered with frothy mucus. The right lung was sound; the left was somewhat infiltrated with a serous bloody fluid. The heart was healthy. Both kidneys were of the normal size, but were very hard and irregular on their surface. The cortical substance was very hard, and of a whitish-grey colour, smooth, and without granulations; the pyramidal bodies were in many places much thronged together. The author believes that such cases as this one should be treated as tracheitis, even if we detect the true nature of the disease, since we can never be quite certain that these attacks may not depend on a genuine inflammatory process.

Case 2.—In this case it appeared as if a syphilitic ulceration of the larynx were present. The most prominent symptoms were hoarseness, shortness of breath, redness of the interior of the nostrils, with foetid discharges from them; a sensation of dryness in the throat; and, finally, a febrile condition, with difficulty

in deglutition and respiration. The urine was examined on the day preceding the patient's death, but contained no albumen. In consequence of the increased difficulty of respiration, and on the supposition that some mechanical impediment was the cause of this and of the dysphagia, tracheotomy was performed, without, however, any satisfactory result, for the patient died in a comatose state within eighteen hours. After death nothing abnormal was found in or near the larynx; there was slight oedema in the lower part of the lungs, a nutmeg liver, and a very large and hard spleen. The kidneys were passing into the last stage of Bright's disease. The brain and its membranes contained an excess of blood, and there was a little serous effusion. The urine found in the bladder contained much albumen. The author suspects that the urine already referred to as containing no albumen must have been passed by another patient; had he then found albumen he would not have ordered tracheotomy.

Gastric and Intestinal Symptoms.—Although vomiting and diarrhoea are amongst the most frequent of the symptoms which characterise Bright's disease, either or both are very rarely the only symptoms. Christensen has only seen six instances of this nature in several hundred cases. The vomiting rapidly debilitates patients; and if it is not supplanted by some other symptoms, as diarrhoea, a severe attack of bronchitis, well-marked oedema, or increased diuresis, it may prove fatal in a week. In one case the vomiting continued at intervals for a year and a half, in another case for about half a year. At first the vomited matters consist chiefly of mucus, but in a later stage they contain bile. The vomiting, unless when very continuous and severe, is unaccompanied by any very marked pain in the gastric region. Hiccough and eructations sometimes occur. Diarrhoea is one of the mildest symptoms of Bright's disease; and the author believes the extensive mucous surface of the intestinal canal separates and removes a large quantity of morbid secretion; and thus relieves other organs. As the diarrhoea depends on a simple exudation of albuminous fluid, without any inflammatory process, it gives rise to no pain; sometimes, however, a diphtheritic inflammation of the lower part of the ileum or of the colon is simultaneously present. Unless the latter complication is present the intestinal discharges are not mixed with blood or mucus, but are merely their liquid excrement. We have only space to notice the *first* of the *six* cases recorded by Christensen. In this case vomiting was the predominating symptom. The patient was supposed to be suffering from a slight attack of typhus, and his urine was not examined. On dissection, it was found that the cortical substance of the kidneys was hypertrophied, and that the pyramidal bodies were much atrophied; the tissue was hard, firm, and pale. The urine found in the bladder contained much albumen.

Reviews.

Disease in Childhood, its common Causes, and Directions for its Practical Management. By ROBERT ELLIS, F.L.S. London: G. Cox, King William Street. 1852. 12mo, pp. 288.

It is much to be desired that in all cases where authors are writing for the express use of the public, they should broadly state the fact in their title pages. This precaution would prevent much disappointment, and would certainly not tend much to diminish the sale of the work, since its omission as often leads the individual who really wants the information afforded, to avoid the purchase, as it tempts the professional reader to procure a volume which has no information useful to him. These observations have been called forth by the work whose title is copied above, and from which, as well as from the preface, we certainly were led to expect a treatise adapted to the wants of the profession, whereas it is quite clear, indeed in the body of the book it may fairly be inferred, that it is solely intended for the use of families. For this purpose we can certainly advise our readers to recommend its perusal by their patients, though perhaps it may be open to the objection of intrusting too much of the medical treatment to the hands of the mother or nurse. There is, however, much sound practical information, and with the above exception, we certainly have no fault to find with the author.

Whilst on the subject of children's diseases, we may draw attention to the favourable mention made in the last number of the "British and Foreign Medical Review," of one of the former publications of our esteemed contributor, Dr. Merei, who is now permanently attached to the Chatham Street School of Medicine, Manchester. In the article in question, Dr. Merei is introduced as follows:—"We pause for a moment to draw the attention of those interested in the pathology of the diseases of children, to a name to which much praise is due, as those who are acquainted with the work of Dr. Hügel (reviewed in our fifth volume, page 362) will be sufficiently aware. We allude to Dr. Schoepf Merei, whose work is mentioned at the head of this article, and we may here observe, that to this Hungarian physician is due the existence of a Children's Hospital at Pesth, &c., &c." After mentioning the successful efforts of Dr. Merei in this branch

of medical science, the review concludes with the wish that the above treatise of Dr. Merei (written in a foreign language) may be but a prelude to others, "clothed in the garment of our mother tongue. Previous to the political disturbances in 1848, which drove Dr. Merei from his country and home, he held an exalted position, both as a private physician, and as Professor of the History of Medicine in the University of Pesth, as well as chief physician of one of the first establishments for diseases of children which anywhere exist. It appears, indeed, from the work of Dr. Hügel, already quoted, who is himself chief physician to one of the Vienna Hospitals, and is consequently competent to judge, that the Children's Hospital of Pesth has been highly appreciated for its excellent organisation and completeness, and that at that time, with the exception of Paris and Vienna, there was scarcely one which could compete with it in opportunities afforded for the diffusion of practical knowledge in the diseases of childhood.

From the instruction which we have ourselves derived from the lectures already published in this *Journal*, and from the terms in which many of our correspondents have expressed themselves to us, we are sure that we shall gratify our readers in announcing that Dr. Merei intends shortly to publish a revised edition, considerably extended and amended, so as to form a complete and systematic treatise on the diseases of children. We do not know precisely the time when he contemplates their publication, but we would suggest some slight delay, since every day will add to their permanent value, by familiarising Dr. Merei with the peculiarities of our customs, our climate, and our constitutions; and when the principles which have been laid down so successfully in Pesth, have been practically modified in this country by a slightly longer residence among us, we venture to predict that the product of his brain will be received as the standard work in this department of our art, throughout the length and breadth of our land.

Traité des Fistules Vesico-Uterines, Vesico-Utero-Vaginales, Entero-Vaginales et Recto-Vaginales, par A. J. JOBERT de Lamballe, Docteur en Médecine, &c., &c. Un Vol. in 8vo. Paris, 1852. J. B. Baillière.

THE object of the above treatise is to show, that in all operations for the cure of those distressing

fistulas connected with the bladder, uterus, and rectum, it is necessary not only to pare the edges of the fistula and to bring them in apposition by suture, *but also to supply from the adjacent parts the loss of substance which has taken place.* M. Jobert maintains that all vesico-vaginal and vesico-uterine fistulas, except where the vagina is reduced to the size of a crow-quill, and even those fistulas in which the bladder, womb, and rectum, are all opening into one cloaca, are capable of alleviation by autoplasmic operation, and that by means of the univalve speculum, without having recourse to any division of the perinæum, this operation may always be concluded.

The results of M. Jobert's practice, as detailed by him, are so completely at variance with the acknowledged want of success in this country, in similar operations, that we can scarcely give full credence to his assertions. But nevertheless, it is not because these accidents are the *opprobria* of our art in this country, that we should resolutely shut our eyes to what is put forth in another, and therefore we have thought it right to draw the attention of those who may be called upon to treat any of the various forms of fistula, to the work of M. Jobert.

In the treatment of vesico-vaginal fistula, M. Jobert leans to the simple occlusion of the ostium, in which case the secretions from the lining membrane of the uterus are all poured into the bladder through the original fistula, and the incontinence of urine is got rid of, which is the most disgusting symptom attendant upon these unfortunate cases; but in addition, he gives a method of operating, which, however, does not appear to partake of the nature of autoplasty, but simply to consist in a tedious dissection and final paring of the lips of the fistula, which is then to be brought together by suture.

In proceeding to operate upon those lamentable cases in which the vesico-vaginal septum is destroyed as well as the anterior wall of the uterus, M. Jobert sometimes makes use of the neck of the uterus itself to supply the deficiency, and he finds that union by the first intention is procured as easily as in any other structure. In other cases the labia are the parts which are compelled to take a new position in supplying the defective parts; and sometimes even the cellular couch surrounding the orifice of the urethra, with a part of that organ included.

In the details of the operation M. Jobert is most minute; and as far as description can supply the place of ocular demonstration, his book will be sufficient for all who may think it desirable to follow his steps. We may remind our readers, that the operations described have all, or nearly all, been performed in public, and that the treatise is published in Paris, where the correctness of the statements may easily be ascertained.

Provincial Medical & Surgical Journal.

WEDNESDAY, SEPTEMBER 15, 1852.

EVERY trial for malpractice is one of the saddest of public scandals, for of necessity it implies gross ignorance and neglect on the part of the medical practitioner, or 'the extreme of ingratitude' in his patient, or in the relatives of the patient. If the medical man be not culpable he must be a martyr. However complicated were the forms of judicature when Greece and Rome were in their splendour, we are not aware that they had to deal with this form of suit. It is an offspring of our civilization. In Italy and in the southern states of Europe it is still unknown; it is of extremely rare occurrence in Germany. In France this scandal sometimes occurs. It is more frequent in England, and of common occurrence in America. If America occupies in this respect so unenviable a position amongst nations, it depends upon the low standing of the medical profession in that country, where universities rise as easily as Sunday schools amongst us, (each university turning out M.D's. as fast as our gardeners do mushrooms;) it depends also upon the low standing of the morality accepted in the United States. It is not likely that life and the blessings of health should be adequately appreciated by a people who have so little respect for human nature, that they doom to slavery those whose skins are a little darker than their own. It is not likely that the claims of the most learned of the grave professions for services less tangible than cotton bales, should be always admitted by a nation who consider piracy fair play, and who diligently rob of their well-deserved reward, those whose industry or genius have added to that stock of literary lore, by which the human mind is either instructed or amused. Why should not the doctor's claim be

repudiated, since the States repudiate their debts? The logic of crime is inexorable, and after pillaging foreign shareholders, it is but fair that they should plunder each other.

These remarks have been suggested by a case of trial for malpractice, which has lately excited great interest in the west of England, and we intend to draw our readers' attention to it because it will lead to some remarks of practical import to all, for we are all liable every day of our professional career to be implicated in such a trial, either as defendants or witnesses.

The case we allude to was tried at Exeter, at the last summer Assizes, and although the trial lasted seventeen hours the case is very simple. The wife of a dealer in surgery fittings went, under a false name, to seek gratuitous advice of Dr. ROE, of Plymouth. After two months' attendance Dr. ROE suspected some uterine disease, and when he detected ulceration of the neck of the womb by an examination, he told the patient that the case would be long and difficult, that he could no longer attend her gratuitously, but if her husband approved of his attending her in the usual way at her own house, he would do so. This was agreed to, the patient gave her real name, and remained nine months under Dr. ROE's care, proving her satisfaction by repeated presents. But Christmas came, and as Dr. ROE practises as a surgeon, he sent in his bill of twenty-seven guineas. Then it occurred to the woman to go to another medical man, Dr. PRANCE, of Plymouth, who, after making a digital examination of the womb, said that there was nothing the matter with her, and advised her to consult Mr. WHIPPEL, of the same town, whose patient she had formerly been. Unfortunately there had been previously to this, some professional collision between Dr. ROE and Dr. PRANCE, and he, in addition, also advised the woman to go to a lawyer. She acted upon both parts of his advice, and, after a very stormy meeting with Dr. ROE—when it seems both parties alike forgot themselves—the woman sued Dr. ROE in the County Court, but Dr. ROE removed the cause by *certiorari* to the Exeter Assizes, where it was tried before a special jury.

Now, from a careful consideration of the case, and from conversing with some of those who attended the trial, it is evident to us that the woman had been some time suffering from tertiary symptoms of syphilis when she first consulted Dr. ROE. Such was his diagnosis: such

had previously been that of Mr. WHIPPEL, and her counsel did not attempt to deny the point. It is also evident to us that she was affected with uterine disease. Her first nurse, during Dr. ROE's treatment, testified to the usual uterine pains, and to a yellow discharge, and if the nurse who subsequently attended the patient swore that this was not the case during her attendance, we think it right to side with the jury, and lay on her shoulders the onus of perjury, since, as Baron PLATT remarked, it must be borne by the witnesses of one of the parties. We are further justified in so doing by one of the patient's own medical witnesses, Mr. WHIPPEL, confirming Dr. ROE's statement of the case; for a day or two after Dr. PRANCE had pronounced the woman free from all uterine lesion, Mr. WHIPPEL examined her with the speculum and found "an abrasion of about the size of a split pea," on one of the lips of the neck of the womb. Dr. ROE could not, therefore, be accused of not having detected the nature of the disease, and with regard to his treatment of the patient, whether as afflicted with syphilis or with uterine disease, it was that of most medical men, and that recommended in most works on such complaints; it was difficult, therefore, to tax him with ignorance, and as for neglect of his patient, his great attention to the case prevented this plea being even urged. Such will be the view most medical men will take of the case, and the light in which the English jury viewed it, or they would not have acquitted Dr. ROE. But Sergeant KINGLAKE was instructed to state, contrary to the evidence of the nurse, that the plaintiff had no uterine disease until Dr. ROE began his treatment, and that his treatment alone reduced her to debility and helplessness, a statement strangely at variance with the fact that she repeatedly sent for him at all hours of the day, and of her own accord.

Another accusation repeatedly brought forward by Sergeant KINGLAKE against Dr. ROE, was his scarification of the womb; and without defining what was meant by scarification in medical practice, he, in the same breath, accused Dr. ROE of cutting, maiming, and lacerating. "Lacerating the womb" was an expression calculated to tell upon the jury, and the counsel repeated it over and over again, and even brought a witness to prove, that after one of those terrible lacerations of the womb the patient actually lost *two tablespoonfuls*

of blood. None of Dr. ROE's legal advisers drew the Judge's attention to the fact of this monstrous accusation, being emphatically contradicted by the plaintiff's own medical witnesses, for Dr. PRANCE asserted that the neck of the womb was sound, and Mr. WHIPPEL that it was so, with the exception of an abrasion; now, if the neck of the womb had been frequently lacerated, it would have certainly presented irregular cicatrices. But the grand element of the plaintiff's case in which the learned Sergeant displayed great ingenuity, was, that quackery had assumed a new form of late—that Dr. ROE was a *speculum* doctor, and that he was not warranted in using the speculum in the case.

Dr. BUDD, of Plymouth, appeared on the plaintiff's behalf to say that when a young man he used to employ the speculum, but that since he had grown wiser he seldom did; and that he would not meet several London physicians who found it necessary to use this instrument frequently. His sweeping condemnation of a mode of examination often indispensable, was counteracted in its effect upon judge or jury, by the evidence of Dr. TILLY, of London, Mr. NORMAN, of Bath, and six other medical practitioners of good standing in Plymouth and in Exeter, who all approved of the plan of treatment adopted by Dr. ROE.

Singularly enough, while Sergeant KINGLAKE was declaiming against the speculum, his client's case gave a striking proof of its utility, for while, by making a digital examination only, Dr. PRANCE pronounced the plaintiff's womb to be perfectly healthy, Mr. WHIPPEL, on making a speculum examination, discovered an abrasion which Dr. PRANCE would perhaps have seen, had he adopted the same means, in which case he certainly would not have directed the unfortunate woman to the lawyer.

We cannot conclude without remarking, that in proportion as the standard and moral tone of our profession is raised, in the same proportion will trials like the one to which it is our painful duty to draw attention become scarce. There must be many circumstances to render such a trial possible. In this instance the patient's ingratitude was fanned by professional jealousy, the corroding canker which causes so much individual misery, and deprives the profession, considered as a body, of that power which always springs from unity of mind and purpose.

The manner in which Sergeant KINGLAKE

considered *scarification* and *laceration* as synonymous, must impress upon all medical practitioners the urgency of giving the solicitor of the case in which they may be connected in any way, the clearest definition of the medical terms that may be used, so that—as in the present case, an unfair use may not be made of a term having a popular as well as a medical meaning.

It is an acknowledged principle of the law of the land, that every wrong has its remedy, and as an example, that even the dicta of a judge, if founded in error, can be remedied in their effects upon a jury by a new trial, until which takes place, everything remains *in statu quo*. Upon this principle we have argued the various points in our discussion of the "Journal question." We thought and still think that an injustice has been committed in the course of the proceedings at Oxford, relative to the publication of the *Journal*, which proceedings were, as we believe, based upon an illegal notice, supported by incorrect statements—which could not there be discussed, and carried in an irregular manner. But we find by the resolution of the Bath Council, which is composed of gentlemen every way fit to investigate the matter with impartiality, that our conclusions are not supported by them, though they admit the correctness of the facts upon which they are founded; we therefore agree with the Worcester Council, in thinking it better, under all the circumstances of the case, to throw the entire responsibility upon the Committee, of carrying out this fundamental change in our proceedings, and we publish the following resolutions, without further comment, and shall, as far as we are concerned, henceforth dismiss the matter as *un fait accompli*.

At a meeting of the Central Council, held on Saturday, the 11th inst., the following resolutions were unanimously passed:—

Resolved,—

"That the Central Council, having ascertained from many influential members of the Association, that the general feeling is in favour of the validity of the resolution passed at Oxford, with regard to the *Journal*, are of opinion that it is not desirable further to insist upon the informality of Dr. Cowan's proposition."

It was also Resolved,—

"That the Secretary be requested to send the foregoing resolution to the Editor of the *Journal*, for publication, and also to Dr. Cowan."

Since writing the above we learn that Dr. CORMACK, of Putney, has been appointed the future Editor of the *Journal*.

It is with deep regret that we publish the following particulars of an action in the Bath County Court, for malicious arrest, brought by a person of the name of BOURN, against Mr. W. A. Cox, surgeon, of Bath, and a member of the Provincial Medical and Surgical Association. It appears from the evidence, as reported in the *Bath Chronicle*, that Mr. Cox had attended BOURN for five weeks, in June and July last, when, hearing that he was about to leave the country, Mr. Cox, without making any application to him, obtained a Judge's order, under the Absconding Debtor's Act, for the amount of his bill, viz., £21. 5s. He then followed BOURN to Bristol, in company with his attorney, and compromised the matter by receiving £15 in full of all demands for bill and costs, BOURN returning to Bath in Mr. Cox's gig. Soon after this, the above action being commenced, Mr. Cox sent in a bill of particulars, from which we extract the following items, the remainder being of a precisely similar character:—

1852.

MR. FRANCIS BOURN,

To W. A. Cox, Surgeon.

In a Case of Syphilitic Ulceration of the Foreskin and Gonorrhœa, with Phimosis, Bubo, and Stricture of the Urethra.

June 16th.—Long consultation in your case which had been improperly treated and neglected, dressing ulcers, fomenting and poulticing bubo, and passing bougie	£0 10 6
Two bottles of mixture	0 5 6
Three mercurial powders	0 1 0
Attendance in the evening, dressing ulcers, fomenting and poulticing bubo, and passing medicated bougie	0 10 6
18th.—Consultation and attendance, dressing ulcers, fomenting and poulticing bubo, and passing bougie	0 10 6
Two bottles of mixture	0 5 0
Attendance in the evening, dressing ulcers, fomenting and poulticing bubo, and passing bougie	0 10 6

* * * * *

July 20th.—Consultation and attendance, when I found the disease had been all but subdued, the ulcerations healed, the induration of the foreskin gone, the bubo and stricture cured, and the only remaining symptom was a slight gleet, for which I passed a medicated bougie, the system being in too delicate a state to admit of the exhibition of internal remedies, likely to stop the discharge...	0 10 6
Attendance in the evening, passing medicated bougie	0 10 6
24th.—One bottle of mixture	0 3 6

Total £21 5 0

The above is an explanatory bill of the charges in my ledger; I make it out thus that the parties may have some idea of the nature of the case, and of the services rendered. Each attendance occupied a very considerable time.

I regret to be obliged, in self-defence, to set out my charges so minutely.

W. A. Cox.

It was asserted by BOURN's attorney that this bill was concocted for the purpose of raising the sum above £20, which is the lowest amount upon which a Judge's order can be issued, and we leave our readers to form their own opinion upon the matter. Evidence was given on both sides, as is unfortunately too often the case in all professions, but here we think all must agree that the bill is not such as ought to be sent in under ordinary circumstances; indeed Mr. Cox admits that he should not have charged in this manner, if his patient had come to him for the purpose of discharging his debt. On examination of the books of Mr. Cox by the Judge, his Honour was of opinion *that the various visits charged in the bill had been interlined at a period subsequent to the time at which the medicines, &c., were posted*, and we are sorry to be obliged to announce that the jury expressed their opinion of the case by giving a verdict against Mr. Cox, with £15 damages.

The above case is in every way unfortunate; for, granting that the visits were an addition for the purpose of increasing the amount to meet the legal requirements of the case, still we can scarcely suppose that forty-two bottles of mixture, and the same number of mercurial powders, could be required in the space of five weeks. The public have, therefore, a fair charge against a member of the profession of overdrugging his patient, on evidence of his own affording, and in these days of homœopathy we can ill afford to give such a handle. But, unfortunately, it does not stop here, for, unless Mr. Cox takes some further steps to upset the judgment, or to do away with its effects by explanation, he stands convicted of "gross fraud," which, according to the Judge's summing up, was the point put to the Jury, who were directed "not to give a verdict against the defendant, unless they were satisfied that there was no reasonable doubt in the case as to his having committed that which had been described as a gross fraud—one of the most disgraceful frauds which any man, in any station of society, could be guilty of." * * * "The question for them was, whether Mr. Cox had fraudulently aggravated the bill for the

purpose of enforcing the arrest." The imputation, therefore, is so serious that we call upon Mr. Cox to meet the case, if possible, and we shall be most happy to publish such an explanation as he may be able to offer. For the sake of the profession to which he belongs, we cannot but hope, even against conviction, that there is some apology to be made, which could not appear in a court of justice.

Medical Intelligence.

(From our own Correspondent.)

LONDON, SEPT. 13, 1852.

[OWING to our absence in London in attendance on the Committee on the Medical Bill, a considerable and important portion of the memoir of the late Dr. Herbert Mayo, was omitted in our last communication. As the omitted part contained the explanation of the reasons which led him to subject himself to the hydropathic treatment, and subsequently to practise as a hydropath—a proceeding on his part which gave rise to great obloquy, in justice to the dead, it is published in this letter. It refers, also, to his literary labours, of which it gives a succinct account.—ED. J.]

We are not aware when Mr. Mayo's health was first shaken by the attack of disease—rheumatic gout, which ultimately disabled him for the performance of his duties, and compelled him to retire to Germany; neither do we know the precise causes, whether hereditary or acquired, to which it is to be attributed, but certain it is that, as is usual in such cases, every fresh attack left more and more serious consequences behind it, in the shape of enfeebled health, crippled joints, and less capability to bear up against the invasion of disease, every attack being more and more severe and more and more prolonged than its predecessor. After the lapse of some years, during which his sufferings were very great, all the known remedies failing to afford him any relief, the larger joints became the seat of false ankylosis, and he was ultimately so completely crippled, as to be unable even to move without assistance. Under these circumstances, he resigned his professional appointments, his connections with the Middlesex Hospital ceasing in 1842, and soon afterwards he went to Germany to try what the then apparently new system of hydropathy would do for him, he being advised to take that step by several medical friends of high reputation and deserved eminence in the profession, who candidly confessed that the resources of art had been unavailingly exhausted in his behalf, and therefore, as the old principle, that *anceps remedium melius est quam nullum*, that the mode of treatment advised by Preissnitz, might now have a fair trial. His friends did not give him much hope, even as regards obtaining relief; as to a cure, such a thought never entered their minds. Dr. Mayo's having recourse to the hydropathic treatment, has been spoken of by a cotemporary as an instance of insanity; if it were such—and we by no means look upon it in that light, he was not alone in the matter, as his professional friends in this respect were as deep in the mud as he was in the mire. The fact is, that after years of severe suffering, such as only martyrs to rheumatic gout can be judges of, and after having been assured by those who were best capable of forming an accurate opinion on the matter, that medicine could do no more for him, he resolved to give the Silesian peasant's mode of treating disease a fair trial, just as "drowning men catch at a straw," knowing that if it did him no good, at all events it could not make his state much worse. Under such circumstances, how few are they

who would not do the same? In this respect we have but small claim to blame him: he was a martyr to disease, and past all hope of cure or relief by legitimate medicine, and was unwilling to die *secundum artem*, without at all events making a struggle for it. He did not in this secede from the ranks of legitimate medicine, until he had been thoroughly crippled by the attacks of incurable disease, causing ankylosis of the larger joints.

Nor was he altogether deceived: when he left England he proceeded to Muhlbad, near Boppard, where he was subjected to the hydropathic system and regimen, and after the lapse of some time, according to the letters which he wrote to friends in England, he experienced a certain amount of benefit as regards his sufferings, and also in the regaining a degree of suppleness and utility in the smaller joints, the ankylosed condition of the larger ones, forbidding the entertaining any hope as to their improvement.

In the course of time having apparently at least derived some benefit from this mode of treating disease, he entertained a proposition to practise hydropathically, and entered into partnership with a Dr. Schmidt, at Muhlbad accordingly, the care of the English patients devolving on him. Dr. Mayo, however, was not prepared to be so thorough a follower of Preissnitz, as to swear *in verba magistri*; although employing the principles of hydropathy, and enforcing a strict regimen in the cases of disease which came under his notice, he did not restrict himself to that plan only, but availing himself to the full when requisite, of his extensive medical knowledge, he treated disease in accordance with the rules of science, using only those parts of the hydropathic plan, which he considered to be adapted to the especial features of each case, thus acting in his medical capacity scientifically, if we may so use the term, and not empirically. The partnership with Dr. Schmidt did not endure. Dr. Mayo afterwards opened an establishment for himself at Bad-Weilbach, near Mayence, where he enjoyed a considerable share of practice, and lived very happily, until he became afflicted with paralysis, which, by diminishing still further his capacity for resisting the inroads of disease, ultimately led to his decease. The immediate cause of death was mortification of the arm.

Dr. Herbert Mayo was well known in the medicoliterary world as the author of several excellent works. One of his earliest productions was entitled "Anatomical and Physiological Commentaries;" it was published in two parts, (illustrated with engravings), 1822—23. In the first of these he made known his views on the vital principle, and also his experiments on muscular action, and on the influence of the portio dura and the facial branches of the fifth, together with commentaries on Reil's "Essays on the Structure of the Brain." In the second part he continued the last-named subject, and extended his observations to Reil's remarks on the medulla oblongata and the peduncles of the cerebellum, the anterior commissure, the septum lucidum, etc., and on the spinal cord and the nervous system generally. He published also essays on the cerebral nerves, with reference to sensation and voluntary motion; on local action; the structure of horn, hoof, and cuticle; the Hunterian theory of absorption; and also an account of the examination of a body soon after parturition. This work, which is but rarely to be met with, made its appearance in his 26th year. In 1825 he published a useful work called "Course of Dissections;" and, two years later, a magnificent work, in folio, "The Plates of the Brain," a book, as yet, unsurpassed. In 1833 appeared the "Observations on the Injuries and Diseases of the Rectum," a work then much wanted, as there was scarcely a modern work on the diseases, &c., of that bowel, worth notice. In these observations we have a plain, straight-forward account of these diseases, and their mode of cure, illustrated by cases; it shows the practical surgeon throughout. The "Outlines of

Human Pathology" is an octavo volume, full of sound practical information, and may still serve as a useful guide to the surgeon and student in the acquiring a knowledge of disease, and the mode of treating it, although it has now been published many years. Few works of the present day are equal to it in value. The next year brought us the "Outlines of Human Physiology," the fourth edition, long since out of print. All we need say of this work is, that it is an excellent companion to the preceding. In 1840 appeared the second edition of a work "On the Management of the Organs of Digestion;" a treatise on "Syphilis," a republication of lectures which appeared originally in the *London Medical Gazette*; it contains some original views, and will well repay a perusal and attentive study of its pages. Notwithstanding such large and valuable additions to medical literature, Mr. Mayo's pen did not remain idle. In 1842 he published a small work "On the Nervous System and its Functions," in which he recapitulated his own discoveries, and those by Sir Charles Bell and others, on that most important and interesting branch of physiology. The *Medical Gazette* contained also many useful lectures and papers from his pen.

After he had left England, and had given, as he believed, a fair trial to hydropathy, he brought out a work entitled "The Cold Water Cure, its Use and Abuse." This appeared in 1847, and all we shall say of it is, that it is quite out of print. His final publications were made last year; they are,—“On the Truths contained in Popular Superstitions;” and the third edition of his “Philosophy of Living.” The former of these tends to show the peculiar bias of his mind; of the latter, the mere fact that it had reached a third edition is praise enough.

The Government is at last aroused to the imminence of the danger impending over the country, by the dreaded invasion of the fearful epidemic which is committing such devastation on the Continent. Every report received from abroad shows that the present epidemic, so rapidly approaching our shores, has a far higher degree of malignancy, than in the two previous invasions of 1832 and 1849, the ratio of mortality on this occasion being generally above fifty per cent.; and yet up to this time, although the warning note has been previously loudly sounded, nothing (or next to nothing) has been done to place the country in a condition of sanitary improvement, so that the inhabitants may be able to resist its insidious advances. Greater anxiety was manifested on the first occasion, in 1832, than now; but at last, after hearing for months that this disease has been raging in Poland and in Silesia, on finding that the great sea-ports through which a great deal of the commerce of the country is conducted, have become infected, the General Board of Health have so far bestirred themselves as to reappoint Dr. Sutherland and Mr. Grainger, Cholera Medical Inspectors, and to despatch the last-named gentleman to the cholera lands, to inspect, examine, and report upon the disease, instead of staying here to superintend the labours of those who are employed in carrying out the necessary sanitary measures. After remaining idle for three or four years, the Board of Commissioners of Sewers have suddenly resolved to do their little something in the matter. The rapid approach of the cholera seems to have frightened them into work, and they have resolved to apply to Government for the money, to enable them to cover over foul uncovered ditches and sewers, and to remove all other injurious nuisances. If they can succeed in doing this, their labours will be indeed Herculean; for London is a genuine Augean stable, full of filth, foulness, and all uncleanness—personal, general, and moral. In many parts the inhabitants, already decimated by typhus, small-pox, scarlet fever, *et hoc genus omne*, are ripe to be cut down by the cholera sickle. What an awful approach it is upon our rulers, that this disease, now on

its third visitation among us, should find us wallowing in the same amount of filth as at its first advent, and no better prepared to resist its ravages than we were then. When will our rulers learn wisdom, and know that the true happiness and health of the people are in the charge of their governors? The violence of the pestilence is lessening in Warsaw, and in other places in Poland and Silesia, but its giant steps are directed hitherwards. Preparations are being made in Berlin, in expectation of its enemy. Cases have occurred in Vienna. It is raging fiercely in Dantzic. At Magdeburgh and Königsberg many have already perished. And some isolated cases are said to have occurred even in Hamburg. It is pursuing the same route as in its previous visits, and is making about the same stay in each place. We are greatly favoured in being thus warned of its approach long beforehand, but we do nothing to avert its dangers. It might almost be regarded as a natural suicide!

Small-pox continues to prevail in the thrice-doomed island of Jamaica, where it is reported the cholera has again made good its footing. The inhabitants, after two years' peril, and the loss of 40,000 lives, had scarcely a breathing time from the former epidemic, ere the small-pox and measles broke out with great virulence, and destroyed large numbers, and now again they are threatened with the cholera. Surely there must be something radically wrong in the sanitary condition of this beautiful island, for the destruction of human life by epidemic—preventible disease—for the last three or four years, has been enormous and frightful in the extreme, tending almost to the depopulation of the island. At Port-au-Prince, among the free negroes of Hayti, a singular pestilence, causing a “rotting of the stomach,” has been the means of great loss of life. Death ensues in twenty-four hours, if unchecked. At the Havana, they have a combination of the destructive endemics,—to wit, cholera, yellow fever, and small-pox, and so great is the mortality, that out of 120 soldiers in one company, only ten remain; and of one chain-gang of convicts, 109 in number, all but nine have perished.

APPOINTMENT.

William James Moore, Esq., for the last three years Resident Surgeon at the Queen's Hospital, Birmingham, has just been nominated as an Assistant Surgeon in the service of the Honourable East India Company; and it is satisfactory to add that the nomination was procured for him by a friend, in consideration of those personal and professional merits which he had the fullest opportunities of estimating.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, August 26:—William David Adams, Edinburgh; Henry Homer Granger, Skidton, Yorkshire; Thomas Smith, Oxfordshire; Samuel Woodall, Dudley; William Henry Yates, Westbury-on-Tove.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

SOUTH-WESTERN BRANCH.

Mr. Fuge having withdrawn from the Association, Dr. Cookworthy has succeeded him as a member of the Council of the Branch.

W. D. KINGDON, Secretary.

TO CORRESPONDENTS.

Communications have been received from Mr. Bree, M.D. (with *Bath Chronicle*), Mr. Kelson, Mr. Frew (with many thanks), Dr. Bryan, Dr. Meret, Dr. Barker, Mr. Cooke, Dr. Whitehead, Dr. Tunstall, Dr. Davies, Dr. Copeman.

ALLSOPP'S PALE OR BITTER ALE.

IN consequence of the REPORTED ADULTERATION of BITTER BEER, Messrs. SAMUEL ALLSOPP and SONS have received numerous incidental TESTIMONIALS to the excellence, purity, and salutary effects of their ALES. They consider it due to the Medical Profession, who have so long recommended ALLSOPP'S PALE ALE in all cases where dietetic regimen is required, to give publicity to these Testimonials, as a means of disabusing the public mind of any possible prejudice on the subject.

By the following extracts among a number from the most eminent Medical Men, the Profession throughout the country will have the satisfaction of finding their just appreciation of the remedial advantages of ALLSOPP'S PALE ALE amply confirmed by the concurring testimony of the most able Physicians and Surgeons, as well as the most illustrious Chemists of the time :—

FROM BARON LIEBIG,

"The specimens of your PALE ALE sent to me have afforded me another opportunity of confirming its valuable qualities. I am myself an admirer of this beverage, and my own experience enables me to recommend it, in accordance with the opinion of the most eminent English Physicians, as a very agreeable and efficient tonic, and as a general beverage both for the invalid and the robust."—*"Giessen, May 6."*

FROM PROFESSOR GRAHAM, F.R.S., UNIVERSITY COLLEGE, LONDON; AND PROFESSOR HOFMANN, Ph.D., F.R.S., COLLEGE OF CHEMISTRY, LONDON.

"The sifting nature of the chemical examination which the Beers of Messrs. ALLSOPP's manufacture for many months past have been subjected to, fully establishes their incontestable purity. The process of brewing PALE ALE is one in which nothing but Water and the best Malt and Hops of the first quality are used: it is an operation of the greatest delicacy and care, which would be entirely ruined by any tampering with the materials employed."—*"London, April 26."*

FROM THE ANALYTICAL SANITARY COMMISSIONER OF THE "LANCET," MAY 15, 1852.

"From the pure and wholesome nature of the ingredients employed, the moderate proportion of alcohol present, and the very considerable quantity of aromatic anodyne bitter derived from hops contained in these Beers, they tend to preserve the tone and vigour of the stomach, and conduce to the restoration of the health of that organ when in a state of weakness or debility. They resemble, indeed, from their lightness, a *wine of malt*, rather than an ordinary fermented infusion; and it is very satisfactory to find, that a beverage of such general consumption is entirely free from every kind of impurity."

FROM R CHARLES M. CLARKE, BART., PHYSICIAN TO HER LATE MAJESTY THE QUEEN DOWAGER.

"I have frequently recommended BITTER ALE medicinally, and when my home-brewed Ale has been exhausted, I have been supplied with Ale 'from your brewery.'—*"Wiggington Lodge, May 2."*

FROM THOMAS WATSON, M.D.

"In the genuineness and salubrity of PALE ALE and BITTER BEER, as manufactured at Burton, my confidence remains unshaken."—*"Henrietta Street, Cavendish Square, May 5."*

FROM GEORGE BUDD, M.D., SENIOR PHYSICIAN OF KING'S COLLEGE HOSPITAL.

"I did not want any testimony to satisfy me of the perfect purity of the PALE ALE manufactured by you. A close observation of its effects upon myself and upon many others to whom I have prescribed it long ago, convinced me, as such as the most searching chemical analysis could do, that it contains nothing more than malt and hops, and as it is a first-rate beverage."—*"Dover Street, May 1."*

FROM MARSHALL HALL, M.D., F.R.S.

"My confidence in the purity of your PALE ALE remains unshaken, and my opinion of its great value in a dietetic and remedial point of view, is entirely confirmed by long time and experience."—*"Grosvenor Street, April 30."*

FROM BENJAMIN TRAVERS, ESQ., F.R.S.

"I do not hesitate to affirm, that no deleterious substance is employed in ALLSOPP'S PALE ALE and BITTER BEER, and that my confidence in its wholesomeness as a beverage remains unshaken."—*"Green Street, April 30."*

ALLSOPP'S PALE OR BITTER ALE

May be obtained in Casks of all sizes from the BREWERY, BURTON-ON-TRENT; and from the undermentioned BRANCH ESTABLISHMENTS:—

LONDON, at 61, KING WILLIAM STREET,
CITY;
LIVERPOOL, at COOK STREET;
MANCHESTER, at DUCIE PLACE;

DUDLEY, at the ROYAL BREWERY;
GLASGOW, at 115, ST. VINCENT STREET;
DUBLIN, at ULSTER CHAMBERS, DAME STREET;

BIRMINGHAM, at MARKET HALL;

At either of which places a list of respectable parties who supply the Beer in Bottles, (and also in Casks at the same prices as from the Brewery,) may at any time be seen.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

THE SESSION of 1852-3 will commence on **FRIDAY, 1st OCTOBER**, when an **INTRODUCTORY LECTURE** will be given by **J. TURNBULL, M.D.**, Physician to the Infirmary.

WINTER SESSION.

Anatomy, Physiology, and Pathology—Mr. Long, Fellow of the Royal College of Surgeons of England, and Senior-Surgeon to the Dispensaries.
Anatomical Demonstrations and Dissections—Mr. G. Padley.
Chemistry and Pharmacy—R. H. Brett, Ph.D., F.L.S.
Principles and Practice of Physic—Joseph Dickinson, M.A., M.D., Physician to the Infirmary.
Principles and Practice of Surgery—Mr. Cooper, Fellow of the Royal College of Surgeons of England, and Surgeon to the Infirmary.
Clinical Medicine, and Instruction in Morbid Anatomy—J. R. W. Vose, M.D., Physician to the Infirmary; J. Turnbull, M.D., Physician to the Infirmary.
Clinical Surgery, with Instruction in Morbid Anatomy—Mr. Cooper, Fellow of the Royal College of Surgeons of England, and Surgeon to the Infirmary.

SUMMER SESSION.

TO COMMENCE 1ST MAY, 1853.

Materia Medica and Therapeutics—Thos. Inman, M.D.
Botany—I. B. Nevins, M.D., F.B.S.
Midwifery, and Diseases of Women and Children—Mr. Batty.
Medical Jurisprudence—R. H. Brett, Ph.D., F.L.S.; Dr. Inman.
Practical Chemistry—Dr. Brett.
Ophthalmic Medicine and Surgery—R. Hibbert Taylor, M.D.
Clinical Medicine, with Instruction in Morbid Anatomy—Dr. Dickinson.
Clinical Surgery, with Instruction in Morbid Anatomy—Mr. Cooper.

Fees to all the Lectures (including Practical Chemistry) required by the Hall and College, £45, payable in advance.

Examinations will be held annually in all the subjects, and Prizes or Certificates of Honor awarded according to proficiency.

A Gold Medal, of the value of £10. 10s., will be awarded annually to the Student who distinguishes himself most in a general examination on all subjects taught at the School. The Committee of the Infirmary will, in addition, give to the Medallist Six Months' Free Residence, Dressership, and Clerkship, in the Infirmary, with the Title of Liverpool Royal Infirmary Medical Scholar. In case the Medal is taken by a Resident Pupil, six months' payment will be returned to him.

HOSPITAL PRACTICE.

Students are admitted to the Medical and Surgical Practice of the Liverpool Infirmary from 10 A.M. to 1 P.M., daily. The Certificates are received by the University of London, the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Worshipful Society of Apothecaries.

The Liverpool Royal Infirmary contains 226 Beds, Operating and Lecture Theatres; and a good Museum of Healthy and Morbid Anatomy is attached to the School.

Six Dressers and Six Clinical Clerks will be elected quarterly by selection and examination from amongst the House and Out-Pupils of the Infirmary, from the Students attending the School in their Second or Third Session, and from all Medical Pupils who have entered

on their third year of professional education. The Office will be tenable for two successive periods. Pupils of the Infirmary are admitted to learn Pharmacy in the shop for six months. Clinical wards have been set aside for select cases, and a Clinical Prize instituted for annual competition.

FEES FOR MEDICAL & SURGICAL PRACTICE.

For the first year, £18. 18s.; for the Second, £12. 12s.; for the Third, £10. 10s.; for Three Years, £36. 15s. No additional fees whatever.

Apprentices are admitted for five years, to reside and board in the house, for 60 guineas per annum; and for one, two, or three years, upon payments of 70, 130, or 190 guineas. Such sums to include Library Fees, but not Hospital Practice.

For further particulars apply to Mr. LOWNDES, at the Infirmary.

Tickets for the Lectures to be procured from the Secretary, Dr. INMAN, and counter-signed by the respective Lecturers.

REGISTRATION.

The Register of Tickets of Admission to Lectures or Hospital Practice is open from October 1st to 21st, 1852, and from May 1st to 14th, 1853, the latter day inclusive. Application to be made, and the Tickets brought, to Dr. INMAN, at his residence, 16, Rodney Street, any morning between nine and eleven o'clock.

Liverpool Royal Infirmary,
June 10th, 1852.

LEEDS SCHOOL OF MEDICINE.

TWENTY-SECOND SESSION, 1852-53.

THE WINTER SESSION will commence on **MONDAY, OCTOBER 4th, 1852**, when **THOMAS NUNNELEY, Esq., F.R.C.S.E.**, President for the ensuing year, will deliver the **INTRODUCTORY LECTURE**, at twelve o'clock.

Anatomy, Physiology, and Pathology—Mr. Nunneley, Mr. Ikin, and Mr. S. Hey.
Descriptive Anatomy—Mr. Price, Mr. Wm. Nicholson Price, and Mr. C. G. Wheelhouse.
Principles and Practice of Surgery—Mr. Hey and Mr. Garlick.
Chemistry—Mr. Morley and Mr. Scattergood.
Principles and Practice of Physic—Dr. Chadwick and Dr. Heaton.

SUMMER SESSION.

Materia Medica and Therapeutics—Dr. Clark.
Midwifery and Diseases of Women and Children—Mr. Smith and Mr. Braithwaite.
Forensic Medicine—Dr. Pyemont Smith.
Botany—Dr. Heaton.
Practical Chemistry—Mr. Scattergood.
Operative Surgery.

*** Application for Tickets may be made to Mr. GARLICK, 21, Park Row.

N.B.—Attendance on the above Lectures will confer the same qualification for examination as is obtained in the Medical Schools of London.

Clinical Lectures will be given at the General Infirmary on Medical Cases by Dr. CHADWICK and Dr. HEATON. On Surgical Cases, at the General Infirmary, by Mr. SMITH, Mr. T. P. TEALE, and Mr. SAMUEL HEY. On Ophthalmic and Aural Practice, at the Eye and Ear Infirmary, by Mr. NUNNELEY. Medical Libraries are connected both with the School and the Infirmary.

LECTURES ON THE DISEASES OF CHILDREN,

DELIVERED IN THE

Chatham Street School of Medicine, Manchester.

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Vienna, etc.

LECTURE XIV.

Bilious Fever; a summer disease, rare in children.

Characteristics. Head symptoms. Combination with other fevers. Valuing of bilious vomiting. Complications—meningitis, pneumonia, hepatitis. Cause and disposition. Prognosis—transitions, issues. Treatment—emetics, purgatives, and antibilious indication.

GENTLEMEN,—*Bilious fever*, an acute disease, spread over all Europe, but more common and vehement in the southern countries, and in hot summer, time, seldom occurs before the eighth year, or at least not strongly characterised before that age.

This fever consists not in a mere functional derangement of the liver—a frequent complication of many acute diseases, but apparently in a chemical alteration of the blood, by the influence of heat and rarefied atmosphere upon our respiratory organs and skin. The effect of this seems to be overcarbonisation, or overvenosity of the blood, of which superabundant bilious secretion, or accumulation of bilious elements in the liver, is but a consequence. *Post-mortem* examination confirms the same. I have dissected patients, amongst whom some were children, who died of this fever, and in whom no structural alterations could be detected, except those of accidental complications, but in whom, besides a great quantity of bile in the gall-bladder and liver, there was a striking abundance of dark venous blood in the abdominal and other organs. In southern Europe, in Italy, Hungary, and Austria, it is a frequent epidemic of *hot summers*, along with dysentery and summer cholera. In this country (Great Britain) it appears to be rarer, and less violent, though last week I saw two children strongly affected. Now, this acute bilious dyscrasy, in its full development, I seldom meet with before the eighth year, (just like that of typhus,) and in very few cases, and not so clearly developed, before the second year of life.

One case I have quoted in my Hungarian work, of which the history is recorded in the case-book of the Children's Hospital of Pesth, under the number 1084, of the year 1844; it concerns a child only nineteen months' old, the youngest I ever saw. Neither in this, nor in any other instance of a young child, however, could we determine the diagnosis before the third or fourth day after the beginning of the fever. Between the second and fourth year I have seen some more characteristic cases. In almost all of them, for the first day or two, bilious fever approaches the

description we gave of the hypersthenic fever, from which we may be able to distinguish it towards the third or fourth day, by the dark-brown, greenish, apparently bilious quality of the intestinal discharge, or the intense yellow, or green, of the vomited liquids, if the one or the other came either naturally or by medicine. The skin is dryer than in other fevers, except the gastric and typhoid. Sooner than the third day bilious discharges have much less distinctive signification, because the case might yet become, at that time, scarlatina. With measles and small-pox you will less easily confound it, when you reflect that bilious fever offers a greater dryness of the skin than the two latter, before the eruption comes out. A careful examination of the epigastric and right hypochondriac regions, verifies a tumid state of the liver, along with a more or less visible yellow cover of the tongue, though never so thick as in adults: all this will scarcely be discoverable before the fourth day. The urine leaves a brownish or yellow stain. A yellowish hue in the face, about the cheeks, mouth, or the conjunctiva, if present, serves us as an excellent guide; but this is seldom the case, and scarcely ever before the third day.

We see of what value in this fever are the words of an adult patient, who tells us about the bitter taste in his mouth, and some sensation in the region of the liver, all of which are wanting in young children. The want of these subjective symptoms leads to many a mischievous mistake, because the head of the child affected with bilious fever, presents very alarming symptoms. We know what violent kind of headache grown-up persons complain of in these cases. It can cause mischief to the little patient, if overlooking the tense state of the right hypochondrium, we would apply leeches to the head, instead of giving an emetic—mischief both positive and negative.

The diagnosis seems to be difficult also, inasmuch as acute bilious dyscrasy frequently combines with or joins scarlet fever, more seldom measles, typhus, and almost all kinds of continued fever. But this difficulty is but apparent. Your purpose will be to detect the bilious state in the child, if present, and then act against it, whatever name you may give the fever.

As to the diagnostic value of *bilious vomiting*, if it be the symptom of an affection of the brain, or of an exanthema to come, it is far less in degree and less constantly connected with such fulness of the epigastrium, and yellowish appearance of the tongue, than if it comes from bilious fever.

But bilious fever does not exclude the possibility of the development of meningitis during its course. It also sometimes engenders pneumonia, more frequently hepatitis or enteritis.

Concerning *prognosis*, it is certain that acute bilious dyscrasy attacks more frequently and more dangerously children of a full plethoric constitution, with dark hair. The general bilious character of a constitution, in addition to the degree of the fever, makes the latter always proportionally more severe.

In hot summer this fever becomes very dangerous. It goes sometimes along with summer cholera. I have

seen instances, when a child under a sudden attack of high fever, was seized by bilious vomiting and similar diarrhoea (the evacuated liquids of real cholera have not that character), with an excessive appearance of languor, almost threatening death: when an hour after that happened, fever was gone, and the little sufferer at once relieved to cheerfulness. This again shows how dangerous it might be to directly check bilious evacuations. If, however, this crisis does not appear at an early stage, the effect will scarcely be so complete. The bilious dyscrasy once established, runs a longer course, for several days, even weeks, towards recovery. I have seen it in some instances of young children, to come on suddenly, when, as soon as the bilious aspect appeared, the hypersthenic form of reaction declined into astheny, ending fatally under profuse bilious diarrhoea in three or four days. I have seen it sometimes pass into a kind of low remittent, or gastric form, to be spoken of on a further occasion.

The transition of bilious fever into icterus, as in adults, I do not remember to have seen in young children. There is another transition: that into bilious dysentery, which, though fever may sometimes considerably decrease in such case, still forms a very dangerous affection for the tender age. The extraordinary heat which we have here just at present, (July, 1852,) proves also in this country as productive of bilious affections, though certainly they are more violent in Italy or Hungary.

The *treatment* consists of emetics and purgatives, according to directions given, when we spoke on febrile gastric disorder, and in the use of acids against hypercarbonization and bile. The emetic, the sooner the better; but if the child is above three or four years, even the third or fourth day of it will allow yet the use of the emetic, whilst children under two years, will before that time have fallen into astheny, and no more admit that remedy.

Amongst purgatives, whenever the skin is very hot and dry, and the dryness of the mouth indicates a similar state of the gastric mucous membrane, in general in very high fever, I prefer the liquid ones to others, *f. e.*, from one ounce and a half to two ounces of simple infusion of senna, with two to three drachms of sal. sedlitz; under other circumstances, however, one or two full doses of calomel may be useful.

The *antibilious indication* I use to fulfil by the following:—R. Acet. Rub. Idæi, dr. ij.; Aquæ Dest. Simp., oz. ij.; Acidi Tartarici, scr. ss.—gr. xv.; Syrup. Rub. Idæi, vel. Citr., dr. ij. Every hour or two one or two teaspoonfuls. As to the treatment of hepatitis, pneumonia, meningitis, or other complication, it is too well known to be mentioned in this place, and must be applied in stronger or more moderate measure, according to the degree of those local affections, and the stage of fever; but it can scarcely be inculcated too much to the young practitioner, that *if liver and gall-bladder are turgid with bile, in vain we subtract blood from the head, lungs or liver, and in vain we order "antibilious" medicines; the emetic alone can lay the foundation of successful treatment in this case.*

ON THE DIAGNOSIS OF CHRONIC OVARIAN TUMOURS.

By E. J. TILT, M.D.,

Senior Physician to the Farringdon General Dispensary and Lying-in Charity, and to the Paddington Free Dispensary for Diseases of Women and Children.

"Hydrops ovariorum ut plurimum steriles annosque mulieres occupat difficulter cognoscitur et vix sine sectio cadavere."—Boerhaave (*Aph.* 1293.)

(i) *The Impregnated Womb may be mistaken for an Ovarian Tumour.*

NOTWITHSTANDING the greater degree of perfection of our means of diagnosis, our knowledge is still so imperfect that the most eminent practitioners often fall into erroneous diagnosis.

Cases.—M. Tavignot relates that a country doctor in France was consulted by a girl for an abdominal swelling, which she persisted in denying the possibility of being physiological. Thus led astray, he, with an inexcusable precipitation, punctured what he supposed to be an ovarian cyst. Premature labour brought from the womb an eight-months still-born child, and the mother died three months after.

Dr. Corfe in his lectures, (*Medical Times*, July 15,) states:—"I knew of two circumstances in the country where the patients have been tapped for supposed dropsy, and the *post-mortem* examination brought to light that they were both advanced in pregnancy." But such cases are not confined to country practitioners, Professor Murphy, whose well-earned reputation cannot suffer from the avowal of a mistake, informs us that in two cases he had mistaken pregnancy for ovarian dropsy. Mr. Phillips told us that, in a case upon which he was called in consultation, (with two of the most eminent physician-accoucheurs in town,) the tumour had existed eleven months. The two obstetricians said it was ovarian, but Mr. Phillips thought it pregnancy and advised the husband to wait as women were often wrong in their calculations; and some time after the lady was confined. We also, once made a fatal mistake of this description, and record it in order that others may seek for and know how to wait for the signs by which the error may be avoided.

Case.—In June, 1849, we were consulted by the wife of an officer, and at first sight were struck with the emaciated appearance and care-worn expression, so characteristic of an advanced stage of ovarian growths. The patient was 40, and had been married nine years without having been pregnant. Some months previously and after derangement and suspension of the monthly function, a swelling of the abdomen made her hope that she was in the family way, and a month before calling upon us she had consulted Dr. Mayo, of Winchester, who after a careful examination, pronounced her case to be one of ovarian dropsy. Feeling still confident that she was pregnant she came to town.

From a careful examination of the womb and breasts, and after seeking in vain for the sound of the foetal

heart over the tumour, we pronounced her to be suffering from an ovarian tumour; ordered an iodine treatment, to be followed out by her medical attendant, and an abdominal bandage to be worn. We heard nothing more of the patient until six months after, when her husband wrote to inform us that she had been delivered of a full-grown male child (still born) at exactly nine months after she had been persuaded that she was pregnant, and six months after her visit to town. We know of several instances wherein a successful effort of procreation towards the decline of life was considered to be ovarian dropsy, and of the patients being given up to nature, who brought about a radical cure after the tumour had been retained nine months in the womb.

(i) *Ovarian Tumours are sometimes mistaken for Pregnancy.*

This error of diagnosis is no less frequent than the one previously noticed, but more fortunate, as it presents the intempestive or fatal interference of art. All who have written on ovarian dropsy, have related cases of women in whom that complaint has been considered pregnancy, both by the patients themselves and their medical attendants. Madame Boivin, in her valuable Memoir ("Sur une des causes frequentes de l'avortement") has enumerated nine very interesting cases of this description which occurred in her practice, and in some of them nothing could dissuade the patients from their conviction. The strong desire for progeny, the arrest of menstruation, the appearance of mammary symptoms, and the assurance on the part of the patient, who has already borne children, that she feels the child; such are the grounds which also lead astray the medical man, particularly if he feel a regularly round tumour, rising, as does the womb, from the pubes to the umbilicus, instead of descending from the umbilicus to the pubes, as do many other tumours. Some have attempted suicide, under the conviction that the natural consequences of unlawful connection were becoming manifest; while others, who under the sanctity of the marriage tie, could contemplate any amount of abdominal swelling with the same feelings of pride as those ascribed by Tacitus to Agrippina, could not bring themselves to relinquish their long cherished hopes of progeny. If the frequency of this mistake be as great as we have said—if falling into such an error of diagnosis either causes the death of the patient, or unbecomingly fosters her delusions, it behoves us carefully to inquire how such an error may be avoided.

In the first place let the practitioner make up his mind to consider every woman as pregnant who may consult him for an abdominal enlargement, however old the patient may be, or of however high the rank, or spotless the virtue of the unmarried. Let him ask himself—"Is not this a case of pregnancy?" and let the idea of pregnancy be torn away from him by a most rigorous investigation of all the phenomena of the tumour. By so doing, he will avoid the risk of committing manslaughter. But if, on the contrary, he prescribes limits to nature, and says,—"Such a lady has

been so long sterile, that if any abdominal swelling occur, it must be morbid;" or, Miss — is so high-born, so well bred," he is on the road of discredit and dishonour to himself and his profession. After this word of advice we shall attempt to point out how it is possible to avoid mistaking uterine and ovarian tumours.

Both tumours rise from the pelvis, as we have seen when treating of fibrous tumours of the uterus. And we then mentioned, that the only way of detecting one from the other is, by using the uterine sound; but when reasoning on the hypothesis of pregnancy, the use of this instrument is forbidden, as it would bring on abortion. And when we remember having been told by an eminent obstetric physician that, suspecting a tumour to be ovarian, he had once passed the uterine sound into the uterus, broke the membranes, and produced abortion, we cannot but tremble lest, in the hands of the incautious, this instrument should be an instrument of mischief.

We must take an extreme case, for if a right diagnosis can be obtained in an extreme case, it can in any other. We will suppose the case to be either one of four months' pregnancy, or else an ovarian swelling. The two tumours may be said to have the same seat. We will admit that the physiological softening of the neck of the womb may be imitated by the softened patulous os uteri, when under the long-continued influence of ovarian irritation. Both ovarian and uterine tumours may give rise to the same morning sickness, to the same mammary symptoms, and to amenorrhœa. In both cases there may be a more livid colour of the vaginal mucous membrane. Both patients may feel what they suppose to be the movements of the child; and in both cases the ear applied to the tumour can only detect a *bruit de souffle* when the tumour presses upon the iliac artery, but there is no sound of the fetal heart.

It would seem that there could be little possibility of mistake when, in a married woman for instance, the irregular, scanty, or suppressed catamenia coincide with peculiar or depraved longings, with morning sickness, pains in the breasts, darkening of the circle surrounding the nipple, and a beginning of lacteal secretion, especially if these symptoms, occurring in the midst of health, coincide with a swelling which rises from the cavity of the pelvis.

It will be said, that in the third or fourth month of pregnancy, the neck of the womb will present, to any tolerably experienced practitioner, evident proofs of pregnancy, in the more or less complete spreading of its external orifice, in the kind of œdematous swelling of the lips of the os uteri, in the slight softening of the tissue of the womb itself, and in the regular development of its inferior segment, which seems to form one with the base of the neck of the womb, and to be itself the tumour. All this is very true, but the neck of the womb may be displaced by some pelvic ovarian tumour which may take the position it usually occupies in the first months of pregnancy. Then, again, the length and the form of the neck of the womb, and of its orifice, are far from being the same in all women; and

when enlarged by previous confinements, and patulous from granular ulceration, and from a low type of inflammation, it may afford reasons for confounding it with the physiological softening of the same organ during pregnancy. The situation also of the tumour gives us no certain indication, for we have seen ovarian tumours central from the first; and the pregnant womb, on the contrary, may develop itself on one or the other sides of the pelvis, a remarkable instance of which we lately saw in a patient who had for some time been treated *homœopathically* for an ovarian tumour. When lying on her back the tumour seemed to spring from the right side, where the patient suffered extremely, and on assuming the sitting posture, the whole of the pregnant womb was seen lodged on the right side—a singular appearance, which had, no doubt, caused her pregnancy to be mistaken for an ovarian tumour.

With regard to the arrest of the catamenia, this is common in pregnancy, but very rare in ovarian tumours, unless both ovaries are affected, and not always then. It is sometimes profuse in the beginning, but more generally scanty, and often irregular. So far our own experience is confirmed by that of Dr. Clay, who thus writes to us:—"Of the numerous cases which have come under my observation, I have not in my remembrance any case of ovarian disease where menstruation was truly normal. There is in *all* more or less irregularity, the chief features scanty at long periods, somewhat painful, and not of good colour; I have seldom found it entirely absent, except in cases where both ovaries have afterwards been proved to be extensively implicated. I have *YET* to see perfect regularity of menstruation where there is a decided ovarian enlargement. What I mean by perfect regularity is,—in time, quantity, and quality." These assertions are fully borne out by those of one of the best writers on the subject. Caseau says:—"Derangements of the uterine functions sometimes precede every other symptom and all appearance of disease. Normal menstruation, generally speaking, sometimes becomes irregular in time and in quantity, being sometimes scanty, sometimes profuse. Successive miscarriage, accompanied by bleedings, even sometimes seem to have preceded the disease, or rather to have coincided with its first appearance." On the other hand, Mr. Samuel Lane informs us:—"That in nine cases out of ten which have come under his notice, the menstrual discharge was not interrupted by the occurrence of ovarian dropsy." And Meisner confirms this assertion by giving as the result of his experience, that the absence of menstruation is no criterion of ovarian dropsy. He remarks, however, "that should it be absent at an early stage of the disease, hysterical symptoms supervene."

It is sufficiently proved, that the total absence of the catamenia, which is the rule in pregnancy, is the exception in ovarian disease, only occurring, as Dr. Seymour first pointed out, when both ovaries are affected, and not always then, as proved by the experience of Madame Boivin and our own. Dr. F. Bird even affirms, that in one of his cases the catamenia

appeared after the extraction of both ovaries. Except, therefore, in extreme cases, the state of the catamenial flow will only help to a diagnosis without positively indicating it.

Pregnancy and ovarian growths wake up the same sympathetic effects in the breasts, which become swollen, firmer, are often the seat of darting pains, the nipple becoming tumid, surrounded by a dark circle, and even milky fluid may be secreted, without there having been any previous pregnancy. The fact has been doubted by some authors, and we believe by Caseau, but the following fact, to which others might be added, proves that it may occur:—

Case.—In a case of ovarian tumour, says Mr. Jeafferson, not only did the breasts enlarge, and secrete milk, but the woman was conscious of the movements of the child, which after a time suddenly ceased, and then the breasts became flaccid. The patient supposing the child was dead, consulted me, and both ovaries were found diseased. The one filled the abdomen, the other was jammed into the pelvis. No trace of conception was found anywhere.

Meisner says, that these consensual affections of the heart are more apt to supervene when menstruation leaves off at an early stage of the disease; but these mammary symptoms do not persist as they do in pregnancy, on the contrary, they generally disappear after a few weeks, although the primary affection may continue its progress. The persistence of mammary symptoms may, therefore, help us to diagnose pregnancy. In obscure cases, however, there is no possibility of arriving at a positive diagnosis, and we must wait—wait until the catamenia reappear regularly in ovarian dropsy, and the mammary sympathies diminish, or vanish completely; while, if the patient be pregnant, the catamenia will not return, and the mammary symptoms will increase, or remain stationary. Wait until the sixth month, when it will be no longer difficult to decide whether the tumour be morbid or physiological; for in the first case, with the exception of an increase in size, the tumour remains as it has been all along; while in the second, if the foetus be alive, there is—1st, active movement on the part of the child; 2nd, its passive movement or *ballotement*; and, 3rd, the double beat of the foetal heart. These three signs often coexist, and the last is the most important.

1st. With regard to the so-called movements of the child, whether they be produced, if by the active exertion of the child, as we still believe, or by the peristaltic motion of the womb accustoming itself to an important function, as has been lately advanced, it is equally difficult to understand how women who have had children, and afterwards become affected with an ovarian tumour, can consider the abdominal sensations caused by an inert tumour and those of a living child, to be exactly similar, for in an ovarian tumour the muscular fibres of the unimpregnated womb could not, by their contraction, give rise to such sensations. However inexplicable the mistake may be, it has so

often occurred that unless the medical practitioner himself has distinctly felt the child's movements, the patient doing so would give no certainty to the diagnosis of pregnancy.

2nd. The ballottement, on the contrary, must bring to the mind of the practitioner who experiences that sensation, the idea of a free body moving in the distended womb; whereas, if the tumour be ovarian the shock will not be felt; but we must also bear in mind that the sensation of ballottement is not always to be obtained.

3rd. The sound of the foetal heart. When the ear, by means of the stethoscope, explores the surface of an abdominal tumour towards its inferior portion, more particularly in the vicinity of each inguinal region, a bellows' sound is heard; it is a *bruit de soufflet*, and owes its origin to the pressure of the tumour on the large arteries situated beneath. This sound may be produced by any sort of tumour pressing on these arteries; but when the abdomen of a pregnant woman is examined in the same way, something similar is heard, which the tutored ear very soon distinguishes as the placental murmur, caused by the passage of the blood through the placental vascular ramifications. But this sound cannot be relied upon as a sufficient proof, because the bruit of the enlarged vessels of an ovarian tumour has been sometimes mistaken for the placental murmur; as in the case of a patient of Dr. Fleetwood Churchill.* The danger of relying upon that sound is also well shown in the following instance, related by Brichteau, of a woman in whom, with the other signs of pregnancy, there was the *bruit de soufflet*, which was thought to be that of the placenta. An ovarian conception was diagnosed. Gastrotomy was performed, and there was found to have been no pregnancy. The patient died six days afterwards.

The distinct perception of the tic-tac of the foetal heart is, on the contrary, the incontestable proof of pregnancy. We have never found any sound to imitate it, and in this one instance we should be tempted to reserve the old adage—"signum unum, signum nullum," for it enables us to affirm the existence of a living child. In thus strongly expressing our own convictions we do not pretend that even after the sixth month it can always be detected. The inquirer may be placed in unfavourable circumstances which may render it necessary to repeat his examination several times before he hears the sound, but it has never yet occurred to ourselves to make a careful and repeated search after this sound in women six months gone with child, without detecting it. We are aware that others do not attach the same importance to this. Thus at a discussion on the diagnosis of ovarian disease, Professor Murphy is reported to have said that the transmission of the sound of the heart of the patient by a solid ovarian tumour might be mistaken for the sound of the foetal heart, and lead to the belief of pregnancy where none exists. Mr. Drewitt supported the same views, but we cannot understand how the

sound of the patient's heart, beating sixty times in the minute, can be mistaken for that of the foetal heart, beating 120 in the same space of time, and in the belief that such a sound can be confounded with no other. Caseau says:—"I can affirm that for the last five or six years I have not met with a woman in the family way (the child being alive) without hearing the sound of the foetal heart after the first six months of pregnancy," and we so fully agree with him, that if after repeated examinations we could not detect that sound we should have no hesitation in affirming that the woman is not pregnant, or that if she had been so, the child is dead.

If the child be dead, the difficulty of diagnosis is thereby considerably increased. Then we must make the most of the information afforded by the examination of the neck of the uterus which will present those modifications which are generally sufficient to denote pregnancy. The sensation of ballottement may still be obtained. Owing to the resiliency of the uterine parietes it will be often possible to detect through them eminences corresponding to the head and limbs of the child.

Should the pregnancy be extra-uterine, the sound of the foetal heart will give the same undeniable evidence of the child's existence; but the case already related will teach the surgeon not to ground so important an operation as gastrotomy on the audition of a placental murmur, which may be imitated by the *bruit de souffle* of the enlarged vessels of the ovarian tumour, or by the arterial souffle of the compressed iliac artery.

If the child be dead, we agree with Bluff, that there will be no possibility in distinguishing an extra-uterine pregnancy from an ovarian tumour, because both tumours have nearly the same seat, and the difficulty would be increased in the case of dropsy, or if the pregnancy be tubal. The history of the case, the mother's distinct perception of the child's movements, the flaccidity of the breasts, the arrest in the progress of the tumour—which has become harder, and presents eminences resembling the salient points of bones, must guide the sagacious practitioner.

Lastly, it must be borne in mind, that during the progress of ovarian disease the patient may be repeatedly pregnant, that the two may coincide, and that the certainty of an ovarian tumour in one part of the abdomen must not cause the attendant to disbelieve the existence of pregnant womb in another part of the same cavity. Such mistake has been fatal in several of the cases operated upon, the operation having brought on abortion. By careful examination in this case two tumours will be found, or at least two portions of what may seem to be one tumour. In the one, when it is sufficiently developed, the sound of a foetal heart will be heard, but nothing similar in the other portion. When there is the slightest doubt, let the attendant follow the philosophic precept and abstain from treatment.

In concluding this important subject we may add, that the frequent errors which are committed are the result of the hasty and careless investigation of the medical man into the cases of women already pro-

* Outlines of the Principal Diseases of Woman, t. iv., p. 364.

nounced to be affected with ovarian disease, and that if we were perfectly unaffected by what Dr. ——— and Mr. ——— may have thought of the case, and were to conduct our own inquiries (repeating them sufficiently often) upon the principles we have laid down, there would be but few cases wherein it would be impossible to give a correct diagnosis.

To the junior members of the profession we shall again say, "learn to wait." The medical practitioner must oftener be a Fabius than a Marcellus. No doubt he sometimes wants the eagle glance of the general on the battle field, to know how to break the force of the disease by a sudden attack, but more frequently will he find the prudence of keeping to the hills and dodging the enemy. In beginning practice we are apt to give decided opinions; to this we are prompted by the impulsive energy of youth, and by the fear of being accused of ignorance if we do not give a decided answer. Thus we are persuaded to an erroneous diagnosis which we should not have given if we had well examined and thought over the case;—an error of diagnosis which may compromise the reputation of the man of talent, and which no future professional success can wholly obliterate from the minds of the public.

11, York Street, Portman Square.

GALLIC ACID IN HÆMOPTYSIS.

By WILLIAM BAYES, M.D.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—The invitation given forth in the last number of your journal to your subscribers, "to put their shoulders to the wheel," induces me to forward you the history of a case which has very recently occurred to my notice, and which, showing as it does the great value of gallic acid as a therapeutic agent, and the large doses with which it may be given with safety, may possibly appear to possess some interest to your numerous readers.

I am, Sir, yours obediently,

W. BAYES, M.D.

Marine Square, Brighton.

Mr. R., a gentleman of bilious temperament and thin conformation, called upon me (professionally) on Sunday, the 6th of June. Before he had recovered from the fatigue of walking to my house, and while his wife was giving me a slight sketch of his ailments, he gave a painful evidence of his state by a fit of coughing, accompanied by some slight hæmoptysis, perhaps as much as two or three tablespoonfuls. After recovering him from the faintness which ensued, and quieting the mental anxiety and excitement which this induced, I sent him to his house, (which was near at hand,) with orders to be put to bed at once, and to be kept per-

fectly quiet. On following him to his house, I heard from his wife that he had been for years subject to attacks of (what they believed to be) bronchitis;—that he was at this time threatened with jaundice;—that four years since Dr. Ramadge had pronounced him incurably consumptive;—that, not being satisfied with this opinion they had consulted Dr. Addison, who had reported the same;—that their present London physician had, however, told them that it was merely bronchitis;—that, after a severe attack, which had been accompanied by profuse expectoration, by night sweats, and by hectic fever, he had been advised to visit Brighton;—that he had been in Brighton two weeks, and had apparently much improved, when he imprudently had walked to the top of the Downs;—that the fatigue attending this exertion had caused him to expectorate blood five or six times;—that this had frightened them, and that they had continued their walk to my house, to ask whether it would be safe to return at once to London;—and that the excitement attendant upon this last imprudence had produced the hæmoptysis before-mentioned.

In the highly nervous and excitable condition in which I found Mr. R., (he had been shedding tears like an hysterical female,) I did not deem it prudent to make a very lengthened or particular stethoscopical examination of the lungs, especially as the hæmoptysis had much diminished since he had assumed the recumbent position. I found, however, that they were extensively diseased, and that there was evidence of subacute inflammation in the lower and back part of the left lung. His skin and face were yellow, and dusky-looking; tongue deeply furred; breath very offensive; pulse 95, rather full, yet jerking and tremulous; skin felt harsh and rough; bowels confined, and for several months he had never had proper action from them, generally scarcely more passed daily than the size of two or three almonds; urine abundant, and he said "it smells quite beautiful, almost as good as a scent." On examination I found it diabetic, although in quantity it was not very much increased, probably not more than six or seven pints daily. The only pain he felt was a dull aching across the loins, and occasionally more severe at the lower and back portion of the left lung. The colour of the expectoration was bright and florid.

I first ordered him a few grains of sulphate of magnesia and sulphuric acid, in infusion of roses, and in twenty-four hours, the hæmoptysis having almost ceased, I gave him three tablespoonfuls of lemon-juice, to be continued every two hours. Under this treatment all the symptoms of subacute inflammatory action subsided, the pulse diminished in frequency, (to 68,) the pain in the side disappeared, the tongue cleared itself, the night sweats became greatly decreased, and in three days ceased altogether. What most of all pleased me was, that the bowels acted freely, and the alvine secretions were well coloured with bile. The patient himself seemed astonished with the change, saying, that his bowels had not acted so well or so comfortably for years. The urine, so far from increasing in quantity, diminished considerably, and Mr. R. was rapidly gaining

strength, and apparently health, his skin losing its dusky yellow tinge, and becoming clear, and even slightly coloured.

I do not ever remember to have seen so rapid a change for the better in six days, but, on the 12th of June, I was as much grieved as astonished to see my patient walk into my consulting room, leaning upon the arm of his wife. Before, however, I had time to express my displeasure, the poor gentleman sunk into my chair, and the hæmoptysis returned, worse than at the first. Every fifth or sixth inspiration brought on the cough, and every cough was followed by sputa of frothy florid blood. I was seriously alarmed for him, and as soon as possible had him conveyed home, and laid upon the sofa, with the strictest injunctions that he should neither be allowed to speak or to move. I ordered him five grains of gallic acid every second hour, and was pleased to see that the hæmoptysis gradually diminished. He probably had lost half a pint of blood between twelve o'clock at noon—when he called upon me, and nine at night, the intervals between each expectoration being, at the latter hour, about twenty minutes, and the colour still florid, although somewhat less bright. At a quarter past eleven o'clock the same night I was summoned, hurriedly. In undressing the patient, the hæmorrhage had a third time recurred. His breathing was now hurried, every inspiration brought on a cough, and every cough brought up bright arterial-looking blood. He was becoming faint and livid-looking when I arrived, and I really was afraid lest he should have been suffocated. The air passing through the blood already in his throat produced a gurgling sound, which alarmed his wife, to whom it sounded like the "death rattle." I now took a drachm of gallic acid, put it into a six-ounce bottle, dissolved it in hot water, and added rather more than a tablespoonful of brandy. I cooled this mixture in some ice which was in the room, and gave Mr. R. a dessert spoonful of it every three minutes. The pulse, which could not be felt at the wrist, recovered slightly after the third dose. At the end of half an hour the face became less livid, and he seemed much revived; I, however, continued the gallic acid every five minutes until the end of the first hour, and afterwards every ten minutes until nearly two hours had elapsed, when, to my great joy, the expectoration became perfectly inky. After the first inky expectoration the breathing became greatly relieved, and the patient fell into a quiet doze. He had taken the first drachm of gallic acid in one hour and fifty minutes. I then mixed a second drachm, in the same manner as the first, and gave him a tablespoonful of the mixture at half-past one o'clock, after which he fell asleep soundly; I then left him, with orders that the gallic acid should be given him, in five-grain doses, every hour, for six hours, while he was awake, or to be repeated every ten minutes if the hæmoptysis were to recur. On calling next morning I found he had expectorated but twice, and the sputa were perfectly inky. I kept him under the influence of the gallic acid for three days, gradually diminishing the frequency of the dose. At the end of this time, as he had neither cough nor expectoration, I

changed his medicine to the infusion of roses and sulphate of magnesia, and ordered him also to take five-drop doses of creasote, three times a day, upon sugar; he now went on steadily getting well. I found it rather difficult to prevent his committing indiscretions in exercise and in diet, and therefore curbed him a little, by giving him minute doses of tartarized antimony; and upon the 26th, or fourteen days after his severe attack, he was so far recovered, and had for some days borne exercise in the open air so well, that I allowed him to go home again to London, indeed for the last three days I could scarce persuade him that he was an invalid.

Perhaps one of the most satisfactory results of the large doses of gallic acid, was the entire disappearance of the diabetes, and the simultaneous reappearance of bile and sufficient stools. Another point worthy of notice was, that the patient weighed precisely the same upon the day he left Brighton as he had done one month previously.

There is yet a third point to which I would direct the attention of the reader,—that the dyspnœa was almost completely relieved as soon as the system was well saturated with the gallic acid. The difficulty of breathing was no doubt caused by the gorged state of the vessels of the lungs, which was relieved by the powerful astringent acting upon them from within.

ON MAMMARY ABSCESS.

By ALEX. H. PATERSON, Esq., ALTRINCHAM.

SEVERAL London surgeons have mentioned that boils, carbuncles, and similar diseases have been very prevalent in the metropolis during the last few months.

These diseases have not been confined to London, but have spread, I believe throughout the country, and in this neighbourhood I have noticed inflammation and suppuration of the breast to be unusually frequent after confinement, in females of all classes. In most of the cases I have seen there has been no cause assigned for an attack of fever, which commonly set in a week or fortnight after delivery, was in many cases very severe and even dangerous, typhoid in character, with disordered secretions and diarrhœa. This was followed by inflammation in one and sometimes in both breasts, terminating in abscess.

Burns and Ryan, in their works on midwifery, tell us that this complaint is very easily induced, and very difficult to check. And we know from experience, that the loose cellular tissue of the gland favours the formation of troublesome sinuses, which give great pain, are very long in healing, and seriously affect the strength. The skin is here thick and loosely attached, and the subcutaneous tissues thickened, pass into a state of sub-acute or chronic inflammation, and remain indolent and painful for a long time. Not unfrequently abscess succeeds abscess, and sinus unites with sinus, until a young and delicate woman is reduced to a shadow, and

the gland so injured that it cannot be used after any succeeding pregnancy.

The authors I have mentioned recommend warm applications at first, and the gentle use of mild liniments, the laying open of sinuses, (which Dr. Burns says truly, is very painful,) and simulating embrocations to remove any swelling that may remain.

I doubt not all my readers have had ample opportunities of trying and being disappointed by these remedies; and finding in some of the cases before alluded to, their inefficiency, either in arresting suppuration, or after that was established, in preventing the formation of sinuses, I resolved to change my treatment. The chief causes of sinuses—prolonged suppuration, swelling and consolidation, are undoubtedly the structure of the part in which the inflammation arises, and its loose pendant position obstructing the return of venous blood, and favouring infiltration of lymph, and the burrowing of matter.

My first principle in the treatment was to support the breast by a handkerchief placed beneath it and brought round the neck; then, if suppuration had not commenced, I covered the whole breast with strips of adhesive plaster, an inch wide and from nine to six inches long; the strapping commenced below, and extended from the arm pit, beneath the breast to the upper part of the sternum, successive strips were applied as high up as the nipple, leaving it uncovered, and then, in the same manner over the upper part of the gland, commencing at the top. The plaster was so applied as particularly to press on the indurated inflamed portion, and support the parts below it, but not to give pain by being too tight. It was removed when it became loose, and generally worn for a week or fortnight, until all swelling and hardness had disappeared. When suppuration had commenced, the breast was supported and a poultice applied till the abscess burst spontaneously or the matter was evacuated by the bistoury, and the strapping applied as above, a small hole being cut to allow the escape of the pus. The plaster was reapplied as often as the discharge rendered necessary, but not more often than I could avoid, as I preferred replacing a saturated or loose strip, to removing the whole oftener than every second day. This plan proved eminently successful, the formation of matter was arrested, old sinuses closed and healed, and no new ones formed; and under steady equable pressure, chronic indurations rapidly melted away. I should add, that the strapping used by me is composed of *emplastrum saponis* and *emplastrum plumbi*, spread on unglazed calico, and prepared by Messrs. Palmer and Palmer, druggists, of Birmingham, according to a form of Mr. Hodgson's.

It is, I think, much less irritating, more elastic, and less apt to cut at the edges than common adhesive plaster, and when good and fresh, at least as adhesive. I will, in conclusion, give the outlines of two cases, exemplifying the treatment.

Mrs. P., aged 27. This lady was confined for the third time early in May last. Breasts small; milk scanty and not sufficient to support her healthy infant.

At the end of a month she had in a great measure recovered her health, when, without any apparent cause, she was seized with headache, giddiness, thirst, and rigors, and the right breast became painful, hard, and marked with red lines beneath the axilla. The treatment was aperients, and fomentations to the breast; the next day three leeches were applied, with partial relief; on the day following the tenderness was still great with much hardness, the general symptoms much improved. The strapping was now applied, and remained on a week, when the breast was well. The supply of milk failed for three days, but afterwards returned. This lady had never before anything amiss with her breasts.

Mrs. B., aged 37. Has had four children. This woman was attended by a midwife at her confinement, which occurred early in May last. About a week afterwards I was sent for, and found her suffering from fever, of a morbid type, inclining to typhus; great constipation, succeeded by diarrhoea, &c. These symptoms yielded, and at the end of a week I left her convalescent, though much reduced, and with inflammation of the right breast, which the friends of the patient thought themselves competent to treat, as they had some years before cured an abscess of the other breast after it had lasted three months, and had left the gland useless, and indeed without the power of secreting milk, so that the woman nursed entirely by the right breast. About a fortnight afterwards I was again sent for. My patient was weaker than ever, and one or two abscesses were forming on the right side, and one on the left. I ordered nourishing diet, the breasts to be supported by handkerchiefs, and poulticed; they went on, however, badly; abscess after abscess formed and broke, or were lanced, on both sides; the breasts were riddled by sinuses, and much substance was lost in the right one from sloughing; the discharge was profuse, and the patient scarcely able to sit up in bed. On the right side there were, probably, eight or ten openings, from the size of a crown piece to a pin's head, most of them connected. On the left there was great induration, and more matter evidently forming, and four openings communicating with the sinuses. I applied the strapping on both sides, removing it for the first week every second day, afterwards every third. The induration, which had been accompanied by throbbing, shooting, and burning, disappeared from the left mamma, and the sinuses rapidly healed. On the right side the improvement was equally rapid, and in less than three weeks from the application of the plaster, the woman was pretty well, and the breasts perfectly and soundly healed, with very little contraction of the nipple on the right side.

Hospital Reports.

BRISTOL ROYAL INFIRMARY.

CASES

Reported under the Terms proposed by the Association.

BY NIL DESPERANDUM.

Dislocation of the Acromial End of the Clavicle.

THOMAS JENKINS, aged 21, admitted August 3rd, 1852, under the care of Mr. Green. An hour before admission he was standing in a narrow way, when a coal cart passed by, the wheel coming in contact with the outer part of the left shoulder, and pressing him against the wall. On examination the nature of the injury was at once evident, for the acromial end of the clavicle was plainly seen resting against the spine of the scapula, and under cover of the trapezius muscle. The part of the spine of the scapula where the clavicle was resting on, was nearly two inches from that part of the acromial process of the scapula to which it is normally articulated. Shortening of the distance between the neck and the shoulder was well-marked. In consequence of the support of the clavicle being gone, the shoulder came forward so as to give the impression that there was some displacement of the head of the humerus. There was some confusion of the soft parts at the outer and posterior aspect of the shoulder-joint. The clavicle was almost brought back to its normal position, by keeping the shoulders back, and raising the arm. A figure of 8 bandage was therefore applied, in the same manner as for fractured clavicle; and the arm was raised by a bandage under the elbow, and carried over the opposite shoulder. This treatment was continued up to August 21st, when he was discharged. There was but little deformity when he left the Infirmary.

This was an extreme case of displacement, for in most instances the clavicle is dislocated upwards on the acromion. There was the following circumstance to be noticed in this man:—On the other side, the clavicle and the acromion process were not on the same plane, so that on the application of great force, this condition of articulation would, I think, rather tend to dislocation, whereas, if the two bones had been on the same plane, the clavicle would have been most likely fractured.

Scrofulous Disease of the Knee—Amputation—Death.

JAMES LLOYD, aged 19, admitted October 25, 1851, under the care of Mr. Clark. He is of weak conformation, and the strumous diathesis is well marked. A week ago his right knee became very painful, so that he was obliged to give up his work, which was that of a carpenter; but three days previous to this he had severe rigors. At present there is some slight swelling below the patella, and he has severe pain on pressure. He has a discharge from the urethra, but it evidently

depends on phimosis, which no doubt is congenital. The first time he had any discharge from his urethra, was twelve months ago; but it subsided without doing anything for its removal. He has had a return of the discharge two or three times since. Hirudines xij. genu.

26th.—Pain was very severe last night; tenderness much the same, but is not quite so puffy below the patella; pulse 96; tongue moist and white.—R. Pulv. Ipecac. Co., gr. iij.; Ant. Pot. Tart., gr. 1-6th.; sextis horis sumend. Hirud. viij. Middle diet.

27th.—Pain a little relieved; swelling much increased, extending half way down the inner side of the leg; no effusion above the patella; pulse 120, full and compressible; tongue more furred; skin hot; bowels have been opened; great thirst.

28th.—Pain less; skin is red, and there is a feeling of fluctuation three inches below the patella; pulse 108; tongue dry; skin not so hot; not so much thirst. Discharge from the urethra continues. Has half a pint of milk with middle diet. Hirud. vj.

29th.—Pain and swelling are less about the knee; but have extended below the leg; ankle is puffy and œdematous. Does not sleep well. Pulse 120.

30th.—An incision was made in the inner side of the leg about the middle-third, and a little pus evacuated. Capiat pulvis quartis horis.

31st.—There is a free discharge of pus; ankle not so puffy; pain and swelling of knee less; pulse 112. Poultice to leg.

November 2nd.—Wound discharges freely, pus is not mature; the knee is reduced to normal size; pulse 108, weak; tongue cleaner, but is injected at the margins. Has considerable thirst and heat of skin. Discharge from urethra diminished. Omit pulveres.—R. Potass. Bicarb., Potass. Nitrat., utr. q. x.; Acid. Hydrocy. Dil., m. iij.; Aq., oz. iss. Fiat haust. quartis horis sum.

4th.—Discharge from leg is less, but on pressure, some cherry-like pus is brought away; pulse 92; tongue clean; not so much thirst or heat of skin. Ordered six ounces of mutton and half a pint of beer daily.

6th.—A large amount of pus is discharged on pressure, almost half a pint came away yesterday; pulse 120; tongue clean, but very red. Very little pain in knee or leg. To have one pint of beer daily.

7th.—Pus comes away more freely to day; is of a brownish colour as if from admixture with blood. Complaints of pain and tenderness in the bladder and urethra after passing water. Scarcely any discharge from urethra.—R. Potassæ Bicarb., scr. j.; Liq. Potas., m. x.; Mist. Tragacanth Co., oz. iss.; Tinct. Hyosc., m. xx.; sextis horis sumend.

8th.—The scalding is less to day. The tibia was found to be bare for about three inches, the probe passing for some distance under the integuments. General health the same. To have four ounces of port wine, one pint of beer, six ounces of mutton, and milk daily.

10th.—Pressure on the inner surface of the tibia brings away a large quantity of pus mixed with coagula; knee-joint is of normal size; scalding and pain in

making water have returned. Has had diarrhoea for the last two days.

12th.—The poultice was discontinued yesterday, and simple dressing applied; to-day the discharge has diminished to nearly one-half; feels stronger; diarrhoea has ceased.

18th.—Has remained much the same since the last report, with the exception of some soreness and pain in swallowing; cannot pass his water, only coming away in drops, with a good deal of pain.

19th.—The difficulty in passing water was much increased last evening, but after dilating the meatus urinarius with a probe, he passed water freely, and he has no difficulty to day; there is still considerable discharge from the leg, and there is some enlargement about the head of the tibia; pulse 120, weak; tongue clean and injected; appetite good.

20th.—On making pressure to-day on the outer side of the leg, between the tibia and fibula, a considerable quantity of pus came away, floating in which there was a good number of oil globules; is obliged to strain a good deal in passing water.—*Lotio Calcis Chlorid.* applied as a dressing.

December 1st.—There were more oil globules in the pus to-day.

5th.—The opening of the prepuce has contracted, requiring great efforts to pass his water. Opening dilated with the probe.

11th.—Complains of great pain in the knee, which is hot, but not swollen; had an eruption over him this morning, but which has now disappeared; passes water more freely.—*R. Pulv. Ipecac. Co., gr. v., sextis horis.* *Mist. Salina Antimonialis ter die sumend.* Poultice to knee.

13th.—Knee is much swollen, very painful, and fluctuates; there is oedema of the foot and ankle; has vomited several times to day; pulse 166; tongue furred and dry; cheeks flushed, in fact is in a state of hectic.—*R. Pulv. Trag. Co., dr. j.; Mist. Salin., oz. iss., quartis horis.*—*R. Tinct. Opii, m. xx.; Aq., oz. j., o. n. s.* To have fowl, and eight ounces of wine daily.

14th.—Is rather better; slept well, and has less pain in the knee, but the swelling is just the same; pulse 150; tongue moist and red; appetite improved slightly.

The symptoms of hectic rather increased than diminished, and there being no doubt that the joint was distended with pus, on the

26th Mr. Clark opened the joint on the inner side, and about a pint of well-formed, but very offensive pus escaped; tongue is ulcerated superficially on the dorsum.

27th.—Much easier; slept all night; there is an immense discharge from the knee; the leg is much everted, apparently from a displacement of the articulating surfaces of the thigh and leg; pulse 128, weak; tongue injected, and is more ulcerated; bowels relaxed at times; appetite not good, but he takes his wine and beer. Ordered the following application to the ulcers on the tongue:—*R. Argent. Nit., gr. iv.; Aq. Destill., oz. ss. M.*

January 1st, 1852.—Is very weak, the discharge from the knee being exceedingly profuse. A consultation was held as to the propriety of removing his leg, but it was considered that he was not strong enough to bear the operation.

Half-past 11, P.M.—A little better this evening; pulse 130.—*R. Tinct. Opii, m. xx.; Aq., oz. j., fiat haust. st.* Has taken two ounces of brandy.

2nd.—Slept last night, and seems a little better this morning.

3, P.M.—Has taken four ounces of brandy to day; pulse 160; blood comes away freely per urethram after passing water.

4, P.M.—He was placed under the influence of chloroform, and Mr. Clark removed the limb, about the middle-third of the thigh, by the circular method; on making the incision through the muscle, about half a pint of pus escaped. Very little blood lost.

9, P.M.—Going on well; pulse 130; has taken four ounces of brandy since the operation.—*R. Tinct. Opii, m. xx.; Aq., oz. j., st.*

3rd.—Slept tolerably well last night; pulse 125; took five ounces of brandy during the night.

5th.—Bandage removed; a little discharge from the stump; pulse 120. To take a little wine sometimes instead of the brandy.

6th.—Much the same; on removing the dressing, a dark, thin, offensive, unhealthy discharge escaped. The *Lotio Calcis Chlorid.*, and some turpentine, were applied, and then a bread poultice was wrapped around the stump. He took some fish for his dinner.

January 7th.—Did not sleep well last night. The poultice has occasioned some pain; pulse 120; the soft parts are sloughy. A dressing of turpentine and resin was applied, and another poultice.

8th.—Slept all night, and feels better this morning. He has a large bed-sore on the lower part of the back. The discharge from the stump is more healthy. A poultice of beer grounds and bread applied.

9th.—The soft parts sloughed to some extent, and the femur is denuded of its periosteum for nearly two inches. Takes his food pretty well. Pulse 130. To have eight ounces of wine and eight ounces of brandy daily. Yeast poultice to stump.

10th.—Is a little stronger, and his appetite is moderately good. The sloughing has ceased and there are a few granulations formed. To have a mutton chop for breakfast.

12th.—Enjoyed his chop yesterday. Bowels not opened since the operation.—*R. Pil. Rhei. Co., gr. v. Fiat pil. tertiis horis sum donec alv. respond.*

13th.—Slept well; pulse 124, weak. Bowels not yet moved, although he has taken four pills.

15th.—Is not so well to-day; has been sick, and is not able to take his food; pulse 128; bowels moved three times.

17th.—Was very sick all day yesterday, but is better to-day. He is very weak. Stump is dressed with simple ointment and plasters.

18th.—Is much worse to-day. Was constantly vomiting and retching during the night, but the pulse

did not call any one to his assistance, allowing the vomiting to go on unchecked. This morning he was ordered the Mist. Acid. Hydrocyanici, and to take soda water occasionally. Pulse is weak and intermittent and cannot be counted.

19th.—The sickness continued all day yesterday and through the night; and he died at six o'clock this morning.

No examination of the body could be obtained. On examining the amputated limb, the cartilages of the tibia were entirely destroyed; but those of the femur were not so much affected. The cartilage covering the head of the fibula was also ulcerated. There was not much pus present, on account of their having been such a free opening into the joint. A portion of the shaft of the tibia, for about four inches, was necrosed, and presented a smooth and shining appearance. Several nodules of new bone were present on the anterior and outer part of the tibia. The head of the tibia appeared carious—that is, the cancelli were much enlarged and filled with a reddish coloured fluid. The epiphyses of the femur, tibia, and fibula were not united to their respective shafts.

This is one of those unfortunate cases of necrosis of bone in the neighbourhood of a joint, in which the disease is propagated to the articulation and destroys it. There was extreme pain in the knee-joint for two days before any swelling came on; before this he was going on very favourably, and there appeared to be every chance of his getting well, although the suppuration (which was more profuse in this case than it is generally in necrosis) had weakened him considerably.

Aneurism by Anastomosis; Ligature of Right Carotid without relief; Partial cure by Galvanic Cautey.

ELIZA LANWORN, aged 25, a native of Wales, single. Occupation that of a servant. Admitted February 19th, 1852, under Mr. Prichard, for an aneurism by anastomosis, situated on the lower jaw. It commenced about six years and a half since, but had not given her any inconvenience till six weeks ago, when it became painful, and she had a sensation of beating in it, and she noticed that it was extending underneath the jaw, but otherwise it has remained much the same since she first observed it. She has enjoyed good health during all this period. The tumour consists of two lobes, as it were, the upper being about two inches in length, extending over the ramus of the jaw, commencing on the right side, opposite the angle of the mouth, and ending near the other angle; the under lobe is of rounder form, and the part of the tumour over the edge of the jaw connecting the two lobes is narrower than any other part. This connecting portion is situated a little to the right of the symphysis. The integuments are injected; she says that this resulted from the application of a blister. There is a distinct pulsation all over the tumour, but stronger on the left side in the under lobe. Pressure on the right common carotid stops pulsation in the greater part of the tumour, and

of course pressure on both carotids entirely. Pressure on the tumour by gutta percha was employed for a few days, but it had no effect on the disease.

March 4th.—The tumour having increased a little, Mr. Prichard ligatured the right common carotid. The incision was about two inches and a half long. A small artery required to be tied—a branch of the superior thyroid. The descendens noni was in its usual position, external to the sheath. There was some difficulty in securing the artery, from the space of operation being limited, by a venous branch crossing the sheath to join the external jugular vein. The artery was tied where the omo-hyoid crosses the sheath, the muscle being drawn a little upwards. After the ligature was tightened, the pulsation in the tumour was stopped in a great measure, and the right side of the face became blanched. She was under the influence of chloroform. The wound was brought together with two pins and twisted sutures.

Vespere.—Has been restless, and has vomited several times.—Ordered soda water.

5th.—Did not sleep; skin is hot; pulse 120; a good deal of thirst. The sickness continued, but was relieved by the Mist. Acid. Hydrocy. She has considerable cough.—R. Tinct. Opii, m. xx., horâ somni sumend.

6th.—Slept a little; the left side of the face is much hotter, and more flushed, than the other; the temporal and facial arteries pulsate strongly on the left side; cannot feel any pulsation in the right; a bruit can be heard over the tumour with the stethoscope; pulse 116; tongue rather dry; the pins were removed, the wound was united where the pins were inserted, but no union in the centre; the margins of the wound not inflamed; no suppuration.

7th.—Did not sleep last night, although she took twenty drops of tincture of opium; felt very much nauseated after taking the draught, and has vomited this morning; cough was troublesome in the night, but is less to-day; pulse 108; tongue moist; complains of pain in the head; there is not so much difference in the temperature of the two sides of the head and neck to-day; can feel pulsation in the tumour on the right side underneath the jaw.

8th.—Slept well without the draught; the pain in the head continues; no vomiting to day; pulse 108. Wound suppurating, but is united at the extremities; the margins are inflamed.

9th.—The cough and pain in the head much the same, the former being worse at night; pulse 100. The edges of the wound are not quite so much inflamed.

11th.—There is more suppuration, comes apparently from the situation of the ligature; headache and cough are less; pulse 100; bowels opened. There is a faint pulsation above the jaw on the right side.—To have one egg daily.

13th.—Wound still suppurating freely; the tumour is a little smaller; the cough and headache are but slight; pulse 96; tongue moist.

16th.—Has more pain in the head to-day, but otherwise feels very well; the tumour feels more flaccid, there is pulsation in every part, but it is not so strong. The wound has healed, with the exception of about half

an inch in the centre, at this spot (where the ligature is) there are fungous granulations.—Ordered fowl daily.

20th.—No apparent alteration in the tumour. There is but little suppuration from the wound; and the ligature is hanging farther out.

23rd.—Ligature came away while dressing the wound.

From this time, for the space of two months, nothing particular occurred to require a report. The pulsation gradually returned with its original force, and the tumour appeared to be extending somewhat, when Mr. Prichard determined to attack the disease locally. On May 27th, being placed under the influence of chloroform, a needle and thread was passed through the tumour in a transverse direction, to which was attached a piece of platinum wire; the two extremities of the platinum wire were connected with the copper wires of a galvanic battery, when in the course of a few seconds, the platinum wire was heated to whiteness. The connection of the battery was then broken, and the platinum wire passed through the tumour and heated to whiteness in two other places, at about equal distances from each other. I should say, that at one end, the platinum wire was soldered to the copper wire of the battery, but at the other the connection was effected by twisting the copper wire round the platinum. There was some little bleeding when the needle was passed, but it was immediately stopped when the platinum became heated.

28th.—Had considerable pain for some time after the operation. Vomited, but this no doubt arose from the chloroform. The tumour is larger, tender, and red, and pulsates stronger than it did before. The increase of pulsation is perceptible to the patient. No fever.

29th.—Swelling and redness increased. Pulsation not so strong.

June 1st.—Tumour is as much swollen as at last date, and is very painful. The redness is chiefly on the right side, underneath the jaw. There is a slight discharge from the openings and the sloughs are in process of separation.

5th.—The sloughs are detached, and the wounds are suppurating. Swelling and pulsation diminished.

From this date the tumour very gradually diminished, and the pulsation became weaker, especially in that part of the tumour above the ramus of the jaw, but the portion below the chin was not so much affected.

July 5th.—The operation was repeated. She was placed under the influence of chloroform. This time the needles were passed through the most vascular part of the tumour in a perpendicular direction, smart arterial hæmorrhage followed, but was speedily arrested when the connection with the battery was established. A compress of lint, and the bandage were applied.

6th.—Has passed an uncomfortable night, the tumour having throbbed and being at times extremely painful. She vomited an hour after the operation; complains of nausea, slight headache, and thirst; pulse 100; skin and tongue natural. Tumour is swollen and tender; but the action is chiefly confined to the spots where the needles were introduced. Pulsation strong over the symphysis menti. A cold water pad to be constantly applied.

8th.—Tumour more inflamed, being more swollen, tense, and shining, and very hot to the touch. A small slough is apparent at each aperture. No constitutional derangement. Continue the cold application.

10th.—Temperature and swelling of tumour increased since the last date. There is considerable tenderness. The sloughs are detached from two of the apertures, and the wounds are suppurating. Has a little headache, but no other ailment. Face is pallid.

14th.—Tumour is smaller, and not so tender. The apertures are larger, and are discharging laudable pus. Countenance less anæmic. Bowels and catamenia regular.

20th.—The apertures have healed by granulation, leaving the chin studded with small, depressed, firm cicatrices. The tumour feels firm, and is quite consolidated above the base of the jaw; underneath there is a circumscribed vascular patch, rather larger than a shilling, and giving an aneurismal sound; the integument is rather thin here. General health is good.

At her own urgent request she left the infirmary at the latter end of July, with strict injunctions to apply at once if there should be any tendency manifested of the tumour becoming larger.

I think that the treatment and progress of this case bear out very strongly the correctness of the opinion, that most cases of aneurism by anastomosis are to be only efficaciously treated by local means. Mr. Liston says:—"The cases are innumerable in which I have been obliged to employ the ligature in an effectual manner, combined or not with incision, where caustics, injections, puncturings, setons, and even imperfectly-applied ligatures had been previously resorted to, in vain." In this instance, certainly, the ligaturing of the carotid diminished the pulsation of the tumour, but after some time it returned with its almost original force, and the tumour was extending.

Of all local measures hitherto used in the treatment of these tumours, (at least when they are above a certain size,) the ligature has been the most effectual. The application of caustics, such as potass or nitric acid, would have been out of the question in a tumour of this size, as their use is attended with danger, from the profuse hæmorrhage that is likely to occur. Stimulating injections into the substance of these tumours have been sometimes employed, and with success; but some surgeons speak most decidedly against their employment in any cases, as their use has been followed by severe irritative fever, phlebitis, &c. It is only of late years that galvanism has been resorted to in the treatment of these cases. I think that the use of the platinum wires and the galvanic battery, is preferable to the ligature, and for these reasons:—1st, that the painful processes of strangulation of the tumour, and its subsequent ulceration are avoided; 2nd, that the skin is not destroyed, and thus the deformity of a large cicatrix is prevented.

It is to be regretted, that this woman was not entirely cured, as I think there was every probability she would have been with another slight operation.

WEST NORFOLK AND LYNN HOSPITAL.

CASES ADMITTED UNDER THE CARE OF CHARLES COTTON,
M.D., F.R.C.S., SENIOR SURGEON TO THE HOSPITAL.*

Stone in the Bladder—Lithotomy twenty-seven months after "cure"† by Lithotrity—Death, twenty-seventh day.

WILLIAM KEMP, asthmatic and infirm, aged 67 years, agricultural labourer. Admitted Jan. 24th, 1851. Conveyed to the hospital, a distance of ten miles, in a very hopeless condition, in order to seek relief for sufferings referred to the genital organs, which the friends of the patient describe as being beyond further endurance. On admission, the old man, pinched with cold, and fatigued by his journey, was found to be greatly emaciated, half childish, and extremely feeble; and on being stripped of his clothes and placed in a warm bed, several livid and abraded patches became apparent upon the knees, shins, and feet, said to be the effects of chilblains and scorching. He stated that he was a patient of the hospital about three years ago, when he had a stone crushed, and that on returning home he continued very well for several months, when his water began again occasionally to stop, and pass with difficulty; and that, although the symptoms gradually became worse, he would not consent to apply again at the hospital, because he was so old and ailing. Wishes now to be relieved of his misery. Says he makes water loaded with matter, frequently, and in small quantities; and with such dreadful pain, that he has long accustomed himself to the taking of as many as five and six pea-sized opium pills, during the day and night. Ordered full diet and gin, together with his usual allowance of opium.

January 28th.—Frequent and painful micturition; urine pale-coloured, alkaline, and depositing mucous and phosphatic matter in large quantity. Bladder explored with the sound, and calculus at once detected. Prefers porter or wine to gin. To have a mixture of muriated tincture of iron, henbane, and buchu.

February 1st.—Patient extremely weak, and unable to sit up any length of time; and in spite of the influence of his opiate, wandering about the ward at intervals during the night, drowsy and drivelling, disturbing the nurses and inmates with his wants and complainings.

2nd.—Consultation. Aspect of the case desperate; lithotomy under the influence of chloroform approved, as a *dernier resort*, and with a view to alleviate suffering. The irritation and pain consequent on the introduction of an instrument into the bladder rendered the sounding very imperfect; a suspicion, however, of the existence of more than one calculus was generally entertained.

5th.—Chloroform inhaled with marked success, and lithotomy by lateral section performed; the cutting gorget employed in the usual way, and the operation

completed without difficulty. Three calculi (tripple phosphates) removed, each having a small nucleus of oxalate of lime, and weighing—one, six drachms and ten grains; a second, two drachms one scruple; a third, two drachms. The patient was placed in bed, having an elastic tube introduced, when a slight oozing existing, the wound was immediately plugged, to prevent, as much as possible, any loss of blood.

Evening.—Tranquil and composed; no hæmorrhage. About three hours after the operation it was ascertained that the patient had unobserved withdrawn the elastic tube, leaving the plug within the wound.

6th.—Comfortable and easy; says he shall get well and be up to-morrow. Plug, by the side of which the urine dribbles away, removed.

7th.—Weak and wandering; pulse 96, small, and feeble; tongue clean, but dryish in the centre; urine passes freely through the wound. To have strong broth, egg-flip, and wine, and his pill of opium but three times a day.

8th.—Slightly improved in every way; has had pretty good sleep since two A.M., and wandered much less; tongue clean and moist; pulse 96, somewhat stronger; takes readily fluid nourishment, and has eaten an egg; sat up a short time in bed in the morning; was at first sleepy and cloudy, but afterwards became techy and irritable.

9th.—Has passed part of his urine by the natural channel. Aspect of the case generally encouraging.

10th.—No relapse in well doing.

11th.—Sudden drowsiness and exhaustion at noon. Complains of the wound smarting.—R. Spt. Eth. Sulph. Comp., dr. iij.; Spt. Ammon. Arom., dr. ij.; Syr. Zinziber., oz. ss.; Aq. Cinnam. ad., oz. viij. Ht. oz. j. quaque secunda vel. tertia horâ.

12th and 13th.—Improved. Eats again his food.

14th.—Another relapse; looks haggard and distressed; is in low spirits, and has refused his dinner; says he shall not get well, or live more than four or five days. Complains of considerable smarting from the urine passing at the seat of operation; wound, ash-coloured and sloughing. An elastic catheter introduced by the urethra and retained in the bladder, giving exit to about three ounces of urine. Wound dressed with tincture of benzoin.

15th.—Expresses himself better, and has eaten heartily. Withdrew catheter yesterday, about two hours after its introduction, and the water passes now "both ways" without inconvenience.

19th.—Appears in every way improved; appetite pretty good; perineal wound healing, although urine still escapes during micturition.

21st.—Listless and feeble; nates excoriated. Mixture of muriated tincture of iron given, and starch powder applied. Wound to be dressed with balsam of Peru.

24th.—Gradually becoming weaker. Appetite diminishing; tongue brownish and dry.

27th.—Hiccup and further weakness.

March 3rd.—Death from sheer exhaustion.

Post-mortem examination.—Beyond a thickening of

* Continued from page 475.

† See *Provincial Journal*, No. 17, 1852.

the coats of the bladder, and an hypertrophied condition of the kidneys, nothing unusual was observed about the urinary organs. A small sloughing opening, communicating with the urethra, remained at the seat of operation. The aorta and aortic valves were much degenerated from ossific deposition, and both pleuræ, together with the pericardium, were found generally, though not very firmly, adherent.

Operative procedure in this instance was resorted to, after much deliberation, with great unwillingness, solely as an act of duty and humanity towards a suffering fellow creature. The amount of relief from urinary distress, and the improvement in the state of the patient on more than one occasion, were so marked, as to give hopes of a successful issue; death, however, ultimately took place, after a prolonged struggle, when the *post-mortem* examination disclosed the existence, *previous* to the operation, of an advanced state of mortal disease and decay.

[To be continued.]

Proceedings of Societies.

LIVERPOOL MEDICO-ETHICAL SOCIETY.

AN ADDRESS

Delivered before the Liverpool Medico-Ethical Society, at their last General Meeting.

By THOS. BLACKBURN, Esq., VICE-PRESIDENT.

GENTLEMEN,—The Council of the Medico-Ethical Society have done me the honour to request that I would offer to your attention this evening a few general remarks on the nature, objects, and proceedings of the Institution; and in complying with their request I must throw myself upon your candour and indulgence, sensible that I am addressing gentlemen, many of whom are more fully acquainted with the subject than myself. Possibly there may be some present who have not thought much upon the subject, whose information concerning it is scanty or erroneous, and whose thoughts may be directed to a more thorough inquiry into its importance by the few plain remarks with which I propose to trouble you. I cannot pursue a course more likely to accomplish the purpose I have in view than by taking up in the order in which they are found in the general laws of the Institution, the various objects of the Society, and endeavouring to explain and illustrate them in succession. The first is stated to be:—

“To form a band of union amongst the members of the profession, and a medium through which their opinions can easily be ascertained and expressed.”

It has been said of poets and artists that they are *genus irritabile*, and I fear the same character applies in some degree to the members of our own noble and benevolent profession. How very prone are we to jealousies, estrangements, and misunderstandings among

ourselves, which not only injure the individuals who give way to them, but bring a discredit on the profession itself, and lower it in the estimation of the public. Now, no means of preventing such feelings from arising, or at any rate from displaying themselves, can be more effectual than mutual and confidential co-operation in the attainment of objects interesting alike to us all. A large proportion of the differences and contentions which arise, are the result of imperfect or incorrect information as to the conduct of the contending parties, and require only the opportunity of mutual explanation to be effectually removed. It becomes the members of a profession, having for its great purpose the relief of human suffering and the preservation of health and life, to cherish towards each other feelings of confidence and respect—to cultivate such a measure of friendly intercourse and fellowship in their pursuits and engagements, as may enable them to present to the public rather the appearance of an associated phalanx, labouring harmoniously in the service of humanity, than that of a body of rival tradesmen and money-grubbers, having no higher aim than to enrich themselves. It is evident that a society of this nature, having for its specific purposes the promotion of union and cordiality in the profession—the correction of those evils and irregularities which interfere with right feeling and the maintenance of those rules and regulations of propriety, courtesy, and decorum, which are so essential in the intercourse of men engaged in the same pursuits, and frequently in danger of coming in contact with each other—must have greater tendency to secure united action, than associations merely for the promotion of professional improvement. In this association the cultivation of right feelings towards each other, and the hinderance or removal of everything inconsistent with it, is one of the endorsed purposes of all our proceedings, and the very existence of a society, for such a design is calculated to fix the attention of the mind upon it, and thus to secure just apprehensions of its importance and value. Objects so truly desirable as these, however, can never be achieved—to such an extent and on such a scale as shall produce any decidedly favourable impression on the public mind, or render any really available service to the great body of the profession, unless a much larger proportion of the practitioners of the town and neighbourhood unite with the Society than have hitherto done so. If the proceedings of this meeting should have the effect of securing a large addition to our membership, and a more active co-operation amongst us for the promotion of our objects, we shall have much occasion to rejoice.

No man can have been resident for any length of time in Liverpool, and observant of what was passing around him, without perceiving the great inconvenience—indeed the positive injury—that has arisen again and again, from the want of some precise and recognised arrangement amongst us for calling together upon important public occasions the great body of the profession. Now, this Association, if generally supported, and if including in its membership a large proportion

of the resident practitioners (as it certainly ought to do) is just the very thing for meeting that exigency and supplying that want. It has passed into a proverb,—“that what is everybody’s business is nobody’s business,”—and so it often comes to pass that important occasions of expressing a general opinion on some subject specially interesting to us all, have either been lost, or so inadequately improved, as to do injury rather than good. On such occasions every man wishes that we should meet, but no one likes to assume the importance which appears to be involved in being the leader to call a meeting; and thus, between the spurious modesty of some, and the idle jealousy of others, nothing is effectually done. Now, an association, having for one of its specific objects to secure the assembling together of its own members on all important occasions, removes the difficulty. Its council and office-bearers are only discharging a duty devolved upon them by their constituency in summoning such a meeting, and bringing before them in a formal and distinct manner the business to be considered; and if the invitation to such a gathering should be extended beyond the membership of the Society, and the whole profession be urged to attend, no charge of presumption or undue forwardness can possibly be brought against them. At the present time, when schemes of medical reform are engaging so much attention;—when divers plans for education, and for effecting organizations to afford relief to indigent men in sickness, and to their families after their death;—and when the rules and arrangements in reference to our profession, adopted by the Poor-Law Commissioners and Boards of Guardians are so materially affecting the position of numbers, the absolute necessity of affording to the members of the profession the means of consultation, co-operation, and the expression of united opinion cannot be too strongly enforced. We do not do justice to ourselves as a portion of the great national family, entitled to be heard and attended to, and well able to give opinions which may influence nationally the decisions of the Legislature; and we fail to discharge an important duty to society, and especially to the poor, when we remain altogether silent on those matters in which Legislators are perhaps too willing to interfere, and of which our position and means of observation and knowledge eminently qualify us to judge. Union, therefore, for mutual support, mutual defence, and mutual assistance, is the main object of this Association. Have we not reason to acknowledge that there is amongst us generally a want of that *esprit de corps* which the dignified character of our profession, and the noble objects to which we are devoted ought to inspire? Let us learn to cherish a high estimation of the pursuits in which we are engaged, and whose great design it is to diminish the amount of misery that prevails around us—to extend the boundaries of knowledge on that most interesting question—by what means health may be preserved, or best restored. And let us learn to regard each other as fellow-labourers in the cause of humanity and benevolence—an *esprit de corps* founded on such principles and directed to such objects—while

it will tend to maintain peace and good will, and mutual respect amongst ourselves, will be in no danger of running into selfishness or excess.

The cultivation of this spirit of union and mutual respect, will be the most effectual way of advancing the general and social interests of the profession. Very much in proportion to the respect and estimation in which we hold each other, will be the respect and estimation which the public will accord to us. A generous spirit in recognising each other’s merits, and a ready and cheerful acknowledgment of each other’s attainments and talents; the cultivation of such a feeling towards each other as shall show that to commend and improve is our delight, and that censure is ever painful to us, and never indulged but from a sense of duty, cannot fail to advance the social interests of the profession at large. Nothing can permanently advance the interest, either of individuals or bodies of men, but genuine worth of character. Such an association as this has a direct tendency to promote moral worth and sterling integrity, by frowning upon and discouraging whatever is hollow, mean, tricky, and insecure; and by giving honour to the straightforward, the manly, and the genuine. The very fact of uniting together for such purposes we have in view in this Association, is calculated to promote the attainment of our aim. The man who has joined himself voluntarily to a society having in view the promotion of honourable and gentlemanly conduct in his profession, both towards his brethren and the public, must be made of strange stuff if the very circumstance of his having done so does not give an additional impulse to his own exertions in guarding against every temptation to go wrong. If we really wish that the noble profession in which we are engaged, and the history of which is illustrated by the names of some of the most celebrated philosophers and philanthropists of which the world can boast, should be justly estimated by the public, let us carefully avoid a jealous spirit towards each other, let detraction never be heard from our lips, let us dwell on the good and the excellent, and throw the mantle of a generous oblivion on the faults and failings of our brethren.

If the maxim be true that—“As a man thinketh in his heart so is he,” the cultivation of the generous spirit on which I have been dwelling, will render it a very easy matter to promote fair and honourable practice, and to decide on questions of professional usage and courtesy. Unfair and dishonourable practice and violations of professional usage and courtesy, are very rarely the result of mere ignorance or inadvertency. I do not say they are never to be traced to that course, but such instances are rare; and it is to such instances, I humbly apprehend, that the useful interference of the Society is limited. There may be occasions where errors are committed from sheer thoughtlessness or ignorance, and where the interposition of the Society to warn and instruct in the right way may be productive of much good. No man, however, will permanently act an honourable part who is not possessed of honourable feelings and upright principles. If there be not an internal perception of the right and the beautiful in

conduct, mere rules and regulations, however excellent in themselves, are utterly powerless.

Those matters included in the terms—professional usage and courtesy, and which may be denominated the polite *morale* of our intercourse with each other, have their foundation in the due regard to propriety, and the just attention to the feelings of others which in general society is designated by the term politeness. Where men, having confidence in each other, are associated in attendance, or brought in any way into connection, a very formal and punctilious attention to such matters is often by mutual consent dispensed with. As a general rule, however, the observance of them is safest and best. They are not mere conventional arrangements, of no intrinsic value or utility, but on the contrary, they arise out of the nature of things, and have acquired the character of usages and laws, because they have been found by long experience conducive to the advantage of all concerned—the patients and friends as well as the attendant practitioners.

As union is strength, and as by combined action strength is congregated as well as displayed, it becomes important that the means of correspondence and communication between professional men throughout the kingdom, in reference to medical interests, should be provided; and I know no method by which that object can be secured so effectually as by societies similar to this. If, in every large town, an association of this kind existed, and was in active operation, how comparatively easy would it be to elicit an expression of general opinion on any subject affecting the well-being of the profession. The moral influence of such a union could not fail to exert great power in the prevention of abuses, and the correction of evils. The modes of appointing medical men to public institutions and situations are worthy of much consideration, and it is not too much to say, capable of improvement. Without presuming to give any positive opinion on such questions, it may not be improper to remark, that they are deserving of the most careful and candid attention, both on the part of the public and the profession; that hitherto they have been very much left to chance or caprice, and have never yet received that systematic and careful examination in all their bearings on the interests of science and humanity to which they are eminently entitled. They constitute an important portion of the ethics of the profession, and demand and will reward the careful study and investigation of the most powerful minds among us. There does not appear to me any way so likely to bring the talent and intellect and research of the profession to bear effectually on such subjects, as the formation and combined action of societies of this nature.

There is a great diversity of opinion on the subject of medical polity—on the duty of the legislature in reference to our profession—but we shall all, I think, agree thus far, that if the Legislature is to interfere with us at all, it is our duty to give an anxious attention to its proceedings, and to take care that the interests of the profession and the public are not sacrificed by injudicious meddling. This is neither the place nor the time for

entering at length into the examination of any particular scheme or bill for what is called medical reform. I advert to the subject merely for the sake of remarking that the present state of affairs in this respect is such as to render it more than usually desirable that there should be in existence some regularly organized body, duly authorised, to watch the course of events, and to be on the alert to draw the attention of the medical man to any proposals or plans that may be brought forward. This is one recommendation of societies such as the one whose interests we are assembled to promote, and should induce every man who wishes well to his profession to swell its ranks.

I have thus, gentlemen, very hastily and cursorily run over the various objects, for the accomplishment of which, this association exists; and in doing so I have naturally been led to state the reasons which appear to me to entitle it to the support of the profession at large. A society which proposes to constitute a bond of union amongst the members of the profession, and a medium through which their opinions may be easily ascertained and expressed, which aims at advancing the general and social interest of the faculty, to promote fair and honourable practice, to decide on questions of usage and courtesy, to co-operate with similar institutions in other parts of the kingdom on all matters affecting medical interests, is surely deserving of support, and not only well calculated to effect purposes of great value and utility, but is in many points of view absolutely necessary if we intend to discharge aright the duties we owe to ourselves and the public. I recognise no distinction between the interest of the profession and the interest of the public. I believe them to be identical. The higher we raise our own standard of attainment and morals, the more effectually shall we promote the general weal.

Correspondence.

DR. MEREI ON TYPHUS FEVER.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In your last number I find Dr. Ogier Ward's letter concerning typhoid fever; and beg to reply that I will not fail, in its place, to pay due consideration to the interesting remarks it contains.

Typhus, I have found—or I might perhaps say, continuous fever, with the asthenic character—various in form and intensity, in various epidemics. I know not of any town where the abdominal form, of which the structural pathology has been so well defined by Rokitsansky, was more endemic and vehement than it was at Vienna many years ago. Still, even there, in some epidemics, a form was observed, which, for distinction, some have called *cerebral* typhus. As to children, my experience comes very near that of Drs. Rilliet and Barthez. Besides the well characterised typhus, I have seen cases of severe continued fever,

with or without diarrhoea, with a fatal end in a few days, and no typhoid ulcerations in the intestines, which, perhaps, might have been developed, however, if those tender patients had resisted the disease a longer time.

Concerning the hypersthenic and asthenic stages of continued fever, described in my last lectures, it is obvious, of course, that I do not consider them as *species* of fever; I only described in them real *objective* features, with some correspondent indications and management, as they occur sometimes, and destroy life, before a satisfactory, clear, specific character could be developed.

I beg, at the same time, to return my sincere thanks, for the Editorial remarks concerning my lectures. I could not have said to any one that I was willing to publish a separate work; for I sincerely confess that, as yet, I do not even feel the suitable disposition of mind to do so. I only think I shall, by-and-by, re-issue, in one volume, certain sections of the lectures you have the kindness to publish, with some corrections and supplements, which are very much required for their better comprehension; because the difficulties I had with the language itself caused very considerable faults in the first six or seven lectures, causing me in some places to write just the reverse of what I wished to say. In the series which are going on just now, I hope I have been able to avoid such great mistakes.

I am, Sir, your obedient Servant,
S. MERET.

[We were informed by a friend of Dr. Meret of his intentions, and requested to announce the fact. We regret that the announcement was premature.—ED. J.]

MR. PAUL ON OUR REMARKS UPON HIS CASE OF SCIRRHOUS PYLORUS.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—You have either mistaken the facts, or my language has misled you, in Higginson's case, reported by me in your last, and commented upon by yourself. From the phalanx of drugs detailed, my treatment was, as you may guess, *tout-a-fait*, gastric, regardless of liver. I suspected the pylorus all through; yet, in the face of authorities, both University and oppidan, so omnipotent, I confess I did lose somewhat of self-confidence. Farre's or Bright's was, I concluded, the disease, if any, of the liver. And we know that people live long enough with such a state of things. The head and front of his symptoms were, obstinate vomiting, pre-existent tympanitis, partial dropsy, and intense nocturnal pain.

With the infirmary staff, medical and surgical, I did not have in this, nor do I have in other cases, any communication, save in one recently, which I may possibly bring before your readers, as an instance of surgery's triumph. All my information was from the man himself, and after his death from his widow. "They all," said he, "told me my disease was the liver and the dropsy."

Mr. Briscoe does not prescribe save in a physician's

absence or in emergencies. To him, on the day of the *post-mortem* I wrote, as in courtesy I should, offering to show him the morbid specimen ere I immersed it in spirit. That was upon the 7th. The 12th is the date of my report; and on the 30th ultimo Mr. B. honoured me with a visit. He then told me "that a tumour was thought to be pressing upon the porta."

And this leads me, in conclusion, to a fact—incredible, no doubt, it will be to yourself and your readers—viz., that a law exists in the Radcliffe Infirmary, to the effect that the staff, medical and surgical, are not to divulge to their unattached *confrères* their treatment of intern patients. Nor, by the same law, are we permitted to witness operations. Will it be credited, Sir, that in this century—the nineteenth—of universal onward sciences, those of medicine and surgery, in this seat of learning, should be swayed by old Solon's law—"What is said or done, Sir, within these walls, passes not out through yonder door." What will our Associates, yourself among them, who flocked here from far and near, think of this, when they recal to mind all you and they saw and heard under the noble dome of another of Oxford's Radcliffe Memorials? In my *entrée* upon Oxford practice I observed a shyness in talking upon infirmary cases; coming as I did from London practice, it then excited my surprise, but now it only does my pity.

I am, Sir, your obedient Servant,
ANDREW PAUL.

September 20, 1852.

[It is a pity that Mr. Paul should place such reliance upon the reports of his non-medical patients as to make statements of the existence of disease founded upon them. Nothing is so likely to lead to error in judging of our fellow-practitioners; and had we known that there was no other foundation, we should not have inserted that portion of Mr. Paul's letter.—ED. J.]

Foreign Department.

GERMANY.

Amputation of the Cervix Uteri.

THE following has been abridged from *Fränkel's Handwörterbuch der Frauenkrankheiten*:—

The position of the patient for this operation is the same as that adopted in lithotomy. A bivalve speculum is to be introduced into the vagina, and then opened by pressure upon the handles. The advantage of this kind of speculum is, that it surrounds the tumour better, reaches completely the upper portion of the vagina, and removes the circular folds which must otherwise obscure the mouth of the uterus. The cervix uteri is then to be cleaned with a sponge, or bits of charpie, or by an injection. A pair of Museux's forceps, with long blades, is to be introduced closed into the speculum, opened at the cervix uteri, and fastened upon it as high up as possible before and behind; the branches are then to be pressed together, that the teeth may enter as deep as possible, so as to secure the deeper as well as the superficial structures. By moderate, slow, and continued traction, the vaginal portion of the uterus is to

be brought down with the hooks to the vulva. These tractions must be made gradually, and in the axis of the pelvis. In order, however, that the uterus may be the better brought down and secured, and that every part of the os uteri may form an equal projection, the operator may place another hook either before or behind, or diagonally through the diameter of the vaginal portion, according as the first hooks were placed. Traction is made by all the hooks together for five minutes, or in case of necessity, for a quarter of an hour, until the uterus is sufficiently drawn forth. This part of the operation is the most painful to the patient. The pain and difficulty proceed from the resistance of the ligaments. The forefinger is now passed up to the circumference of the insertion of the vagina to the uterus, which is recognised by a kind of ring, beyond which an empty space is felt. Standing at the left of the patient, the operator gives the hooks to an experienced assistant placed in front of the pelvis, and carefully cleans the neck of the uterus; he then takes a curved knife, cutting by its concave edge, provided with a covering of linen up to about an inch from its buttoned extremity, brings the edge of the instrument, guided by the forefinger of the left hand, under the os uteri, which is to be lifted a little upwards by the assistant, so as to expose more completely its posterior surface, after which he measures with this finger, the inner surface of which is to be applied to the patient, the height at which the cut is to be made. The knife rests upon the finger, and is directed by it as it is carried on, taking it for a point of support, whilst the assistant lets go the hook by degrees, so that the other points of the cervix are by turns to be drawn forth. The incision must be made slowly, and by short cuts, so that the labia may not be wounded, no unequal wound be made, and especially that the unequal prolongation of the degeneration does not give occasion to an irregular incision.

If the neck of the uterus be too large to be included within a speculum, so that this instrument cannot be used, the finger must be introduced into the vagina, and guided by it, a single hook passed into the cervix or some part of the tumour sufficiently firm to hold it.

Sometimes the cervix is not indeed very large, but soft, fungoid, and bleeds upon the slightest touch. Here the speculum is at least useless, for the os uteri would be shut out from the view by the bleeding, and no washing or injection would prevent it. In such a case it is better to apply a hook to the cervix uteri introduced upon the forefinger of the left hand. Yet it might be possible to use a bivalvular speculum, by opening it carefully, and before touching the tumour with it, so letting this fall in between the blades, and then applying the hooks.

If the vaginal portion of the uterus is too soft, and the ulceration has already made considerable progress, so that the hooks cannot seize any sound, or sufficiently sound part, they tear the tumour during traction, and bring away a portion of it with them. It is then often impossible with them to bring down the neck of the uterus out of the vagina; and the difficulty will be

increased if there be want of laxity of the ligaments, if the swelling be of unusual size, and there be narrowness of the parts. In the latter case Lisfranc does not hesitate to make room by an incision in the pudenda, in order to judge of the extent of the evil, and to bring the uterus through the external parts. Should it not be possible to draw down the neck of the uterus, the operation must be performed in its natural situation; for it would be attended with considerable difficulty and danger to introduce an instrument, invented by Guillon, through the os into the cavity of the uterus, which takes hold of the diseased parts from within, so as to make the internal surface of the organ the point of support in drawing the uterus down. It is clear that, with such an instrument, laceration and contusion must be occasioned, which it is the duty of the physician to avoid.

It is certainly a better plan to introduce a speculum, include the tumour within its blades, and then cut this off with an instrument. This may be done, either with Dupuytren's knife, or with one of two instruments invented by Hatin and Colombat, which cut the cervix uteri in a circle. Or better still, with a pair of curved scissors, especially recommended by Téallin; or his steel ring, which has an annular edge, and is fastened upon two branches, a cross bar, or a wide yielding circle, because parts can be removed by them which must be left by almost any other instrument. It is to be remarked that most of these instruments, which are all very complicated and difficult to handle, have the great objection that they cut off the diseased parts by a straight incision, whilst the disease itself has generally made a very uneven progress. The cut made with them almost always, in one part, goes beyond the parts necessary to be removed, and in another leaves a portion of the cancer behind. The simple blunt bistoury, for one who is tolerably accustomed to use it, is sufficient for performing the operation. It is to be carried either upon the finger or through the speculum to the cervix uteri. Whichever instrument is made use of, the rule always is to remove all parts that are affected by the disease. Lisfranc had the idea of performing the operation by two half-moon-shaped incisions, which met together, their great diameter being from before backwards. He then cut out a conical piece in the thickness of the organ, whose apex was above. By this plan he asserts that he met with very good success. The ill consequences which may arise from the operation are, hæmorrhage, metritis, and peritonitis, and various nervous affections. Hæmorrhage is the one most to be feared; yet this is seldom so violent as to require special treatment. Even when it does occur profusely we are not to take alarm immediately, for it empties the uterine vessels, and prevents inflammation. Should it meanwhile be really too profuse, and continue too long, it is to be stayed by injections of cold water and vinegar, or by a small hot iron. By using the speculum, the operator will be able to discover the place whence the blood proceeds, and to apply the cautery in the right situation. Should these means fail, the *tampon* may lastly be had recourse to. It is often sufficient to introduce the *tampon* into the vulva and a

little way into the vagina. After a few hours it can be withdrawn, and the bleeding will have ceased; but if it be not so, a fresh one is to be applied. But we should never be too much in a hurry to stop the hæmorrhage; for if stopped too quickly, inflammation may be the consequence, whereas this is prevented by an opposite course. When the *tampon* has been again removed, injections into the vagina are to be made use of, in order to remove the coagulated blood and serous and purulent matter collected there.

Inflammation of the uterus and peritoneum is, upon the whole, less to be expected when the bleeding has been free. Should it occur, however, it is to be treated in the same manner as any other traumatic inflammation. If the uterus be especially attacked, small, frequently-repeated bleedings from the arm are to be preferred to local bleedings. In inflammation of the peritoneum, on the contrary, local bleedings from the groin and abdomen are the most advantageous.

Shortly after the operation, Téallier sometimes met with very severe nervous affections, such as dyspnoea, convulsions, vomiting, &c. Still these accidents are always only sympathetic, and occasioned by the commotion of the nerves during the operation, which communicates itself to other nerves, and they quickly leave again when these have recovered. Composing and antispasmodic medicines are here of use.

By amputation of the cervix uteri, we substitute for an unhealthy and disorganising wound a simple one that may heal. The discharge of unhealthy matter stops at once, and a fluid suppuration is set up, such as takes place in all simple wounds. After superficial ulcerations, healing rapidly takes place; after the amputation, it does not go on so quickly, and the healing shows itself then by the formation of a cuticle, which covers the whole wound, and requires a longer time in order to become organised.

The cicatrix, subsequent to amputation of the cervix uteri, is at first very red, then it becomes white, and finally assumes the colour of the surrounding structure. This cicatrix may obliterate the orifice of the uterus, of which Lisfranc gives an example. This condition, however, does not prevent the flow of the menses, but only renders their escape difficult, producing symptoms of metritis. The menstrual fluid does not, therefore, collect in the uterus, but flows through the surface of the vagina. This obliteration may be prevented by the frequent introduction of the sound into the diminished orifice of the uterus.

In this way the healing of the incision is accomplished in the same manner as in other simple wounds. If pain and a tendency to inflammation be present, the healing will be promoted by emollient injections; if, on the contrary, it takes place too slowly, or the granulations are weak, a chlorine lotion will be useful; if the granulations arise too rapidly, they may be stopped by nitrate of silver. We may then use a dressing of charpie spread with emollient ointment, or soaked in emollient or narcotic decoction, and applied by means of a speculum to the wound.

Congestions of blood, to which the uterus is periodic-

ally subject when the critical period is not passed, exert an unfavourable influence upon the healing of the wound; and when they are considerable, and the organ has a tendency to inflame, we must bleed from the arm as soon as signs of inflammation show themselves, and the time for menstruation approaches. By this means the healing will be accelerated.

During the first period after the operation we may find the wound, to our comfort, putting on a healthy appearance and an inclination to heal. Yet, in the midst of the most favourable expectations, interruptions to the well-doing of the patient may occur, which one is inclined to attribute to this or that innocent circumstance—slight shiverings, followed by feverish symptoms; loss of appetite, or some difficulty of digestion; passing pain in the wound. The discharge becomes more serous and somewhat offensive. On examining the wound, one or more ill-looking spots are discovered, which contrast in colour with the red of the neighbouring structures. These points are soft, and one fancies they arise from the purulent matter; but they remain even after they have been washed. They are the commencement of a relapse. They make rapid progress, and soon destroy all hope of a cure. We must hasten to apply the cautery as deeply as possible, and the cauterization must be frequently repeated. Moreover, the part must be dressed with the chlorides, with opiate ointment, or with salves containing extractum cicute, belladonna, hyosciamus, with creasote, or Recamier's tincture. All causes which can be unfavourable to recovery are to be avoided; and if we succeed in putting a stop to the disease, and establishing a complete cure, the same watchfulness is to be continued to prevent another relapse. But unfortunately, in most cases, the greatest activity and circumspection can do nothing more. The disease begins its course again, affects the neighbouring surfaces, spreads to the adjoining organs, induces hectic fever, and the patient quickly dies.

Reviews.

Rheumatism, Gout, and Neuralgia, as affecting the Head and Ear, with Remarks on some forms of Headache, in connection with Deafness. By WM. HARVEY, Surgeon to the Royal Dispensary for Diseases of the Ear, etc. Renshaw, 1852, pp. 291.

THE columns of this journal have already contained an epitome of the views promulgated by Mr. Harvey on rheumatism and gout, affecting the head and ear; in the work now before us that epitome is enlarged and dwelt upon, the symptoms displayed at greater length, the treatment, both constitutional and local, as connected with all the varieties of the disease, and their sequelæ is clearly laid down, and the consequences of neglect in these hitherto almost

unknown forms of disease, are fairly and properly pointed out. The diagnosis is also demonstrated between the rheumatic, gouty, and neuralgic forms of otalgic disease; and upon all these points the author has evidently bestowed some pains. As drawing professional attention to some forms of disease not hitherto included in the catalogue of the "ills to which flesh is heir," the work now under our notice is deserving a careful perusal.

Provincial Medical & Surgical Journal.

WEDNESDAY, SEPTEMBER 29, 1852.

WE earnestly call the attention of the members of the Provincial Medical and Surgical Association to the annexed address of Dr. COWAN, and also to the letters of Dr. FORBES and Mr. DAYMAN, which, as expressing the various opinions of parties who have taken an interest in our periodical literature, are entitled to their attention and respect. It will be seen that Dr. FORBES (who was named on the committee, but who has since resigned) differs entirely from these gentlemen in his idea of the objects, as well as the proper composition, of the *Journal* of an Association like our own. His opinion is undoubtedly of great weight, and we are proud to observe, is in accordance with our own previously-expressed views, except on the subject of leading articles, upon which point we are almost inclined to agree with him; at all events, without some such arrangement as that which he proposes, they will never be generally acceptable; but we unhesitatingly subscribe to the assertion of Mr. DAYMAN, that if we are to have such leading articles as shall come up to the standard of general periodical literature, they cannot be the product of one brain, and must be paid for at a high price.

As the experiment is to be tried in London, we must impress upon our Associates, that unless they do their best to increase the funds by obtaining new members, as suggested by Dr. COWAN, the Society will be speedily swamped by a load of debt, which otherwise, as we have on former occasions foretold, will be the inevitable result. We have no doubt Dr. COWAN already finds the responsibility greater than he expected, and that, as is too often the case, the estimated

expenditure does not correspond with the actual outlay necessary. This is pretty clear, from the tone of his present address, which contrasts strangely with his sanguine anticipations, as expressed in his speech at Oxford. For the sake of the Association, however, let us strive to meet the expenditure, and if the produce should turn out to be proportionally good, we are quite sure that it will be hailed with satisfaction by every member at our next anniversary.

We have hitherto abstained, for various reasons, from offering our own plan, but as we shall not long have the opportunity, we may as well produce it, in conjunction with those of Dr. COWAN, Dr. FORBES, and Mr. DAYMAN. We think, then, that in order to conduct our journal efficiently, and at the same time at such a price as to come within the income of the Association, the following is the only one likely to produce a successful result. The greater part of this plan was last year laid by us before the *Journal*-Committee, but as it was then thought desirable to continue the "Transactions," it was not adopted by them:—

1st. We would have an Editor appointed who should have little or nothing to do with writing the articles composing the *Journal*, but should have full power to select the writers of them, and, where necessary, to pay for them. His duty should be, to obtain the foreign articles, the bibliographical notices, (which, we agree with Dr. FORBES, should be analyses rather than reviews,) &c., &c., and he must be answerable for them; the sums for these to be actually paid by the Treasurer, or some other responsible party.

2ndly. The Editor should have a regular establishment of compositors, &c., at the service of the Association only, by which means a large saving would be effected, and the contributors would have the privilege of obtaining extra copies of their articles at the mere price of the paper and labour required. This alone would be a boon sufficient to attract many who now have to pay a considerable sum for reprints.

By this plan we are quite certain that a weekly journal of thirty-two pages may be supplied to every member of the Association, stamped, for £800 per annum, over and above the receipts for advertisements; these are now about £200 a year, and would probably, with good management, and a weekly issue, amount to £400, but which we only calculate at £325. In addition,

therefore, to the above outlay of £800, there would be only the Editor and contributors to pay; and we know full well that foreign intelligence, superior to any which has ever yet been offered to the public, together with all the contributions necessary to form a first-rate periodical, may be afforded out of the surplus funds, without entailing any risk, or crippling the Association by debt. To this consummation we have long looked forward, but we have been disappointed in our hopes; and we have, therefore, as an anxious fellow-labourer in the Association, only to lay before our associates the results of that experience which we have gained in their service.

We do not positively know whether the arrangements of the *Journal* Committee are definitely concluded as to the printer and publisher, but we have reason to believe that the printers and publishers of the "*London Journal of Medicine*" are to be the favored individuals. It would be absurd, of course, for us to express any opinion as to the literary merits of that periodical; but certainly, in point of price, it was not a very good specimen of London economy; and we are afraid that its total failure, as a speculation, is no argument in favour of our adoption of its commercial managers.

To the Members of the Provincial Medical and Surgical Association.

GENTLEMEN,—It gives me very great satisfaction to be at length in a position to direct your attention to the following outline of publication which has been adopted by the *Journal* Committee; but I need scarcely remind you that, however abstractedly good it may appear, it can only be accomplished by extensive combination, and the exertion of your individual interests and energies in its behalf.

The most immediate and effective assistance in your power to render, is the obtaining fresh members and forwarding their names to our colleague and Editor, Dr. Cormack. Be encouraged by the reflection that all delicacy and difficulty in canvassing are now over, as you can appeal with confidence to the self-interest of every man, having more than a compensation to offer for the sacrifice you wish him to make.

Circulars will be forwarded to those gentlemen who will kindly undertake their distribution; and since heavy responsibility has been encountered, and no small labour expended by the Committee in the execution of the trust you have confided to them, you will, I doubt not, all feel honourably bound to adopt their cause as your own, and to do your utmost to raise our publication to that degree of usefulness, popularity, and influence, to which, if heartily and honestly supported, it cannot fail to attain.

The combining tendency and convenience of a cheap and really good and independent journal, *the property of the profession*, cannot be over estimated; and its becoming, as we trust and believe it will become, the chosen vehicle of expression to a very large proportion of British practitioners, attaches to it a prospective interest and importance which, at first sight, it might not seem to deserve. It may with perfect truth be asserted, that on the success of our journal depends the retrogression, the stagnancy, or the prosperity of our Association; and if we are ever permitted, in any adequate extent, to carry out those high and noble purposes which heralded our Institution, and still animate our founders, a consummation so desirable can only be efficiently realised by the instrumentality of a vigorously conducted periodical press.

The opportunity for successfully establishing such an agency is now before you, and with yourselves, and not with the Committee, rests the responsibility of failure.

I remain, Gentlemen,

Yours very faithfully,

CHARLES COWAN.

Reading, 20th September, 1852.

Address of the Journal Committee.

The Committee appointed at the Anniversary of the Provincial Medical and Surgical Association, held at Oxford, July 21st, 1852, with full powers to make the necessary arrangements for editing and publishing the *Journal* in London, avail themselves of the earliest opportunity of submitting to the members the following scheme of publication, and of earnestly requesting their active co-operation and support.

Of the great superiority of such a periodical, both as regards economy and independence, over every similar undertaking of a merely commercial character, there cannot be any reasonable doubt; and the opportunity now presented to the profession of raising the standard and improving the tone of our medical periodical literature, is one we should eagerly embrace.

The Committee are glad to be able to state that the new series will have the support of a greatly augmented staff of London and Provincial contributors, the proprietors of the *London Journal of Medicine* having consented to withdraw their periodical and to transfer their influence to the *Journal*; while in Dr. Cormack they have found an Editor whose long experience, acknowledged talents, and high literary qualifications, eminently fit him for the post.

It is intended that the new *Journal*, while it retains its original character as the organ of the Association, should secure, at the lowest possible expense, all those advantages which a weekly periodical is capable of affording; and that it should, by presenting a faithful digest of medical literature and science, as well as an attractive summary of professional news, render the purchase of any other periodical a matter of choice rather than of necessity.

The contents of each number will be usually classed under the following principal divisions:—

- 1.—Leading articles.
- 2.—Original communications.

- 3.—Bibliographical notices. (All new books to be noticed.)
- 4.—Periscopic review. (Careful retrospects and summaries, embracing everything that is new and important in all the British and Foreign Journals of Medicine.)
- 5.—Reports of societies. (Faithful, succinct, and early.)
- 6.—Association news.
- 7.—Topics of the day.
- 8.—Obituary.
- 9.—Appointments.
- 10.—The Editor's letter box.
- 11.—Advertisements.

The annual subscription to the Association is one guinea, which, in addition to the supply of the *Journal* postage free, includes the other privileges of membership. All legally qualified members of the medical profession (being regular practitioners) are eligible.

The necessary information may be obtained by applying to the General Secretary, James P. Sheppard, Esq., Worcester; to any of the Local Honorary Secretaries; or to Dr. Cormack, 37, Great Queen Street, Lincoln's Inn Fields.

In conclusion, the Committee would simply observe, that if the profession prove true to its best interests, the scheme which they have now the honour of proposing must result in effects of great and lasting importance.

CHARLES COWAN, M.D., CHAIRMAN.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—As it would appear that the question of the *Journal* is likely to be again discussed by the Association, I am desirous of submitting to the members, in a few words, the views I have long entertained respecting the plan and character which such a publication should possess.

1. In the first place, I think the acknowledged official journal of any literary or scientific society, should possess a special character, having direct, if not exclusive, relation to the nature and objects of the Society issuing it.

2. Secondly, I think it not only undignified but unjust, that a journal supported by the funds of a society, and presented to the members as part equivalent for their subscription, should enter into competition with journals originating in private enterprise and based on the commercial principle of claiming public support on independent grounds.

3. Thirdly, I think the principle most unsound that would seek to found the prosperity of such a Society as the Provincial Association, on the extraneous attractions of a journal of general interest, and not on the essential merits of the Society itself. This might be a very proper principle for a mere "*Provincial-Journal-Association*" to go upon, but must be ruinous if accepted as the basis of a society having dignified and noble aims of quite another kind.

4. I would, therefore, and for other reasons, venture to give it as my opinion, that wheresoever, or at whatsoever intervals, published, the "*Provincial Medical and Surgical Journal*," so long as it is acknowledged

as the official organ of the Association, should be strictly "*THE JOURNAL OF THE SOCIETY*," and make no attempt to imitate or rival any of the ordinary independent medical journals, whether of weekly, fortnightly, monthly, or quarterly publication.

5. I also venture to think, that when so restricted in its plan and principle, and while fulfilling its legitimate object as the organ of the Association, the *Journal* would prove far from useless or unattractive: it ought, assuredly, to be more acceptable than ever to all the members who are thoroughly conversant with the principles on which the Association was founded, and duly impressed with a sense of its real utility, dignity, and honour. I believe it to be quite impossible to combine the requisites of an independent journal, with the caution, reserve, and avoidance of offence to individuals, which ought to characterise the formal organ of a society. The history of the present journal sufficiently proves that these have not been combined in its pages.

6. The *Journal* arranged according to the plan suggested would consist of—

- a. Original communications from the members or others, on medical and other scientific subjects.
- b. Reports of hospitals and of the private practice of individuals.
- c. Special reports, prize essays, &c., authorized by the Association.
- d. Reports of the proceedings of the Association and its branches.
- e. Official documents issued by the Council or other acknowledged organs of the Association.
- f. Miscellaneous notices relating to the Association and its members.

The foregoing are, I think, all—or almost all—the kinds of communication that properly belong to the journal of such a Society as ours: but as I believe many members would desiderate something more, the following additional items might be allowed:—

g. Selections of important medical facts or new doctrines from the British and foreign journals.

h. Analyses (not criticisms) of valuable new works.

i. Medical news generally interesting—as notices of new publications, appointments, deaths, official documents of the medical corporations, societies, &c.

The most important change in the plan of the *Journal*, would be the abolition of LEADING ARTICLES, which seem to be altogether incompatible with the character of a Society's journal. I think every one must allow that the attempts hitherto made by the Editors of our journal to overcome this difficulty have proved entire failures. If it should be thought advisable to introduce such subjects as are commonly put into leading articles, let the articles bear the name or names of the writer or writers, whether Editor, Officer, Council, or Member.

In conclusion it may be incidentally noticed, that the abolition of leading articles and the exclusion or limitation of the amount of foreign selections, would greatly reduce the expense of Editorship, and set free a considerable sum for promoting other and more legitimate objects of the Association.

I am, Sir, your obedient Servant,

JOHN FORBES.

Old Burlington Street, London,
September 14, 1852.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—The present moment is one of peculiar interest to every member of our Association, and of considerable importance to a very large proportion of the medical profession in Great Britain. Two of our leading medical journals are about to change their Editorial management; the Editor of the *Medical Times and Gazette* has resigned a post which he has maintained with zeal and ability for many years, while the *Provincial Medical and Surgical Journal* is on the eve of a revolution which (whatever may be the opinion of individual members on the expediency of such reform) must inevitably alter the character of our public organ.

I shall abstain from any comment on the questionable language which has been employed in the recent attacks on the *Journal*. Enough has been said to convince us that the independent and gentlemanly tone of our present Editors is unsuited to the morbid appetites of some among us. There is, however, one circumstance connected with the subject, which appears to have escaped notice hitherto. We have been repeatedly told that our journal is not on a par with the other medical papers; but I take leave to observe that medical literature, in its periodical form, is generally of inferior quality to that which forms the staple of our principal journals, whether devoted to theology, law, or politics; and it may be well worth our while to inquire into the causes which have operated to produce this disparity.

The character and intrinsic worth of any journal are, of course, developed in its Editorial articles; and it is well ascertained that no single Editor, nor even two, can by themselves sustain, for any length of time, that vigour, elevation, and variety of interest, which an educated and scientific community has a right to expect in publications assuming to influence as well as to inform it. How, then, stands the fact with us at present? Simply thus:—The students of law, politics, and divinity, are ready to pay for their literary food; those of medicine either cannot or will not afford the means.

I trust, Sir, I may be permitted here to make a few remarks on the nature of "leaders" generally—remarks which I should not have ventured to obtrude had they not been grounded on careful observation and comparison of the very different degrees of interest with which the medical public receives the articles offered from time to time for its perusal.

We open our paper with expectations of finding there something to arrest attention, perhaps to arouse reflection; we encounter some detailed narrative of circumstances possessing only a local importance, or some vituperative assault on the character of a rival publication; and, indifferent or disgusted, we speedily throw it aside. But let us only contrast this unsatisfactory state of feeling with the relish we have in reading—the contentment in laying to heart, some well-digested essay, the subject of which is matter neither local, personal, or transitory; and we shall surely acknowledge as an axiom *that leading articles should be confined to the development, illustration, or application of PRINCIPLES*. These principles, I conceive to be divisible into *intellectual* and *moral*; in

either of which divisions a well-edited journal will render substantial service to our profession.

And, first, as to the improvement of our mental processes. It is notorious that in every branch of science (but in none more than our own,) observations and facts are accumulated with much more rapidity than we have them distributed into the classes to which they would properly belong. To what is this owing, but to a want of logical training, of accurate terminology, in the multitude of observers? Now, an ably-conducted journal would have for its object to remedy this grave defect. It would be continually holding up to view landmarks of thought and expression, such as might restrain the vagaries of fancy in theorists, and remove the perplexities of duller minds when bewildered by confusing detail.

With regard to the other, or moral division. Although it might seem, abstractedly, sufficient to appeal to the conscience of individuals, yet as the confessed tendencies of human practice are ever

"In pejus mere, ac retro sublapsa referri,"

it becomes the duty of the journalist occasionally to contrast old and well-tested principles of action with the novel and perhaps insidious infringements of them; and thus to maintain among us a pure and healthy state of feeling; exposing quackery under its variously-shifting forms, as what it really is when tried, either a positive untruth, or else the pernicious exaggeration of a truth; in both cases alike an offence against the Creator, whose providence it belies, no less than against his creature, with whose body it tampers.

Thus advocating whatever is sound and orderly in theory and practice, to the disparagement of all that is capricious, inconsiderate, and irregular, our journals will really be engaged in a task worthy of the noblest energies, the constant vindication,—namely, of those unchangeable, because Divine, appointments, which the great champion of order in the sixteenth century thus beautifully describes:—"Of law there can be no less acknowledged than that her seat is the bosom of God, her voice the harmony of the world: all things in heaven and earth do her homage, the very least as feeling her care, and the greatest as not exempted from her power; both angels and men, and creatures of what condition soever, though each in different sort and manner, yet all with uniform consent, admiring her as the mother of their peace and joy.*"

I am, Sir,

Your obedient Servant,

HENRY DAYMAN.

Milbrook, Southampton,
Sept. 22, 1852.

Medical Intelligence.

(From our own Correspondent.)

LONDON, SEPT. 27, 1852.

THE opinion of the medical public is greatly divided as to the propriety of the treatment to which the great DUKE OF WELLINGTON was subjected by his medical attendants in his last moments. A similar discussion

* Hooker, Eccl. Pol. B. 1, in fine.

arose respecting the measures adopted for the relief of two of the former colleagues in the Cabinet of the lately-departed son of England. In the case of one of these, (Mr. Huskisson, one of the earliest victims to railway accidents,) a lengthy war was maintained for some time in the medical journals, as to the propriety or impropriety of amputation immediate to the accident, without waiting for the passing of the shock, which in his case passed only with life; and in the other—a much more recent affair—that of a very great man also, the late Sir Robert Peel, there arose a considerable disquisition respecting the exhibition of chloroform, which it is said should have been used, so that a proper examination of the injuries received might be made—a step that could not be taken whilst the wounded Statesman retained consciousness. Many other suggestions were also made, all tending to show certain sins of omission or of commission, in the opinion of the critics, at least in the treatment of both these useful servants of their country.

England has had lately to deplore the loss of one infinitely greater than both these, and the event, though by no means unexpected, especially not so by the profession, has caused an universal gloom; nevertheless, already the tongues of those who could have treated the Duke's case so much better, have begun to wag, and strong and decided opinions have been expressed, to the effect that all was not done that should have been done, and something was done that should have been omitted.

The protracted fainting fits, which had occurred more than once, with other evidence, tend to show that the heart was the seat of morbid disorganization to a considerable extent—to fatty degeneration, in fact, arising probably from ossification of the coronary arteries. This is an opinion we gave some years since, to a friend inquiring for an explanation of a very serious attack of syncope, to which the Duke had very nearly fallen a victim; and it appears to have been entertained pretty generally by the profession, and to be the basis of the adverse criticisms we have alluded to. When that organ is the seat of a disease, especially of debility of its textures, indigestion is frequently one of its signs, is readily induced, and is also causative of much suffering, and not infrequently of the fatal termination. The symptoms on the Tuesday morning, therefore, after the full meal of venison the preceding evening, which Mr. Hulke regarded as so slight as only to require a more careful regimen of tea and dry toast, the critics consider should have been met more actively; and further, that when the Duke evidently became worse, instead of a depressing potion, such as an emetic, to void a stomach which, at the utmost, could have had little more than gas within it, stimulants, antacids and sedatives, such as brandy, ammonia, castor, valerian, and opium, with mustard poultices and other rubefacients, or even vesicants externally, were indicated. They consider that the exhibition of the emetic was peculiarly ill-timed when the epileptoid attack showed that the brain was suffering from a want of its due stimulant, and even the blood that did circulate in it was not of a normal or healthy character. It is most probable, however, that the attack was far too severe, and the system too prostrated, for any remedies, however strong and well indicated, to recal the fleeting powers of life. Writing without any knowledge of the results of a *post-*

mortem examination, if such has or is to be made, we anticipate from the previous history of the case, and from the symptoms attending the final departure, fatty degeneration of the heart, ossification of the coronary arteries, venous congestion of the brain, with ossification of some of the cerebral vessels, and probably some further cerebral disease.

The Duke was one of those who did not hold our profession in the highest esteem. He was even unwilling to have recourse to medical aid, and indeed, if it had been otherwise, it is probable he would now be still in the land of the living, for it is clear that he must have been suffering more or less throughout the night, yet it is not until the second visit from his valet, that he directed Mr. Hulke should be sent for. This is one of the infirmities that those who have enjoyed long-continued sound health are subject to, and yet one would have supposed that a strong-minded man, like the Duke, who, in the military hospitals during the Peninsular and other wars in which he was engaged, must have seen the vast utility of our sciences, would have disdained to foster. He carried the feeling, however, to a certain extent, into private life, notwithstanding his attachment to Dr. Hume. Few, if any, of the army surgeons present at the great battles of the 16th and 17th of June, were honoured with invitations to the Waterloo banquets, and their healths were always postponed to among the last. It has been a saying among the army surgeons, that the Duke was never wounded in any of his numerous encounters with the foe: had such been the case, he would have felt more for the army surgeon, and would have exerted himself to secure his comfort and that of the unhappy wounded. It is a singular fact that his great opponent, Bonaparte, was only once wounded, and then by a spent ball in the heel. It is said, nevertheless, that the Duke was in the habit of visiting his hospitals privately, and from personal inspection assuring himself that the wounded were taken proper care of.

One of our popular romance writers, describing a scene in the Peninsular wars, gives effect to the Duke's dislike for the army surgeons, by representing him as in active and familiar converse with one, whom he mistook for a field-officer—to whom the surgeon bore a considerable resemblance—until he discovered his mistake, when he somewhat harshly ordered him to the rear. We are not quite sure, but we fancy this anecdote is stated to be 'historical.'

A singular discovery has been made in France, by Dr. Frémy, physician to the central *bureau* of the hospitals, respecting the injurious influence of certain bracelets recently introduced to public notice under the name of *bracelets oderiferants composés de graines d'Amerique*. These American grains prove to be merely a composition covered with arsenite of copper, and perfumed with orris powder. In several instances they have caused a pustular eruption on the arm, together with sundry general symptoms indicative of danger. The reckless manufacturers and sellers of so dangerous a poison will doubtless meet with their desert in France, and then we may expect the bracelets to be introduced into this country, as was the case with the arsenicated candles some years since. Their manufacture not having been permitted in Paris, several dealers in the article sold them largely in London. What might have been the ultimate consequences to health,

it is hard to say, but we may fairly anticipate that breathing an atmosphere more or less charged with arsenic, cannot fail to break down and finally destroy the strongest constitution. Be that as it may, the mischief was not allowed to proceed, the late Mr. Everett, one of the most practical chemists we ever met with, discovered the secret. Attracted by the peculiar odour emitted by the burning snuff, after the candle had been extinguished, he made sundry investigations, ascertained the presence of arsenic in the stearine, and made known his discovery at several meetings of the medical societies, at the same time publishing a succedaneum for arsenic, equally efficient and in no way injurious. As it often happens, the publication of the wrong-doing was its death-blow, and we now hear nothing of arsenicated candles. The arsenic bracelets seem to take their place in poisoning the population. They may perhaps subserve the purpose of a Borgia: a husband anxious to get rid of a wife, may present her with the American-grained bracelets, and in like manner any female relative or enemy may be disposed of.

The connexion between the animal and vegetable kingdoms, at least as regards their products, has received an additional illustration of late. The leaves of the fir and pine have been so operated on as to produce a kind of wool, which for some time past has been used in a manufactory near Brislace, for the purpose of making coverlets, blankets, etc., the materials thus made, being warm, durable, and agreeable; they have a certain balsamic odour, inimical to insects. The leaves are found to consist of a fibrous material, held together by a resinous substance, which is dissolved by alkalies, the residue being used as the wool. The resinous matter, it is said, forms the basis of medicinal baths, useful in the treatment of many chronic diseases, and thus every part of the leaf comes into advantageous use. This discovery equals in value if it does not transcend that of the Chevalier Clausen.

The *vexata questio* respecting the right of the profession to a fee for answering the questions proposed by a life-assurance company, was again put to the test of law by the Messrs. Duplex, of Great Craven Street, who summoned the Economic Life Office in the Sheriff's Court, before Mr. Russell Gurney, for the sum of one guinea, for answering certain questions regarding a lady who was about to assure her life in that office. The plaintiff stated that he had answered the questions and sent back his reply, with a demand for £1. 1s., which not receiving, he commenced these proceedings. Mr. Gurney considered that the plaintiff need not have answered the questions without the fee, and decided against him. Medical men should remember this, and not answer any such queries until they have a written promise that the fee shall be paid. By acting in this manner lately, we have procured a fee from a repudiating office.

At the Colney Hatch Lunatic Asylum, Mr. Tyerman, of the Cornwall Asylum, has been elected to fill the place, left vacant by Dr. Hood's being chosen Medical Superintendent of Bethlehem Hospital. The office is that of resident medical officer for the male department; the emoluments are, £200 a year salary, with a residence, and £150 a year in lieu of board, with coals, candles, milk, and vegetables. There were no less than thirty-six candidates, some of whom were men of high repute in that particular branch of medicine. Mr. Tyerman, who was the successful candidate, had not even his name in the printed list; so that we may infer that very great interest was made in his behalf, even at the last moment. Mr. Marshall, lately house-surgeon to the Northampton Lunatic Asylum, has been appointed Medical Superintendent of the female department, in lieu of Mr. Davey, who is about to be the proprietor of a private lunatic asylum, near Bristol.

A sanatorium for convalescent phthisical patients, discharged from the hospital at Broughton, is about to be established at Bournemouth, in Hampshire. The subscriptions and donations have already flowed in pretty freely. The object is an excellent one.

The two great metropolitan parishes of St. Marylebone and St. Pancras are, as yet, free from the control of the Poor Law Board, and they seem determined to shew their freedom by most unhandsome and most ungenerous treatment of their medical officers, who have no appeal but the celebrated one from Philip drunk to Philip sober. The medical officers of St. Marylebone have long been the victims of this kind of conduct, and those who have dared to remonstrate are stigmatized as insolent in the extreme. It was formerly the practice that the assistant surgeon boarded in the house, but some time back this system was altered, it being found perhaps that they devoured too much provision. An order of the Board directed that these officers should have regular stipulated rations: so many loaves, so many pounds of meat, so many pints of porter, so much tea, and so much sugar *weekly*, and they were *rationed*, in fact, like soldiers or sailors,—we might even say like paupers; and so absurd, so insulting was the system—we hope it is not so now—that *Punch* caricatured it gloriously. The sister parish of St. Pancras seems anxious to emulate the Marylebone authorities. The affairs of this parish are conducted by a numerous vestry, and by a Board of Guardians, the latter elected by the former from among their own body. The medical staff consists of a surgeon to the workhouse, Mr. Robinson; a resident surgeon, Mr. Waldegrave, and district surgeons. Between the former workhouse surgeon and the master a war raged, each accusing the other of intruding upon his duties, and many an appeal passed to the vestry. When the master was dismissed lately, it might have been anticipated that all this would end, but not so; a medical committee, consisting of Mr. Hiles, Dr. (?) Hickman, and some others, have since contrived to keep the water hot, and there is scarcely a meeting of the vestry without a complaint from one or the other of the medical men. Some two or three months since a new election of district surgeons took place, and the new ones are not yet *warm in harness, their traces gall them still*. Some two or three meetings of the Board of Guardians were occupied in investigating a complaint made against the medical committee for interfering with the functions of the medical officers, in first discharging an alleged lunatic from the asylum wards of the house, to the general wards, and afterwards setting him free altogether, as it appeared, although he was declared to be dangerous. A wordy war ensued, the surgeons steadily defending their position, and shewing a just indignation at the interference, and the members of the committee, themselves medical men, plainly implying that the officers had mistaken the case, and asserting that the man was not mad, thus seeking to justify their own conduct, although one of them told the district surgeons that, as he had not visited the man the very day he was summoned, if any thing had happened he would have been in an awkward position. The affair ended by the Board warning the surgeons to be more cautious in future, neither of the surgeons so far compromising his dignity as to assent to or receive the caution. It is said the Alleged Lunatic's Friend Society are going to take up the case, and to prosecute the Doctors.

At a subsequent meeting the question was mooted as to the propriety of admitting as their medical officers gentlemen not provided with the licence of the Society of Apothecaries. It was contended that this was a document of but little value, and that it could be obtained by anyone by grinding—a process of which one of the Board seemed to have a rude idea, as may be supposed, when Mr. Harding gave, as one of the

duties of a grinder, the taking young men to places of amusement. Mr. Hillis asserted that a common shoe-black could make up drugs, and that there was no penalty attached to his so doing; but he did not venture to carry the parallel further, by asserting that he could prescribe and dispense for the sick, without incurring a penalty. The principles of free trade were invoked against such a monopoly as the Apothecaries' Society; but all the arguments failed, and the Board finally affirmed the principle that parish surgeons should obey the law, and be possessed of the double qualification.

The most recent quarrel or squabble was brought before the Vestry last week: it arose from a difference in opinion as regarded the diagnosis of a tumour between Mr. Hillis, on the part of the Medical Committee, and Mr. Rawlins, one of the district surgeons. The latter gentlemen felt so much annoyed at the matter as to send in his resignation; and certainly, if such things continue no one with the feelings of a gentleman can continue to hold office. Mr. Rawlins, it appears, certified that one of the paupers had a ventral hernia, and sent him to the Medical Committee for a truss. His opinion was supported by Mr. Hawker, Mr. Hancock, and Mr. Wakley, jun.; but the case was entertained by the Committee, and Mr. Hillis declared the tumour was a fatty one, referring the man to University College Hospital or the Veterinary College, it does not clearly appear which, for a further opinion. The matter having been thus brought before the Vestry, a Committee was appointed to investigate it, Dr. Gregory being the chairman; and they reported quite in Mr. Rawlins's favour, urged the withdrawal of his letter of resignation, and regretted that the Directors had not treated his letter with the attention it merited. A stormy debate followed; sharp and fierce language was used, and apologies demanded. Mr. Hillis defended his position, and was supported by Mr. Hickman; but the Vestry finally, with two dissentients, adopted the report of their Committee, thus tacitly censuring the Medical Committee for their uncalled for and gratuitous interference with the district surgeons. A similar bone of contention remains for the Vestry, with respect to a letter written by Mr. Robinson, with reference to the lunacy case already alluded to. His appeal was ultimately rejected by a small majority; and it was stated that Mr. Wildbore had paid the alleged lunatic £3, to avoid an action at law.

The medical officers of unions notoriously have enough to contend with, in the shape of hard work, paltry remuneration, and too many masters, but "in the lowest deep" there is "a lower deep," and it remained for the Medical Committee of St. Pancras, or rather for its medical members, to originate a continued system of annoyance against the unhappy officers, by the plan of supervising their diagnosis and treatment of disease, and counter-ordering the measures they direct. No man can or would put up with such treatment, and the members of the Committee will find it a difficult task to persuade their brethren that they have adopted and carried out a proper plan of proceeding.

The vestry of St. Pancras—*iterum iterumque Crispinus*—at a late meeting, resolved to adopt the new Interment Act passed last Session, and to appoint a Burial Board, thus commencing on their part the measures intended to purify the parish, and to enable the inhabitants to resist the attacks of the now rapidly-approaching epidemic. But alas! "a change has come o'er the spirit of their dream." To do this would cost monies; and what is human life as compared to the outlay of hard cash? The non-appointment of a Burial Board has been rejected by the Vestry in a spirit of sordid economy by twenty-one to seventeen. God help the poor; at the eve of a fearful mortality the medical officers are dispirited and annoyed by a shameful tyranny, and the only measure as yet proposed at all, of a sanitary character, is rejected by a majority of four.

A proposal is now on foot to establish a new society for the study and advancement of State medicine. The prospectus is now lying on our table. The promoters and Provisional Committee are Dr. Balfour, of the Royal Military Asylum; Dr. Bryson, R.N., of Somerset House; Dr. Marshall Hall, Dr. M'William, R.N., Mr. Martin, Dr. Ogle, Mr. Rumsey, Dr. Sharpey, Dr. G. Webster, and Dr. Wegg, with Mr. Pollock, one of the secretaries of the Pathological Society, as the Honorary Secretary. The principal object is to constitute a centre of such scientific and practical information as may be available for all purposes tending to promote public health, and consequently the prevention of disease, more especially those of an epidemic nature. It is, in fact, to be a society of practical hygiene. The Committee propose to investigate all circumstances, which tend to deteriorate the human race, and to lower its vigour and vitality; all that relates to the external causes of diseases, their propagation and their prevention, and all places for improving the physical, and through it the moral, condition of the people. The co-operation and assistance of all classes of society are solicited, for it is intended to restrict membership to the professors of the medical sciences, as all are and must be interested in the carrying out its objects. The annual subscription is to be one guinea. We wish it success.

It is said that a new kind of alcohol has been discovered by M. Wurtz, a professor at the Ecole de Médecine, at Paris, by repeated distillations of the oil obtained from potatoes. Its composition is represented to be $C_8H_{10}O_2$. He terms it *alcool entylque*. Another discovery has, we are told, furnished the profession with a powerful styptic. Eight ounces of gum benzoïn, with one pound of alum, boiled in ten pints of water in an earthenware vessel for eight hours, being frequently stirred the while, and water being added gradually, to make up the loss by boiling, will furnish, it is said, a supernatant liquid like champagne, possessing a slightly styptic taste and an agreeable odour. If but one drop then be added to a basin-full of blood, it will instantly coagulate the whole. This liquid is the discovery of Signor Pagliare, a Roman pharmacien.

COMPLIMENT TO THE PROFESSION.

The *London Gazette* of the 18th instant, announces the appointment by the Right Hon. the Earl of Warwick, the Lord-Lieutenant, of William Sands Cox, Esq., Professor of Surgery at the Queen's College, Birmingham, as a Deputy-Lieutenant in and for the county of Warwick. Mr. Sands Cox's Commission bears date September 3rd, 1852.

OBITUARY.

June 19th, at the advanced age of 78, Dr. Thomas Jefferies, formerly of Liverpool, and late of Castle House, Shrewsbury, one of the Vice-Presidents of the Provincial Medical and Surgical Association. His name is associated with the introduction of matico to the notice of the profession, and with the zealous cultivation of medical science.

September 20th, at Woolwich, John Dehane, M.D., of Wolverhampton.

TO CORRESPONDENTS.

We have received a communication from Mr. Cox, of Bath, but was too late for insertion in our present number.

Communications have been received from Mr. Newnham, Dr. Robertson, Dr. Jackson, Dr. Mercé, Dr. Silas Palmer, Chirurgus, and Mr. Cooke.

ALLSOPP'S PALE OR BITTER ALE.

IN consequence of the REPORTED ADULTERATION of BITTER BEER, Messrs. SAMUEL ALLSOPP and SONS have received numerous incidental TESTIMONIALS to the excellence, purity, and salutary effects of their ALES. They consider it due to the Medical Profession, who have so long recommended ALLSOPP'S PALE ALE in all cases where dietetic regimen is required, to give publicity to these Testimonials, as a means of disabusing the public mind of any possible prejudice on the subject.

By the following extracts among a number from the most eminent Medical Men, the Profession throughout the country will have the satisfaction of finding their just appreciation of the remedial advantages of ALLSOPP'S PALE ALE amply confirmed by the concurring testimony of the most able Physicians and Surgeons, as well as the most illustrious Chemists of the time :—

FROM BARON LIEBIG,

"The specimens of your PALE ALE sent to me have afforded me another opportunity of confirming its valuable qualities. I am myself an admirer of this beverage, and my own experience enables me to recommend it, in accordance with the opinion of the most eminent English Physicians, as a very agreeable and efficient tonic, and as a general beverage both for the invalid and the robust."—*"Giessen, May 6."*

FROM PROFESSOR GRAHAM, F.R.S., UNIVERSITY COLLEGE, LONDON; AND PROFESSOR HOFMANN, Ph.D., F.R.S., COLLEGE OF CHEMISTRY, LONDON.

"The sifting nature of the chemical examination which the Beers of Messrs. ALLSOPP's manufacture for many months past have been subjected to, fully establishes their incontestable purity. The process of brewing PALE ALE is one in which nothing but Water and the best Malt and Hops of the first quality are used: it is an operation of the greatest delicacy and care, which would be entirely ruined by any tampering with the materials employed."—*"London, April 26."*

FROM THE ANALYTICAL SANITARY COMMISSIONER OF THE "LANCET,"
MAY 15, 1852.

"From the pure and wholesome nature of the ingredients employed, the moderate proportion of alcohol present, and the very considerable quantity of aromatic anodyne bitter derived from hops contained in these Beers, they tend to preserve the tone and vigour of the stomach, and conduce to the restoration of the health of that organ when in a state of weakness or debility. They resemble, indeed, from their lightness, a *wine of malt*, rather than an ordinary fermented infusion; and it is very satisfactory to find, that a beverage of such general consumption is entirely free from every kind of impurity."

FROM SIR CHARLES M. CLARKE, BART., PHYSICIAN TO HER LATE MAJESTY THE QUEEN DOWAGER.

"I have frequently recommended BITTER ALE medicinally, and when my home-brewed Ale has been exhausted, I have been supplied with Ale 'from your brewery.'—*"Wigington Lodge, May 2."*

FROM THOMAS WATSON, M.D.

"In the genuineness and salubrity of PALE ALE and BITTER BEER, as manufactured at Burton, my confidence remains unshaken."—*"Henrietta Street, Cavendish Square, May 5."*

FROM GEORGE BUDD, M.D., SENIOR PHYSICIAN OF KING'S COLLEGE HOSPITAL.

"I did not want any testimony to satisfy me of the perfect purity of the PALE ALE manufactured by you. A close observation of its effects upon myself and upon many others to whom I have prescribed it long ago, convinced me, as much as the most searching chemical analysis could do, that it contains nothing more than malt and hops, and that it is a first-rate beverage."—*"Dover Street, May 1."*

FROM MARSHALL HALL, M.D., F.R.S.

"My confidence in the purity of your PALE ALE remains unshaken, and my opinion of its great value in a dietetic and remedial point of view, is entirely confirmed by long time and experience."—*"Grosvenor Street, April 30."*

FROM BENJAMIN TRAVERS, ESQ., F.R.S.

"I do not hesitate to affirm, that no deleterious substance is employed in ALLSOPP'S PALE ALE and BITTER BEER, and that my confidence in its wholesomeness as a beverage remains unshaken."—*"Green Street, April 30."*

ALLSOPP'S PALE OR BITTER ALE

May be obtained in Casks of all sizes from the BREWERY, BURTON-ON-TRENT; and from the undermentioned BRANCH ESTABLISHMENTS:—

LONDON, at 61, KING WILLIAM STREET,
CITY;
LIVERPOOL, at COOK STREET;
MANCHESTER, at DUCIE PLACE;

DUDLEY, at the ROYAL BREWERY;
GLASGOW, at 115, ST. VINCENT STREET;
DUBLIN, at ULSTER CHAMBERS, DAME STREET;

BIRMINGHAM, at MARKET HALL;

At either of which places a list of respectable parties who supply the Beer in Bottles, (and also in Casks at the same prices as from the Brewery,) may at any time be seen.

ALLSOPP'S PALE ALES AND BARON LIEBIG.

Although not in the habit of replying to anonymous advertisements, and although they cannot condescend to answer some of a very discreditable nature to the parties concerned, Messrs. ALLSOPP & SONS are compelled to take notice of an announcement bearing the name of Professor LIEBIG, to which an invidious publicity has been given. Messrs. ALLSOPP & SONS regret this necessity, as they have reason to suppose that advertisement has emanated from an unworthy jealousy on the part of those who should rather have shown gratitude for the labour and expense which Messrs. ALLSOPP & SONS have not spared to remove the otherwise ruinous prejudice impending over the Pale and Bitter Ales of this country, from the mistake of a French chemist.

Messrs. ALLSOPP & SONS would now call the attention of the public to the following points:—

That the original letter of BARON LIEBIG is addressed to Mr. HENRY ALLSOPP individually.

That he therein intimates that he had been applied to by Mr. HENRY ALLSOPP on the subject, and that his opinion had been requested, of course, for publication by that gentleman.

That he therein acknowledges the receipt of samples of ALLSOPP'S PALE ALES from the London bottlers, as well as other samples of the same, sent to him direct, by private friends. On these, he specifically founds the opinion reported by him to Mr. HENRY ALLSOPP in that letter—the general mention of the Burton brewers being incidental.

Thus, then, the letter of BARON LIEBIG, having been written for Messrs. ALLSOPP & SONS, and sent to Mr. HENRY ALLSOPP, on the subject of Messrs. ALLSOPP & SONS' ALES, they having, as they had, BARON LIEBIG'S authority to do so, were fully entitled to publish it.

Messrs. ALLSOPP & SONS consider it not unnecessary to add, that their intercourse with BARON LIEBIG is of some duration; they having frequently consulted the learned Professor on certain processes of brewing. And they are confident, therefore, that this last letter, anonymously issued, must either have been greatly mutilated previously to publication, or that it could only have been sent in reply to some wrong impression conveyed to that eminent man in respect to an alleged undue publicity given to his opinions.

Burton-upon-Trent, August 25, 1852.

PROFESSOR LIEBIG on ALLSOPP'S PALE ALE. FROM BARON LIEBIG TO MR. ALLSOPP.

"The specimens of your Pale Ale, sent to me, afforded me another opportunity of confirming its valuable properties. I am myself an admirer of this beverage, and my own experience enables me to recommend it, in accordance with the opinion of the most eminent English physicians, as a very agreeable and efficient tonic, and as a general beverage both for the invalid and the robust.

"JUSTUS LIEBIG.

"Giessen, May 6, 1852."

That the public might form a correct judgment of the intention of that eminent authority, Messrs. ALLSOPP and SONS have re-published BARON LIEBIG'S LETTER to Mr. ALLSOPP *in extenso*, in all the London Daily Journals, as well as in other Papers; copies of which letter, and of the very numerous and continually increasing professional testimonials in favour of their PALE and BITTER ALE, may be obtained on application at the Brewery, Burton-on-Trent; or at their Establishments in LONDON, LIVERPOOL, MANCHESTER, DUDLEY, GLASGOW, DUBLIN, BIRMINGHAM, and elsewhere.

VINEGAR.—In consequence of the publication in the LANCET of 28th ultimo, of a Series of Analyses of this Article, in which the Vinegar made by us is reported to contain *Sulphuric Acid*, we have addressed to the Editor of that periodical the following letter, and hope from his sense of justice, the adoption of the only honourable alternative—an acceptance of the challenge we have given, or an unhesitating withdrawal of the calumnious implication.

HILL, EVANS, and CO.

Worcester, September 9, 1852.

To the Editor of the Lancet.

Worcester, September 8, 1852.

Sir,—Our attention has been called to an article in the LANCET of the 28th of August last, on "Vinegar and its Adulterations." You therein describe the samples of vinegar, which you state to have been furnished by retail dealers as our vinegar, as containing a considerable quantity of sulphuric acid. You also state that the samples were not procured direct from the makers, because of the difficulty experienced in obtaining them by parties not engaged in the trade.

You will remember that, by a letter dated the 3rd day of January last, we offered for your inspection several bottles of our vinegar, and forwarded them to you through your publisher, Mr. Churchill, with a note from Sir Charles Hastings, M.D., of Worcester, vouching for our veracity.

We have also an authorized agent in London, Mr. Waters, of 15, Whitecross Street; we are, therefore, surprised at your statement that any difficulty existed in procuring samples, as far as our firm were concerned.

We reiterate positively our assertion in our letter of the 3rd of January, that no sulphuric acid is employed in our manufacture, and we therefore assert, that the results of the analysis published in your columns are mistaken, or that the vinegar subjected to your test was not the product of our manufactory.

We are willing to have samples of our vinegar subjected to the severest analysis by any two eminent chemists, the one to be named by yourself, and the other by ourselves,—the mode of procuring the samples to be decided by the gentlemen appointed; or we will submit our vinegar to any one of the undermentioned gentlemen:—Dr. Lyon Playfair, Dr. Graham, or Dr. Hoffman.

We propose that the expenses of the investigation should be paid by ourselves, provided it should be found that there is any free sulphuric acid in our vinegar, or any acid other than results from the fermentation of our grain wort; and that they should be paid by you, provided it be found that there be no such free sulphuric acid, or other acid than that resulting from the fermentation as before described.

In the latter case we should expect a notice of the result to be published in the LANCET, as our sole object is, to be vindicated from an unjust aspersion.

We write this letter without prejudice as to any ulterior proceedings which we may think fit to adopt, provided our offer be not complied with.

Your obedient servants,

HILL, EVANS, and Co.

FROM THE "LANCET" SEPTEMBER 18TH, P. 270, IN REPLY TO THE FOREGOING LETTER TO THE EDITOR.—"We have, therefore, very great satisfaction in adding to the four firms which do not use Sulphuric Acid in the manufacture of their Vinegars, and whose names have been already published, those of

MESSRS. HILL, EVANS, AND CO."

LECTURES ON THE DISEASES OF CHILDREN,

DELIVERED IN THE
Chatham Street School of Medicine, Manchester.

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Vienna, etc.

LECTURE XIV.—(Continued.)

Rheumatism: fever, and local affections. Different relations between local affections and fever of the kind. Febrile forms of rheumatism; the acutest, with general articular rheumatism—rare in infancy; a more moderate form more frequent, occurring even under the third year; the mildest form, which is the most frequently met with in young children. Local rheumatism considered in connexion with fever; the commencement always pain; its seat and further chances or passages. Rheumatic headache, along with fever. Rheumatism of the ear; pleurodynia difficult but important to distinguish from the beginning of pleurisy; frequent in young children, in connexion with fever. Lumbago. Rheumatism of the heart; pericarditis and endocarditis rare in the tender age. Dr. West's interesting table. Diagnostic inquiries and directions. Articular rheumatism, with fever, in various forms. Rheumatism of the stomach, intestines, and peritoneum.

GENTLEMEN,—In the last lecture I concluded my observations on two general features of fever, which I have called the hypersthenic and the asthenic, with some remarks on the general acute bilious character of fever. You will have noticed, what I have expressed in my eleventh lecture, that my purpose at present is not to establish *species* of fever, but to endeavour to give you some leading views in this difficult part of children's practice.

"Hypersthenic and asthenic," as you will have observed, denote for us two opposite general features of fever, considered *objectively*.

I concluded with observing that these features, or stages, pure and uncomplicated, are very rare in children. I said, if infants do not recover from high fever in very few days, they either die before the fever could go on into various special ways, or the fever takes one of the more or less protracted special forms. As you will see, what I have described as the "hypersthenic stage," can be connected with a variety of special forms of fever from their commencement. Now I will speak of these.

The distinguished Dr. Dietl, of Vienna, says in his work:—"There is a *febrile rheumatism*, but no *rheumatic fever*." I have not to enter into discussion upon this matter. My present task is a purely practical one. Fever appears in a great many forms and connections with various local affections; and I think

it to be useful to the young practitioner, in particular with regard to children, to draw his attention to, and make him familiar with, as many real features of fever as possible.

With regard to the rest. Is rheumatism merely a local affection? My answer is in the negative. The specific brick-coloured deposit of the urine itself is sufficient to prove a certain chemical alteration of the blood.

If we consider the disease in question clinically and without prejudice, we find there are cases where local rheumatism constitutes the primary and principal disease, from beginning to end; and the fever is of secondary importance. There are, however, other sets of cases, in which local rheumatism and fever nearly balance each other. And, finally, we meet with a kind, in which the general functional disorders constituting fever, are the first, the most salient, and important; whilst the local rheumatism—of muscles or nerves—is but an erratic complaint, *locally* unseizable and unmanageable; and the more so in the speechless child.

There is no disease in which it is more desirable than in this to recollect, as I recommended in other instances, all the different subjective symptoms (verbal complaints) we have got from adult patients. We see them sometimes, in the course of rheumatic fever, moan and suffer by uneasiness, sensations in the belly, head, or elsewhere, distressing to them and the attendants, which, in spite of their intelligence, they scarcely can explain. The same happens with the child; but the obscurity and anxiety are greater. I believe, therefore, it is desirable to investigate the matter practically, and elucidate, as far as we can, with children. My conviction is, that, just like as in scarlet fever or some other, there is, besides the peculiarity of the connected local affections, also a proper general character of the rheumatic fever; and I might even say the latter represents the very chameleon of fevers, just as local rheumatism represents that of local affections—both changeable every instant: a severe test for the skill of the practitioner.

Let us, then, consider rheumatism, first, in its—

Febrile forms.—The acutest is the most characteristic of all, generally known by the name of *acute articular rheumatism*. It is this:—We observe a *primary* paroxysm setting in suddenly, in most cases by rigor, with subsequent heat; and at the same time with the rigor, or during the heat, or shortly before the rigor, pain appears in both ankles or knees, less often in other joints; but more or less rapidly it extends thence over the rest; when, besides the high and almost burning heat, and the most acute pain, the affected joints commence to swell with the increase of the fever. But then, in the course of a day or two, profuse sweat will appear; and this forms a decisive moment—good or bad. If the local affections under that sweat do not lessen, you have commonly a severe and pertinacious disease to contend with, which, by-and-by becoming remittent, and presenting a continuous alternation between exacerbations, dry heat, and alleviating perspirations, or unalleviating profuse sweat, may last for weeks or

afterwards it became clear that there was no inflammation, but erratic rheumatism.

Within twenty-four hours this will, in the great majority, and particularly in young children, become clear, because in that time either remission, or even a second exacerbation after remission, will have taken place. Only in rare and vehement cases this sometimes happens the second day, and in this case, in fact, we cannot make so clear the matter, as to be allowed to delay longer than twelve or twenty-four hours, subtracting blood as a measure of prudence.

In the great majority of cases rheumatic fever shows remission and sweat within twenty-four hours; and then, if in spite of this the signs of acute pain in some part of the head persist, I consider this as rheumatic headache; and if the signs of headache remit along with the fever, and reappear more intensely with a new exacerbation, there is almost every certainty of its neither being nor becoming meningitis, be that headache rheumatic or otherwise. Profuse and not alleviating sweat, makes the rheumatic nature of the headache still clearer. You must not forget also in this instance, what I said already in another lecture, that in febrile headache the child lies rather quietly moaning; under an acute local pain of the head, like that of rheumatism, there is more moving about with the head, or with one of the hands towards the head, more like in the beginning of meningitis.

Rheumatism of the eye, along with fever of the kind, is not unfrequent in children. In its fixed and inflammatory form, in the serous or fibrous tissues of the eye, it is too well known and easily perceptible on the child, to require a particular mention here. It attacks commonly only one eye, or at least one prominently severe.

Rheumatism of the eye, generally remittent and connected with a mild remittent fever, or no fever at all, will be discoverable in little children by the different sensibility and appearance of the affected eye. The eyelids are less open, and move less freely than those of the other eye.

Next I must mention the *rheumatism of the ear*. This is also very difficult to diagnosticate, when it comes along with the fever, in the first twenty-four hours; but the second day, either the fever will have remitted, and the signs of earache become more prominent; or if otitis has to develop, already some swelling and tenderness of the respective parts will be discoverable by the skillful practitioner. Other objective signs of pain in the ear in little children, consist in some movement of one of the hands towards one of the ears, and that the child if set upright in the arms, drops the head towards the affected side. In the great majority of the cases of acute otitis I saw connected with it moderate or slight, and remittent fever; and otalgia, which very generally appears to be of rheumatic origin, and in which the pain is by far the most violent, generally not connected with fever at all. On these subjects therefore, I will speak more properly under the head of chronic rheumatism.

Pleurodynia is frequently connected with rheumatic fevers of children, mild as well as severe. It can have

its seat, there is no doubt, in the pulmonary pleura; but commonly it is the costal pleura and adjacent muscles, together, or separately each of these parts.

I cannot say in which side I have more frequently observed rheumatic pleurodynia; but I believe constantly on one only. It is a severe pain, vehemently increasing by the respiratory movement of the chest in deep inspiration. In fact, the child's breathing in this case will appear to be superficial and cut short; and both fever and acute pain will concert in giving the child an alarming aspect.

In general it will lie quietly on one side, half dozing, interruptedly moaning, with closed eyes. As soon as the mother tries to take it up or change its position, it commences to cry, but at once we see it is checked in doing so by pain. Under this circumstance, commonly some dry short cough comes forth; and in some cases this happens repeatedly for some time, even if the child has not been moved at all.

Now this I have noticed frequently; and it has not seldom been mistaken for pleurisy. And there is no doubt *pleurodynia, connected with fever, looks to the eye decidedly and in everything like pleurisy* in its first stage, before exudation has taken place. Nay, what is more, we auscultate, and find negative results equal in both cases. In instances, where the pain is in the pulmonary serous membrane, or in the costal pleura, but very intense, this side of the chest moves less than the other, and the respiratory sound is lessened, just as in the commencement of pleurisy. But let me remark that this uncertainty can last for you only between twelve and twenty-four hours; *because* rheumatic pain of those parts, if connected with fever, may continue in the same way for some time; but pleurisy, if it has to come, will show itself in children, according to my experience, within the first twenty-four hours of fever, and most frequently within the first twelve, by some friction-sound at one side of the chest; and afterwards by the more significative dullness on percussion.

Thus stands the diagnosis in cases where the pleura alone, without the intercostal muscles, is the seat of pain; in most instances, however, the latter will be affected too; and then, by careful touching and pressing with our fingers upon the intercostal spaces, we shall see clear at once; because it will appear that the pain is very superficial, which is not the case with pleurisy; for in this case the child will bear our touch better.

As to posture, according to my experience the little patients lie, in pleurisy as well as in pleurodynia, if the pain is very severe, generally on the healthy side, or on the back.

But let us suppose, now, the child lies from the preceding day in high fever, heavily moaning, in depressed immobility; his respiration is short and frequent (which, of course, it is in high fever of any kind); there is not the least cough; and the mother did not notice, nor tell you, that in moving the child lively expressions of pain come forth; and the like. Let this all be so; still there are means of ascertaining the presence and seat of pain, if even it were limited to only a small spot of the chest, and even allow some passive move-

ment, without considerable increase of the pain. This means I have already mentioned; it is to push gently, but with gradually increasing pressure, the abdominal viscera towards the diaphragm, whereby forcible inspirations being produced, it will soon become clear that this act is prevented by pain. And as auscultation and percussion will give you negative results, it will be nearly certain by that double circumstance, that there is pain outside the lung, or even outside the chest, in the muscles. This being ascertained, exploration by touch may still bring you nearer to exactness.

But, as I mentioned before, though pleurodynia, with high fever, in the first twelve hours, or longer, may completely imitate beginning pleurisy, consequently, in a strong child, even require leeching, as means of prudence; yet towards the end of the first, or on the second day, the fever having become more or less remittent, and the above chest-symptoms persisting still, without further physical change in the respiratory sounds, then you may be sure that you have rheumatic pleurodyny before you, and no danger of exudation.

I have dwelt so long upon that apparently little subject, because I have seen a good deal of anxiety, confusion, or mistake about it—because it is a frequent form of rheumatism with children, and nowhere you find directions concerning it in the speechless patient. If we wish to keep up the credit and honour of our remedies in the present age, we must pay increasing attention to every subject of practical concern. It is not indifferent, if in cases just alluded to, a child is leeches, or not leeches. A few days ago I had to attend a child, three years old, of my distinguished colleague, Mr. N., a child (with the rare peculiarity, that till the present day there was no possibility of getting into her mouth anything besides milk and water) of a very delicate constitution. She had a strong fever, with pleurodyny. Leeches in this case were not an indifferent question.

Lumbago, or let us say rheumatism of some muscular part near the loins, is also a frequent comparison of rheumatic fever in children. I happened, many and many times, to discover it in children' one or two years old. I found it seldom connected with high fever, but almost always with a moderate or slight degree. Lumbago itself is variable in intensity. If both lumbago and fever are strong, then the child lies on his back, with superficial breathing, steadily in the same posture, with the eyes shut, and heavily moaning, entirely resembling acute instances of muscular pleurodynia, with the only difference that the immobility is still greater in lumbago; and the slightest change in position causes vehement crying, which, of course, soon becomes checked by pain.

In severe degrees of this affection its presence can scarcely escape the attention of a careful mother or physician, and this being clear, a minute examination by touch and pressure by our finger, auscultation, and some purposely but gently-performed movements, will make the diagnosis of the locality clear.

Slight degrees of lumbago, however, are easily overlooked in a young child, or, as I have seen it, con-

founded with pleurodynia, and mustard poultices placed under the armpit, instead of the lumbar region. Be very exact in your examining and diagnostical proceedings with children, and you will not be frequently mistaken in that way.

Rheumatism of the heart. Pericarditis, and endocarditis, I am sure, are exceedingly rare in infants, but as they are far more dangerous to life than in adults, it is our duty to watch the child carefully, and auscultate twice or more every day, as soon and as long as signs of rheumatic fever is perceptible; I should say, perhaps, as long as signs of the rheumatic diathesis are present in the child.

After all that I have seen, I must believe, that amongst acute affections of the heart in children, the great majority are owing to rheumatism. Of the chronic form I shall not speak in this place.

Let me request you to peruse carefully the table of my distinguished colleague Dr. West, of London, which is annexed to his "Lecture on Diseases of the Heart,"—a short but excellent treatise on that subject, containing a comparative survey of thirty-three cases of diseases of the heart in children, which in many respects it will be useful to you to have carefully looked through. Nine acute cases are of the rheumatic origin, and a great many others of the chronic kind, of which the earliest commencement is not known. Many of them have arisen from the same source.

I am exceedingly sorry that I am, as yet, at a loss for figures concerning that disease taken from my practice at Pesth; but you will be surprised, knowing the excessive frequency of rheumatism there, when I say I am sure that all diseases of the heart which we have witnessed and recorded in the Children's Hospital, (upon about 16,500 various diseases treated there till the summer of 1849,) there will scarcely be more than half a dozen children under the fifth year of age; at the same time I must express my conviction, according to which, amongst all cardiac and pericardiac affections which I have seen in the hospital, as well as in an extensive consulting practice, from infancy up to puberty, of which the total number scarcely may exceed sixty or seventy—that, amongst these cases, almost all, which were not *secondary* hypertrophies or dilatations of the right ventricle, (in consequence of chronic bronchopneumonia in older children,) and of which we could get some good data, or examination near their commencement, almost all were considered by us as of rheumatic origin.

Some authors state the affection in question to be far more frequent in infancy; I did not find it so. And it appeared to me, that most of the cases of valvular, or in general endocardial affections, which I have seen in adult patients, originated rather from what some have called *gouty* rheumatism, or simply from gout, than from simple rheumatism. Both the former are not proper to infancy.

In this place I have not to speak in detail on affections of the heart, I have only to point out to you the rheumatic origin of most of them in children, and give you some hints how to perceive their first beginning in

a speechless child. First, you may look at it as possibly a case of acute articular rheumatism; but then, any fever with the rheumatic character, (of which I will speak by-and-by,) in particular as long as the urine maintains the specific deposit, can produce rheumatism of the heart. The most frequent seat of it in children, I believe, is the pericardium, and less frequent the endocardium. As long as rheumatism of these parts exists only in the form of pain, it will be scarcely possible for you to distinguish it in a little child from pleurodynia, when the pleura aches just near the heart. I have met with cases where strong palpitation has been present during fever of the rheumatic character, along with heavy painful moaning, short and frequent inspirations,—where, in spite of the absence of either pericardial friction or endocardial murmurs, I referred the pain to the heart; it is, however, impossible at that stage of rheumatism of this organ, to exactly distinguish if it be in the peri- or the endocardium. I have had cases of that kind, in which pain and palpitation have ceased quickly or slowly, without a sign of material change.

If rheumatism commences to go on the course of inflammation in the heart, then the slightest friction-sound, or the slightest bellows-murmur, (let us say any kind and degree of endocardial murmur,) must act upon your mind as an imperious reason to check it, if possible, at that early stage, by energetic treatment.

The question, however, is,—*Is every pain of the heart or pericardium during rheumatic fever liable to produce structural changes or exudations?* According to my belief, I must say not. At Pesth, in adult patients, (nay, in myself, and I was for some years very frequently affected with rheumatic fever and articular rheumatism,) very frequently I had cases in which a decided muscular rheumatism, either of the shoulder, loins—or, even rheumatism of the knee, suddenly leaped on the heart, causing so severe a pain in this organ, with or without palpitation, that some patients described it as atrocious; then it passed, after hours or days, entirely, or returned again, and no mischief has been produced. Where these attacks of pain in the muscular tissue, in the serous lining, or in some nerve? I do not know, but I strongly believe that rheumatism of this noble organ is not rare in adults; and in some cases, as far as I could ascertain, I thought I had before me the same form many times in children.

As to *articular rheumatism*—be it simply pain or inflammatory disease—I mentioned already that it is the most easily recognizable rheumatic local affection, even during the symptoms of fever, so troublesome and alarming in a child. I will speak more particularly of it in a future lecture, under the head of chronic rheumatism. Here I only wish to mention, that in general the joints, but amongst these the knees are the most frequently injured or destroyed by rheumatism in children, I at least saw them affected and disorganized much more frequently than the ankles or elbows at that age. I saw the acute inflammatory, as well as the destructive chronic form, with their bad results. For my present purpose, which concerns these articular

affections only as far and as long as they are *febrile*, it will be sufficient to point out their early origin, soon after, along with, or a little before a vehement paroxysm; and in order to be successful in checking them, I will recommend you, once more, not to neglect, in any primary paroxysm, to move and touch carefully all the joints of the child; thus it is scarcely possible to overlook that form.

I mentioned at the head of this lecture, in children under three years I seldom saw the general acute articular rheumatism, as we meet with it in adults; commonly in young children only one or two joints are affected. Simple rheumatism, with all its changeable attributes, is more frequent in the arm-joint, next in the knee.

The *rheumatism of the neck*, so well known as productive of the torticollis, was in my practice not so rare an occurrence in rheumatic fever of young children; it is easily distinguishable by the repeatedly-mentioned means of investigating a child. It is not dangerous; no swelling nor suppuration will ensue, but not seldom permanent contractions, *i.e.*, torticollis.

Let it be observed, the disagreeable issue of rheumatism of muscles or tendons, is contraction; that of serous and fibrous membranes, exudations of various kinds. Of the rheumatic neuralgia, we know not, as yet, material changes.

Rheumatism of the Stomach.—Before all, I beg to remind you of what I said in a former lecture on *febrile gastric disorder*, *i.e.*, functional derangement of the abdominal organs arising from troubled innervation by any kind of paroxysm. This, therefore, is a familiar companion of rheumatic fever too, and requires simply patience until the crisis carries it off, or the use of an emetic and purgative, according to signs and indications, pointed out in the place mentioned. But there may be, instead of common febrile derangement of the abdomen, rheumatism localised in it, in which case the above remedies would cause great mischief to the little sufferer.

Rheumatism of the stomach, as far as I observed it, on grown-up people, causes from time to time fearful constrictive pains of that part, with the utmost intolerance of food, cold water, and remedies. The pain is commonly remittent, and if continuous, then it will, at least at intervals, increase for a short time. The epigastrium is tense, and resists but little pressure. There is much thirst, but only small quantities of liquid tolerated, rather warm. All these symptoms can be more or less severe. The tongue is proportionally less red and dry than in the erythematous, or (the very rare) general inflammation of the stomach. I have observed in some well ascertained cases of rheumatic fever, with rheumatism of the stomach, a dry red stripe, from half an inch to an inch broad, of a very striking aspect, like a ribbon, from the top of the tongue to the bottom, just along its middle third, and the other two thirds outside more or less approaching the normal aspect. This I have observed also on some children, but not of the tender age. I cannot say that it is quite peculiar to rheumatic fever, and therefore of much diagnostical value.

I think I am right in drawing the following proportional relation between local symptoms and fever, in gastritis and in rheumatism of the stomach. In gastritis, the acuteness of the attack, the pain of the stomach, and dryness of the tongue, are in proportion to the degree of fever.

In rheumatism of the stomach, the pain may be very intense, with moderate or little fever, and a moist tongue. Now this is of some value, though not without exceptions. No doubt, it is of the first importance to know real inflammation, be it primary or arising from acute rheumatism of that organ. In about twenty-four hours this becomes clear; under that time, if in high fever you find the child vomiting, with tense epigastrium, a lively expression of pain in the countenance, and continuous painful moaning, instantaneous increase of those symptoms, by a painful outcry of the child, as soon as you press with your finger upon the epigastrium; if all these are present some hours, and cease not under suitable warm poultices, it would be a fault to wait longer with energetic antiphlogistic means, and expose the child to the possibility of danger by delaying until the fever, and along with it the gastric affection, might show its real nature.

Rheumatism of the liver, having its seat in the serous envelope of this organ, causes painful moaning under the respiratory movements of the chest and diaphragm, bilious vomiting and similar diarrhoea, and is easily discoverable by carefully touching over the liver. I believe most of those cases, which in the first years of my hospital practice I have called "hepatitis," were but rheumatic affections of this organ, only a few of which had the inflammatory character.

Both *rheumatism* and *rheumatic inflammation* of the intestines are rather common in children, even of the tender age. Rheumatism in these parts, connected with fever, can scarcely be overlooked; besides a continuous uneasiness, and painful expression of countenance with moaning, from time to time the pain increases so far as to cause vehement painful crying, with the usual drawing up and moving of the legs, then usually comes a sudden diarrhoea of thin serosity, a little yellowish in nurselings, above that age not unfrequently greenish. After these tumultuous evacuations the child becomes more quiet, but appears still uneasy, the belly is puffed up and tender on pressure. If the affection be inflammatory all these signs are more strongly expressed, and the expression of pain itself almost unremittingly strong.

In *peritoneal rheumatism* the more puffed state of the belly, with exquisite tenderness all over its surface, will soon discover the seat of pain. Serous diarrhoea and most of the before-mentioned symptoms will be present. I believe in fact, that the abdominal peritoneum may merely be affected in this way, without involving the intestines. As to the question,—Whether the seat of rheumatism be in the serous or muscular, or both envelopes of the alimentary canal? I believe that it can take place in all or any of them; but to make a distinctive diagnosis between the affection of either coat is, I think, as impossible as useless.

I remember an old and respectable colleague of mine expressed strong doubts as to the possibility of diagnosing the abdominal seats of rheumatism in a child affected with fever, because the child, he said, is so irritable, and feels so much tenderness all over its body from the fever itself, that at a moderate pressure by your hand it will show great irritability, with some expression of pain, and not bear the touch, even if there is not the least degree of pain or irritation present. Similar remarks I may be allowed to state, arise from superficiality, which may be carried with us to the grave.

There is no doubt that there will be instances in which we cannot make out the seat in the first twenty-four hours, or whether it be simple rheumatism or beginning gastro-enteritis or peritonitis; but these, (in which, however, a good practitioner will know what to do), are not frequent for him, provided that he be skilled in children's ailments. It is also of importance not to overlook, under the recent primary paroxysms, those inflammations. Now in this respect. I can assure you that a young child affected by any high paroxysm, lies down-cast, depressed, heavily moaning, with half-shut eyes; and if in this state you press upon the belly, there will be expression of acute pain, by vehement outcries, only in the case of real significant pain; under other circumstances, the child in fever will scarcely notice your touch.

Rheumatism of the hip-joint, I very seldom saw connected with strong fever; it appears more frequently in the chronic form, and never, as I am aware, before about the sixth year, when it will be easily diagnosticated.

Now, I have finished that short review of *rheumatic local affections*, each of which can exist merely as pain—fixed, or erratic, leaping from one part to the other—or pass within the first day or two into inflammation. In my next lecture, I will try to give you more exact practical directions on the rheumatic fever in its different connections with the described local affections.

INTRODUCTORY LECTURE,

DELIVERED AT THE

LEEDS SCHOOL OF MEDICINE,

OCTOBER 4TH, 1852.

By THOMAS NUNNELEY, Esq., F.R.C.S.E.,

President of the School for the ensuing year.

Printed by desire of the Council of the Leeds School of Medicine.

GENTLEMEN,—My friends and colleagues, who form the Council of the Leeds School of Medicine, having done me the honour to elect me to the office of President for the present year, it becomes my duty, in accordance with a custom which has for some period prevailed amongst us, to deliver the introductory lecture of the session, which is now commencing. Before, however, formally entering upon the immediate business of the day, I would in their names, as well as in my own, beg to

congratulate those of you who do not now meet for the first time in this room, and to greet with a welcome those whose first appearance amongst us is this day made. To the former I would express the hope, that the period which has elapsed since we last met has not been wasted; that though the more regular and direct studies may have been interrupted, the important object of them has not been forgotten; that, while leisure and time have been afforded for recruiting health and energy, which are apt to become somewhat languid and impaired by a long course of study; that, while the vacation has offered to many of you opportunity, in country retirement, for renewing, or making acquaintance with many objects of natural beauty and interest; or by travel, of introducing to your notice the wonderful creations of man's genius, industry, and mechanical skill, in the various productions of art and science, with which our own and other countries abound; yet that the information gained, and the labour expended during the last or former sessions, has not been lost or forgotten, but that you now assemble with renewed energy and zeal to start from the vantage ground you then won; and endowed with a firm resolution, which shall continue throughout the whole session, to make such further progress as shall be creditable to yourselves, satisfactory to your teachers, and commensurate with the advantages you have and will enjoy. To the latter class of my hearers—those who now appear within these walls for the first time, I would say with encouragement, let not difficulties which you will inevitably encounter, affright or dismay you; turn not away in disgust from questions, that to you will necessarily appear abstruse, because you see those who sit on the same benches with yourselves, make no difficulty of them, but remembering that not so long since they were in the same position as you now are; rather let the fact of those who have had the advantage in the start of you, having advanced before you, prove to you that the ascent is not insurmountable, and that ordinary diligence and due perseverance will be rewarded with satisfactory and pleasurable success. Thus let me express the earnest hope that the good resolution which I doubt not you have all formed, may, by your intercourse with each other, be mutually strengthened and encouraged—that a just and honourable emulation may be felt and fostered amongst you, so that if any tendency to idle or improper habits should be evinced, as amongst a number of students may perchance be the case, the general tone and feeling of the great number shall be so decidedly felt and expressed, as to overcome and destroy the feeling, and that the high reputation of the students of the Leeds School of Medicine, for good conduct, for persevering industry, and for great professional information, which has been so generally, and I believe with very few exceptions so deservedly, awarded to them, shall not only be maintained, but increased; that at the close of the present session we may fairly claim a place in the foremost rank of medical schools, whether they be provincial or metropolitan. For, remember, and it is a fact which can never be too prominently brought before the minds of students, that be the talents of the teachers

ever so great, or the means and appliances of the place of education unsurpassed, the permanent reputation of the school, college, or university, can only be maintained by the character and acquirements of those whose education has been received, and whose characters have been formed, within its precincts. Let, therefore, each student who is now assembled within this room, so feel and act as though the reputation of the school depended upon himself alone.

During the last few years, a considerable change has taken place, not only in respect to the style, but also as regards the matter of the introductory lectures. Formerly an introductory lecture would have served equally well, not merely for any of our prescribed courses, but indeed, for almost any academical course. Latterly however, this practice has been by many persons abandoned; preliminary remarks, as though unnecessary or useless, have been by them almost entirely avoided, and instead, the direct subject of the course has been abruptly introduced. This change of fashion is not confined to medical concerns, but has extended to almost every affair of life, and is, indeed, one of the many proofs of the altered taste of the age, which is, as it is pleased to style itself, practical. During the last century the elegancies rather than the utility of things, were considered; at the present time it is exactly the reverse. *Cui bono?* What is it good for?—where does it lead to? are the queries which are made in every quarter.

While, however, we may readily admit the comparative inutility of a lecture, the only purpose of which is to introduce the teacher and the pupil to each other, instead of to the subject as well, be permitted to doubt, if the abrupt entering upon the mere details of a course of study in any department of science, be the most advantageous method which can be pursued. In my opinion it is not. In all cases it is better that the student should have placed before him something like a general view of the objects to which his attention is about to be directed, and the end which his labours should always have, as their beacon, ought to be clearly indicated; because, unless we distinctly comprehend the great principles which the details of a long and laborious course of study should enable us to understand, our progress will be wearisome and tedious, our reward meagre and unsatisfactory. Instead of being thinkers, reasoners, and philosophers, which, in the highest sense of the term, every medical man ought to be, we shall be mere mechanical artisans, or empirics, totally incapable of comprehending “the height of our great argument,” sink down into mere rule of thumb practitioners, with all the ignorant prejudices of mere routine and habit, doing things merely because they have been done so, incapable of perceiving the advantage of advancing scientific skill, and unwilling to adopt new remedies, or modes of treating disease, simply because they are new; or, what is worse still, because far more mischievous and dangerous, we shall be liable to become the sport of every specious scheme, the followers of every new doctrine, the dupes of any plausible knave or fanciful dreamer, until, being unable

to discriminate between true liberality of mind, and genuine freedom of action and thought, and that bastard liberalism which would destroy what exists of thought and action, merely because it has existed, and we shall end in a general distrust of every doctrine, and in being disbelievers in the plainest evidences of our senses.

Though some of the remarks which I may make have a bearing upon the whole of your professional education, I must not forget the individual course which we have now entered upon, to which this must especially be considered the introductory lecture, and to which, in concert with my colleagues, I shall have to direct your attention, and shall, therefore, now proceed to place before you some slight, and (from our time) necessarily very imperfect, sketch of the objects of the anatomical course. The importance and extent of the subjects included within this course is at once most decidedly marked by the simple fact, of those governing bodies who have the control of medical education, so long as a particular length of course was enjoined, having required more than double the number of lectures than was required in any of the other sections—an extent which, though the precise number of lectures is now left to the discretion of the teacher in each course, the nature of the subject still compels. I must, therefore, beg to impress upon you the importance of the task; and while I would by no means wish to exalt one department of our common labour at the expense of another, or think that any one can be called a well-informed medical man, who has not attended zealously and thoughtfully to all, yet, I am sure my friends who are about so able to conduct your studies in other departments, will fully agree with me when I say, that if there be one section upon which you should devote more time and attention than another, it is upon anatomy, since with its relatives and dependents, indeed I might justly say necessary sequents—physiology and pathology, it forms the only solid basis upon which you can hereafter rest in practice. It is to medicine which the foundation stone is to the superstructure; or, to use a simile, which, if not very eloquent, is at least, on this occasion, as you will hereafter, on a more intimate acquaintance with the matter admit, apposite. It is the vertebra or back bone of scientific medicine.

All objects are arranged into two grand divisions,—those which possess separate organs, and are endowed with a property which has been universally denominated vitality, and those, the individual particles of which are agglomerated into masses, without any distinction of parts, and not being endowed with vitality, are called inert. Upon what this difference essentially depends I do not propose to enter, interesting and important as it undoubtedly is, because it would lead us too far from our immediate business; and, moreover, it is of somewhat too abstruse and speculative a character, to be fully understood in the present stage of your studies. Now, to the whole of the first of these very large divisions, the term anatomy is properly applied, when we proceed to examine the structure of the separate organs of which each object is made up; you thus see that it is one of very great comprehen-

siveness, and necessarily requires many divisions and subdivisions. The first of these will naturally and obviously be, into *animal anatomy* or *ZOOLOGY*, and *vegetable anatomy* or *PHYTOLOGY*. It is only within the last few years the latter division has been much cultivated, and not until within our own time that its importance has been fully recognised. Formerly botanists, for the most part, contented themselves with an examination of the external parts of a plant; now, however, the minute internal organization is that which deservedly receives the chief attention, and the most profound and careful investigations have been, and now are, carried on by men who are in every way qualified to conduct them to a successful issue. Every true physiologist will hail their labours with gladness, inasmuch as they have a most important bearing upon animal physiology; every discovery in the one cannot fail, directly or indirectly, to advance our knowledge of the other. Indeed it appears highly probable, that it is to the prosecution of vegetable anatomy and physiology that we must look for the solution of more than one problem in animal physiology, which yet remains unsolved. Since not only are we here presented with organization in a simpler form than it is in many animals, but with vitality of a more enduring character, so that we are enabled to regard its different phases, and, in some degree, to control its manifestations, in a manner that would be quite destructive to that of most animals. The investigations of Schwann and Schleiden, with the assistance of those who have followed in their steps, have led to speculations and generalisations which, could they by possibility have been a few years ago conceived of by the wildest imagination, would have been regarded as unreal as the “baseless fabric of a vision;” yet, how important are the results to the physiologist and pathologist of the present day; and who shall say how much more important they may not hereafter (and that, possibly, at no distant day,) become in our treatment of disease?

Animal anatomy is subdivided into human anatomy and comparative anatomy. The first, as the name indicates, treating of the structure of man; the second, that of other animals: the term “comparative” having been applied in consequence of its having been instituted for the purpose of comparing the structure of brutes with that of man. Indeed, in former times, when the prejudice against human dissection was greater than it now, happily, is, animals were not unfrequently substituted for man, as was the case with Galen, who is said to have derived his knowledge of anatomy principally from the dissection of apes. Now, although as medical men, whose business it is to alleviate the suffering of our fellow-creatures, of course it behoves us especially to become acquainted with the details of our own formation; and consequently that our attention, particularly in the younger student, should be principally directed to descriptive human anatomy; yet, let me impress upon you the necessity there is of making constant reference to the structure of animals inferior to ourselves in the graduated scale of creation.

Anatomy, in its strict etymological sense, merely

signifies a knowledge of the structure and configuration of organised bodies; but were our inquiries to rest here, though the extent of our information might be great, it would be almost valueless. It is true, that after death the dissecting knife will reveal to us numerous parts endowed with a delicacy of structure and beauty of arrangement perfectly surprising, as well as show us most dissimilar textures and shapes arranged in a constant and uniform order and relation to each other. Yet it is more than probable were our observations to be limited to the body deprived of life, the mind would be bewildered and confused with their seeming complexity and intricacy. But let us set this body in motion, and regard the same parts while performing their various functions, all feeling of confusion and complexity instantly disappear, instead of which a sense of delight seizes the mind at perceiving the uses, and mutual dependencies, and adaptation of these parts, of which previously no conception could have been formed. It is this knowledge which constitutes *PHYSIOLOGY*, or the study of the cases and functions of those parts the structure of which *ANATOMY* reveals to us. Hence we see the inseparable dependence the one has upon the other; a connection so intimate that it can never be discovered, since the mind absolutely refuses to contemplate organs variously arranged and united together, without immediately dwelling upon the purposes of such arrangement. This propensity of the mind to pass immediately from the structure to the use of a part is evinced even when regarding a piece of inanimate machinery, when the question,—“For what purpose has this instrument been constituted?” is directly suggested.

Nor is this innate desire of the mind merely a matter of speculative curiosity; it is of the highest importance to us as medical men. Interesting as a contemplation of all means towards an end, and a knowledge of the methods by which the various purposes of organic life are accomplished, must undoubtedly be to all, yet upon us this has still higher and peculiar claims. It is our office, as I have just said, to remove or mitigate disease and suffering. In what do these consist? Simply in the cessation or irregular performance of the functions of the different organs of the body. As perfect health results from the perfect performance of all the natural functions of the various organs of which the animal machine is made up, so do disease and pain result from an alteration in the structure and functions of these parts.

To obtain an absolute and correct knowledge of the precise function of every organ of the human body is, however, by no means an easy task. Placed, as man is, at the head of terrestrial things, and endowed with faculties and powers of a higher and more perfect order, which result from the greater development of some, and the more intimate and mutual dependence of all the organs of his body upon each other, he, for this very reason, is, perhaps, the least adapted for presenting to us these functions in an isolated and separated form; inasmuch as he is, on this very account, susceptible of such varied emotions from so many causes; and, from their subserviency and relation to each other, derangement in the function of one organ so frequently leading

to disorder in those of another viscus, that he is affected by circumstances which produce little or no change in animals whose structure is of a more simple character. So that it is more than probable, had a knowledge of physiology been solely derived from a contemplation of man's organization, it would have been much less in amount than it is at the present day.

Although it is only within a very recent period that the immense importance of *COMPARATIVE ANATOMY* has been fully recognised, fortunately the cultivation of it has never been entirely neglected, and long before its intimate bearing upon the science of physiology was perceived; it was the means of making known many of the brightest and most important discoveries which adorn the annals of our own or of any other profession. Of these I will only enumerate a few.

It was by dissections and experiments performed upon the lower animals, that the immortal *HARVEY* was enabled, early in the seventeenth century, to make the glorious and memorable discovery of the circulation of the blood—a brighter than which no science can boast, whether we regard the strictly philosophical induction of which it was the effect, or the important consequences which have resulted from it. It was while examining the mesentery of a live frog, in 1622, that *ASSELLIUS* discovered the lacteals; nor was it until twelve years afterwards that *VESLINGIUS* showed their presence in the human body. Whilst in the act of examining the viscera of a horse, *EUSTACHIUS* first discovered the thoracic duct; and shortly afterwards, in 1651, from observations made upon other brutes, Pecquet ascertained its use. It was *SWAMMERDAN*, who, as is well known, pursued comparative anatomy with such untiring zeal, and first pointed out the presence of valves in the absorbents; and it must be familiar to all, that it was whilst dissecting a frog in 1790, *GALVANUS* first discovered the existence of that surprising agent, which has been named after himself, an agent which from that time to the present has never ceased to occupy the attention of some of the greatest minds of every civilized nation; and which has done more to annihilate time and space;—to give man true power;—to subject the elements to his control;—to make mind supreme over matter;—to endow man with such power and importance, that the wisest of the nations of old, with all their presumption, never conceived of attributing to the greatest of their most dreaded or their most honoured deities; but of which we now avail ourselves to send our hopes and fears, our commands and our aspirations, over the land, through the air, and under the ocean. And while it is the winged messenger of our wants and wishes to the farthest corner of the world, it is not improbable that the self-same agent which connects in wondrous sympathy the various parts of our own microcosm, and enables man's intellect and volition to reign supreme over, not only his own members, but over all created things; and which, both in health or disease, whether identical with, a modification of, or an analogous power with that generated by the nervous system, deserves, and will receive, from every enlightened mind, the most careful and continuous study.

These examples of brilliant discovery, were they isolated and alone, would be sufficient to stimulate us to cultivate an acquaintance with this study, but they by no means institute the most important feature in the connection it has with human anatomy. Since comparative anatomy has been pursued in a more systematic manner, it has led to what is called DEVELOPMENTAL ANATOMY, that is to say, to an examination of the order in which the different organs are produced, and the relative proportions to which they bear to each other, by which most interesting and important facts and conclusions have been demonstrated.

First. That the whole organized world is intimately connected by laws which are of universal application, and that, at least, as far as regards the animal kingdom, there is a connected series, in which the change from the lowest to the highest, are marked by such very gradual and progressive alterations, that we are enabled to trace every organ from its simplest and most elementary form up to the highest and most complicated arrangement, of which it is susceptible, clearly showing, that if we wish to understand the structure and use of it in the latter condition, it must be by careful examination of it, in its first and intermediate forms.

Secondly. We have demonstrated that the condition of man himself is not a permanent and unchangeable one through all the phases of his existence, and that he does not at every period occupy the same elevated condition which he assumes in the adult state; on the contrary, we have shown that he passes through almost every grade, as well in structure as in habit, which we see to be the permanent condition of other animals. Thus I am not drawing upon the imagination, or stating more than a literal fact, when I declare, that in the earlier periods of foetal life he bears a much closer resemblance to a fish or the tadpole, than he does to the intellectual being of manhood. If we proceed in the examination, and trace him onward in his improving career, we find that this similarity is not confined to one set of organs, but that it is common to the whole system; and that, as these in their growth, and progress in development, assume a different configuration, they present to us an almost exact resemblance, or even identity, with the permanent condition of the same organs in the adult animal of the lower grade, from which is clearly to be deduced the grand fact, that in the formation of the animal kingdom, one common, simple, and magnificent plan has been laid down for the whole,—that, diversified and various as are the functions and habits of all these numerous and dissimilar creatures, yet the arrangement and organization in each is referable to the same general standard of formation, in which, by slight modifications, and increased development in one or other, or in all of the organs, the myriads of different races are produced.

In order to illustrate this I might take every part of organised beings, and might show you how the complicated skeleton of man is gradually to be traced from a simple vertebral column; and how the individual bones of the column consist of nine primary portions or elements,—the cyclo-vertebral; the two peri-vertebral,

which encompass the spinal cord; the two epi-vertebral, forming the superior spinous processes; the two para-vertebral, which protect the large artery and vein; and the cata-vertebral, which constitute the inferior spinous processes; showing that as the relative position of these elements with regard to each, is altered—that as one or other of them is developed, so do we find the entire form of the animal change, the cyclo-vertebral alone remaining constant. In the head the peri- and epi-vertebral elements are largely developed to form the cranium for lodging and protecting the brain and medulla. In the body the para- and cata-vertebral are developed to form the ribs, for supporting the thoracic and abdominal viscera; while, according to the part of the column where this development takes place, do we find a great modification in the whole animal. In fish it is towards the anterior part of the column, leaving the tail free for giving the necessary impetus in swimming; in birds it is towards the posterior part, leaving the neck free for the necessary motions in these creatures; while in quadrupeds it is in the middle part, as most convenient, where the body is equally supported by the four legs. So might I go through, did our time allow, the whole alimentary and digestive apparatus, by which new material is received into the body; the circulatory, which so immediately sends the nutrient fluid to all parts of the body; the respiratory, in which that fluid is so extensively brought into contact with the air, forming a far more perfect warming apparatus than man probably will ever invent; or I might take you over the most interesting of all our organs—the nerves, and show how the great brain of man is almost imperceptibly developed from a small white circular cord, no thicker than a fine thread. But I must rest contented with showing you the contrast between the highest and lowest forms in these organs. The filling up is the work of the session, each series will be brought before you in due succession, and as the consecutive links of the harmonious chain are unravelled, you will appreciate the truth of what is now asserted.*

By thus tracing upwards the gradual increase of, and addition to parts, and simultaneously observing the kind and extent of function exhibited by their possessors, ascertaining whether, and to what extent, the organs of man in their process of development resemble those of brutes, we are enabled to arrive at a satisfactory knowledge of the uses of their various parts by a synthetical method, which must not only be far more complete, but far more certain, than any information which can be derived from rudely lopping off portions of the more complicated viscera of fully-developed and adult animals can possibly be.

[To be continued.]

*These remarks were illustrated by a great number of preparations and diagrams, in which the various parts of the osseous system,—the organs of digestion, of circulation, respiration, and the nervous system, were shown in their progressive development, from the most simple and elementary forms, up to their most complicated arrangement; Mr. Nunneley giving a rapid and general description of them, and inviting those assembled after the lecture, more minutely to examine the illustrations for themselves.

CASE OF URETHRO-VAGINAL, RECTO-VAGINAL FISTULÆ, AND CALCULUS VESICÆ.

BY SILAS PALMER, M.D., NEWBURY.

On the 24th of May, 1851, I was requested to visit Sarah G., aged 26, unmarried, servant.

History.—That she was confined (being primipara) in London without assistance; the child still-born. That, after the labour, sloughing took place, and she was compelled to seek advice at one of the metropolitan hospitals, in which she remained three months, and at the expiration of that period was dismissed as incurable. Since then she has continued to suffer from the constant involuntary escape of urine and fæces, which passed through the vagina, and so distressing was her state on this, my first visit, that she was unable to move beyond her bed, or bed-chair, from the intense pain and uneasiness produced by the irritating and offensive discharges. On examination I found the external genitals immensely swollen, excoriated, and smelling most disgustingly. On introducing a speculum, I discovered that fistulous communications existed between the rectum and vagina, and urethra and vagina.

Treatment.—I carefully cauterised the margins of the fistulous apertures with nitrate of silver, and adapted a vulcanised India-rubber apparatus to collect the urine, and prevent excoriation, and at the same time filled the vagina with lint, smeared with an ointment composed of iodide of lead, glycerine, and cod-liver oil. Pills of the iodide of iron and hyoscyamus were nightly administered. The fistulæ gradually closed, and in three or four months she returned the apparatus, as she deemed herself nearly well. After the lapse of ten months she again applied to me, having walked a distance of three miles. She complained of excessive irritability of the bladder, severe pain during micturition, agonising suffering after the discharge of urine from the bearing-down of the rectum, uterus, and bladder. Suspecting that stone in the bladder existed, I immediately examined, and found the orifice of the urethra very patulous, and the mucous membrane everted and excoriated. On sounding I discovered a large calculus.

Dr. J. Bunny, at my request, then visited her, and most kindly assisted me in the further treatment of the case. Hoping that I might be enabled to remove the calculus by dilatation of the urethra, I introduced compressed sponged tents, and continued the process by Weiss's dilator. The patient complained so bitterly of the pain, and there being comparatively but little progress made, owing to the contracted state of the passages from cicatrices, and the size of the stone, determined me to have recourse at once to crushing, and for that purpose I employed Professor Ferguson's lithotrite. By giving a smart blow on the side of the pelvis with the open hand, in the manner recommended by Sir B. Brodie and Mr. Skey, the calculus was soon seized, and broken, and on washing out the bladder a quantity of mucus and detritus escaped. The

operation was repeated several times, a greater period being occupied in the treatment owing to the reappearance of the catamenia, which had been suppressed since her confinement. By the previous dilatation she was enabled to void some large pieces, one of which weighed two drachms; this was attended by a considerable amount of hæmorrhage. The fragments altogether removed and collected weigh seven drachms and a half, and the fine detritus, (much of which escaped,) was unfortunately permitted to pass uncollected. The calculus was composed of the phosphate of ammonia and magnesia. The bladder, both before and after each operation, was carefully injected with warm water, and an hour after she was placed in a warm bath, and sedatives given.

On the 22nd of July I last visited her. The examination then instituted convinced me that the bladder was entirely free from calculus or detritus, and the cessation of all the unfavourable symptoms confirms me in this opinion, and gives me the satisfaction of pronouncing my patient as completely freed from her distressing ailments. Since the above date I have heard that she is still going on well, that she has been at work in the harvest field, and that she retains her urine perfectly.

Speenhamland, Newbury,

September 10, 1852.

Hospital Reports.

WEST NORFOLK AND LYNN HOSPITAL.

CASES ADMITTED UNDER THE CARE OF CHARLES COTTON
M.D., F.R.C.S., SENIOR SURGEON TO THE HOSPITAL.*

Stone in the Bladder—Lithotomy—Death in thirty-six hours.

GEORGE GOSLING, aged six years and a half, son of a corn-porter, admitted May 15, 1852. Described by the mother as "a pensive ailing child from infancy, though always hearty at his meals." Was treated for worms about three years ago, when he first began to complain of pain and aching at the lower part of the stomach, and across the back and loins, together with itching and smarting at the extremity of the penis before and after passing water. The bowels have been relaxed from birth, and the urine has been seen occasionally to deposit a reddish-coloured sediment.

Suspicious of urinary calculus were first entertained during the last winter, on observing the patient to make three or four painful and ineffectual attempts before he was able to pass his water, and this latter symptom had gone on increasing so much in severity, that up to the time of entering the hospital, he would often cry for upwards of half an hour at each period of micturition.

* Concluded from page 506.

The influence of chloroform having been completely induced in spite of considerable resistance on the part of the patient, a calculus of moderate dimensions was readily detected with the sound, and rendered audible on being struck. The urethra being tolerably capacious and calculus small, the want of an applicable lithotripsy instrument was much regretted.

Boy sick and ill all day and night following the sounding, from the effects of the chloroform. To have middle diet and to remain undisturbed ten days or a fortnight, to familiarize him to the hospital and his attendants.

May 31st.—Improved in condition and appearance; complains less in passing water, which he has been instructed to do whilst on his back in bed. Again sounded in consultation, but without a resort to chloroform, as he much objected to it. Some little impediment experienced on entering the sound, owing to the elongated and thickened state of the prepuce. The presence of calculus not being unanimously established, lithotomy only conditionally sanctioned.

June 2nd.—Bowels very freely moved three times from an injection administered early this morning.

1 P.M.—Patient quickly and effectually placed under the influence of chloroform by Dr. Black, house-surgeon, after the Edinburgh method, and a grooved staff introduced; during the passage of the instrument a further copious liquid evacuation escaped from the bowels. The stone being now satisfactorily evident, the operation was proceeded with by making with the knife a free external lateral section, and afterwards cutting into the groove of the staff, taking care not to open the urethra too far forwards; then substituting a small cutting gorget, and cautiously feeling its beak sliding upon the surface of the staff, the division of the prostate and neck of the bladder was gently effected in the usual way, a gush of urine following the entrance of the instrument; the internal incision having been still further dilated by the fore-finger, a pair of curved forceps was introduced, when an encrusted calculus, of mulberry formation, weighing two scruples and a half, was at once seized and withdrawn without difficulty. The boy was then conveyed to bed, still under the influence of chloroform and quite unconscious of the operation, which had occupied but a very short time. A slight oozing of blood from the wound was restrained by the application of matico.

Evening.—Quite comfortable and easy for upwards of two hours after the operation, when purging commenced; the patient makes no complaint, but lies in a drowsy state, breathing quickly; face of a dusky hue, and skin profusely perspiring; pulse 120; tongue clean; there is no tenderness of abdomen, but frequent spinage-coloured, slimy, frothy stools, escape from the bowels. *Symptoms attributed by Mr. Cotton to chloroform.*

3rd.—Has had lead and opium, aromatic confection, logwood, starch injections, &c., but there continues a succession of watery evacuations from the bowels, which nothing can check; urine dribbles away by the wound; the boy lies in a motionless, comatose state, as if under

the influence of some narcotic poison; the breathing is hurried and heavy; pulse rapid; face congested; eyes suffused, and pupils dilated. He appears sensible on being roused, but immediately relapses into a state of stupor. Ordered hot stupes to the abdomen.

Various opinions hazarded in explanation of the boy's symptoms,—chloroform, shock, inflammation of intestinal canal, internal hæmorrhage, &c. The operation was allowed to have been performed in the most perfect way. The improbability of hæmorrhage, from the symptoms present, was immediately confirmed by passing the finger through the wound, giving issue on its withdrawal to two or three ounces of clear urine, and two small coagula. No blame, it was warmly contended, could justly be attributed to the chloroform, as the symptoms, diarrhoea and stupor, were unusual, and did not come on until some time after the patient had been placed comfortably in bed, and had recovered (apparently) altogether from its influence.

Evening.—Weaker and weaker; sinking gradually. Death just after midnight.

Examination twelve hours after death.—Some diffused congested patches upon the chest, abdomen, and extremities, and great lividity of the depending parts of the trunk. Lungs, posteriorly and inferiorly, much congested. Right kidney double its ordinary size, its cortical and tubular structure darkly congested; the left useless, and almost completely wasted. Bowels contained but a small quantity of liquid matter; the mucous surface pale and bloodless; bladder hypertrophied and contracted, but otherwise healthy and without a blush of vascularity. The internal incision marked by an unimportant congested condition, found of limited extent, and not exceeding the boundaries of the prostate and neck of the bladder. The walls of the rectum in proximity with the wound darkly congested.*

General conclusion.—Diarrhoea, stupor, and nervous shock, consequent upon the operation, the wasted kidney though evidently the result of disease at some former period, being immediately connected with the cause of death.

REMARKS.

Number of males cut by lateral method, at all ages and under varied circumstances including father and son, 13. The youngest four years old, from whom a calculus weighing two drachms ten grains, was extracted. The eldest 67 years, weight ten drachms and a half.

Number of Calculi.—Single in eleven cases, two in one, and three in another. Minimum weight two scruples and a half; maximum one ounce and a half. Reproduction of stone in one case after lithotomy, and in another after lithotripsy.

Complications.—In the case of lithotomy a second time, the first division of prostate by the gorget insufficient, right lobe therefore divided by a probe-pointed

* In conducting the examination a trifling slit was made accidentally, with the scissors, in the rectum; the occurrence, though unimportant, is noticed to complete the report, as it was afterwards singularly alleged by a witness to have been a fault in the operation, and the probable cause of diarrhoea and death.

bioury. In a second case, that of Hisgate, a fusible calculus crumbled to atoms within the grasp of the forceps, and was partially removed with the scoop and warm water injections. In the third case, that of Leonard Garner, a brittle oxalate calculus, weighing one ounce and a half, broke up into thirteen fragments, one of which was only detected and removed with the forceps from the bladder after placing the patient in bed.

Result.—The ten first operated upon recovered, the remaining three died. First, Jary, aged 35, on the fourth day, from secondary hæmorrhage; second, Kemp, aged 67, a very unfavourable subject, case of triple calculus, on the twenty-ninth day, from exhaustion; and the third, Gosling, aged six years and a half, in thirty-six hours, diarrhoea and stupor supervening.

The instruction derived from witnessing and assisting at numerous lithotomy operations, including two in which no stone was found, conducted with the gorget, beaked knife, or common scalpel, led in each case to the employment of the cutting gorget, as the safest and best instrument in not over experienced or dextrous hands, to insure limited incision of the prostate and neck of the bladder, a point of the first and very highest importance. The blunt gorget or finger served as a dilator of the wound, and in each instance, where an elastic tube was not left in the bladder, the finger was gently passed a few hours after the operation to lessen the danger of urine becoming effused into the pelvic cellular tissue. Since the practice of lithotripsy and the more frequent use of the catheter-forceps,* operations for lithotomy appear to have become comparatively more rare in this district. The five cases just reported, commencing with that of Stanfield, include the whole number lately performed at the Lynn Hospital.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

MAY 6TH, 1852.

J. HADLEY, ESQ., IN THE CHAIR.

Fracture of the Neck of the Femur.—By MR. MOORE.

THE subject was an old man, who died from debility and the irritation caused by the accident. The fracture, contrary to the generality of such cases, is both within and without the capsular ligament, involving the large trochanter, neck, and small trochanter. The case was diagnosed by the shortening present, the eversion of the foot, and crepitus. The accident was caused by indirect violence.

Fibrous Tumour involving the Cerebellum.

By MR. MOORE.

This preparation shows a fibrous growth, having its origin from the cerebellum. It passes more to the left side, and the cerebellum itself was found pushed upwards

against the tentorium, very soft in structure, and containing bodies resembling, under the microscope, ill-formed pus globules. The tissue of the tumour itself appears, under the glass, to be composed of fibres radiating in various directions, with a scattering of nucleated cells. The subject from which the preparation was taken was a man, aged about 40, who had long suffered from anomalous symptoms, referrible to the head. When admitted into the hospital there was *very marked spinal gait*; and he complained of shooting pains, particularly at night, in the regions of the ears and forehead. He never complained of occipital pain. He remained under treatment some weeks, until his death, there being no change in the symptoms, dissolution being preceded by great debility, and consequent inability to walk. He had always lived a moderate life, and never received a blow or other injury of the head.

Separation of the Frontal from the Parietal Bones, with Depression of the Left Parietal.—By MR. MOORE.

A man fell from a horse as he was proceeding at a somewhat rapid pace, and struck his head on some hard stones. On being seen an hour afterwards, the whole scalp was found much swollen, but by careful manipulation depression was found to exist near the left frontal suture. As the man was comatose, with dilatation of the opposite pupil, an incision was made through the scalp, and the depressed bone brought to its proper level. The immediate effect of this was relief of the stertorous breathing, and much less amount of dilatation of the right pupil; death, however, took place some fourteen hours after, and a large amount of blood was found extravasated both above and beneath the dura mater, with laceration of its structure, and also of the cranial substance in one place. The preparation shows the line of fracture and the depressed bone.

Ascaris Lumbricoides Ejected by the Mouth.

By MR. MOORE.

This is one of a common variety of worms, but it is worthy of notice that it was passed by the mouth. The subject was a lad, aged 14, under treatment for a fractured humerus. He was suddenly seized with cough and sensation of choking, which continued at intervals for some time. Ultimately the worm passed into the mouth, and was pulled from that cavity by the lad himself. It was thought the paroxysms of cough were due to nuts he had been eating.

Remarkable Case of Double Strangulation of Small Intestine.—By MR. SIMONS.

On October 2nd, 1851, at nine P.M., Mr. Simons visited a boy aged 4 years. Learnt that on the day previous the child complained of pain in the abdomen, and had vomited his food. The mother had given him some castor-oil, which was returned soon after; nor did any fluids taken remain on the stomach.

When seen at nine P.M., the countenance wore an anxious appearance; the eyes were much sunken; tongue furred; skin hot and dry; much thirst; bowels

* See the case of Fisher, *Provincial Journal*, p. 421.

not relieved since the 30th (two days since); there was no swelling, nor any perceptible tenderness of the abdomen; pulse quick, jerking. Gave Cal. c. Jalap. utrq., gr. iv., and febrifuge mixture every three hours.

3rd, ten A.M.—The child worse. Bowels not acted; frequent vomiting of the fluids swallowed. Gave Cal. c. Jalap., gr. iij, every two hours, and administered an enema, which returned in the same state immediately.

Five P.M.—In the same state. Slight tenderness of the abdomen. Ordered hot fomentations and repeated enema, without effect.

Eleven P.M.—The same.

4th, nine A.M.—Worse in all respects. Vomiting constant; bowels not moved. Gave a warm aperient every two hours; repeated enema, without effect.

Five, P.M.—Much worse. Ordered wine and water frequently.

Eleven P.M.—The same.

5th, nine A.M.—The child was evidently sinking. Extremities cold; muttering delirium; focal vomiting; bowels not yet opened; takes nothing but wine and water, which returns.

Five P.M.—Still worse. He continued in this state until eight P.M., when death terminated his sufferings.

Section-Cadaveris.—A very remarkable double strangulation of the small intestines existed; it was formed in the following manner:—A knuckle of small intestine adhered closely to another portion of small intestine, apparently close to the root of the mesentery; this second portion of intestine passed under the adherent part of the first portion, at about four inches from the point of adhesion, and suffered constriction between the portion tied down and the root of the mesentery. Three feet four inches of intestine were thus involved; and the whole length was contracted to the size of a foetal intestine. At the termination of this length, the strangulated portion itself became the strangulating agent, by being tied down by lymph to the same portion of intestine which had first adhered; and it enclosed a knuckle of four inches belonging to the portion which caused the first obstruction, and not half an inch from the adherent point. So that all this length of nearly four feet of intestine formed a small mass, tied by two bands of adhesion, consisting of two loops—a large and a small one. The intestine around the constriction was covered with tolerable firm lymph. It was of a deep red colour up to the point where it was constricted; beyond this point it was pale.

Obstruction of the Cardiac Orifice of the Stomach by a Cancerous Tumour.—By DR. FLETCHER.

William Tarplies, married, aged 56 years, in the last degree of emaciation, was admitted, under my care, into the General Hospital, March 3, 1852. He states, that about eighteen months since (up to which time he had enjoyed uninterrupted good health) he had a violent attack of influenza, accompanied by a constant burning and aching pain in the epigastrium, not diffused, but limited to a circle of about three inches in diameter, which continued for about eight months, and during that time he had frequent attacks of vomiting whilst

taking his meals. For these symptoms several blisters and mustard plasters were applied, which afforded him temporary relief. For the last ten months his stomach has been in an exceedingly irritable state, and rejected almost all the food immediately on being taken; and he has also had frequent attacks of vomiting of a clear, shiny, or frothy matter, occasionally tinged with blood, which was brought on by attempts to swallow, and sometimes even by any movement of the body. Occasionally the food was retained for one or two days, but produced much inconvenience of the epigastrium, and was succeeded by excessive vomiting, apparently of all the accumulated food.

His description accords very closely with the symptoms of disease he now labours under. As a general rule he vomits any quantity of food immediately it is taken, which appears to him to be stopped just at the bottom of the chest, and, when it is retained longer, vomiting of larger quantities of food invariably follows. Emaciation is extreme. There is no evidence of disease of the head, chest, or any tumour in the abdominal cavity, which was remarkably flattened, as if the stomach and intestines were completely empty. After having carefully examined for any evidence of an aneurismal tumour which might press upon and obstruct the oesophagus, and none being found, a bougie was passed down the oesophagus to the stomach with great care, but there it encountered some obstacle, and on withdrawing it the end was found covered with blood and pus, with which also the vomited matters were tinged for some days afterwards; but the patient experienced relief in swallowing food. From this it appeared most probable that there was a stricture at the cardiac orifice of the stomach, which was put down as the diagnosis. Food of a nutritious and farinaceous quality was ordered to be taken by teaspoonfuls at a time, (and in this way he was more successful in retaining it,) and injections of strong beef-tea. From this plan he seemed for a time to derive benefit, but at length gradually sank lower, and a slight bronchitis was sufficient to terminate the scene. He died on the 25th of March.

Post-mortem examination twenty hours after death.

—Body excessively emaciated.—*Head*: Brain not examined.—*Chest*: Heart small, not above two-thirds of its normal size, totally void of all fat, and presented a very varicose state of the veins all over its surface. The left lung was much engorged, and slightly consolidated at its lower part. The right lung was very emphysematous. The oesophagus was examined and found healthy in its whole extent; it was neither contracted nor dilated until its termination in the cardiac orifice of the stomach.—*Abdomen*: Around the cardiac orifice of the stomach (which was very much contracted equally in every way, so as to be like a stomach in miniature,) was found a firm indurated mass about the size of a small orange, by which this aperture was contracted so as just to allow a swan quill to pass through it; the end of the finger required force to be passed into it. On examination of the texture of this tumour under the microscope cancer-cells were observed. The

mucous membrane of the stomach and the pylorus were perfectly healthy. The muscular structure was very distinct; the intestines were healthy; the liver was much engorged, and presented the nutmeg appearance; the gall-bladder was not enlarged, but full of bile; the spleen and pancreas were healthy; the kidneys and urinary organs were perfectly healthy. The whole of the body appeared entirely free from fatty matter.

Correspondence.

ON BENEVOLENT AND PROVIDENT SOCIETIES.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—There is no truer proverb than that—"What is out of sight is out of mind;" and for this reason the "Medical Benevolent Fund" will require to be frequently brought under the renewed contemplation of the profession. But there are other motives which induce me to claim a corner in your valuable journal. Since I last addressed you, the "British Medical Fund" has become extinct; and the Medical Benevolent College has made rapid advances towards its zenith; and the local provident societies have had renewed and increased activity engrafted upon them; the Medical Benevolent Fund has proceeded *pari passu*, though not at the same rate of ostentatious speed, and its annuity fund has been gradually developing; and, moreover, so great a confusion has been created in men's minds, and so great a confounding of the new and more ambitious Benevolent College with the older, more humble, and more immediately useful Benevolent Fund, that for any of these motives, and more especially from a combination of the whole, it becomes necessary to review them *in extenso*, to trace them back to the principles upon which they are established, and to develop their pretensions to public regard and support. My predilections are well known, and my honorary office in connexion with the Benevolent Fund leads me of course more particularly to support that fund. But I wish on the present occasion to drop the character of the advocate, and dispassionately to review the whole system of medical charities and would-be benevolent funds, in order that each person may choose for himself to support that institution which is fraught with the greatest advantages to his brethren, unless, indeed (which is far better), he can support them all. And then, to such as possess ample purses and a truly Catholic heart, I would most cheerfully appeal to every good principle of their nature, and I would say, *support them all*; embrace all their respective objects within the reach of your expansive bosom; and by personal sacrifices of cash, time, talent, and influence, do all that you can to ameliorate the sufferings and the sorrows of the large professional family. Turn not a deaf ear to the application of him

who is ready to perish, but earnestly seek that blessing which sacred misery alone can confer—even the blessing of him who has nothing else to give than the pure offering of a thankful heart.

It might be almost superfluous to waste a paragraph upon the extinct "British Medical Fund;" at all events I would adhere to the adage, "*De mortuis nil nisi bonum*." As a provident fund it promised well, and was entitled to support; and while, in common with many others, I can but lament the sums which were expended upon its presumed establishment, yet I lament still more deeply the apathy which allowed it to sink hopelessly to its grave, without leaving a trace behind it, except the regrets of a few of its friends, and especially of those who watched the loss of its sickness fund with deepest sorrow—a sorrow unmitigated by the hope of seeing a similar fund engrafted upon some other institution.

It has been often asked,—“Why not engraft it upon the already existing Benevolent Fund? There are several reasons against such an amalgamation. And first, with reference to its principles: a sickness fund must of necessity be a self-supporting, or provident fund, while the Benevolent Fund is purely charitable. A sickness fund can only be supported by the combination of a large number in the one object, of the *many healthy* relieving the necessities of the few sick—the general principle upon which all our benefit clubs are founded. But the history of these clubs leads to the conclusion, that in this matter their calculations are unsound, for unless largely supported by honorary members, they generally fail, and come to nothing after a few years, when the influence of age gives to the once young and flourishing society a character of feebleness and dependence, which assuredly conducts it to extinction.

In professional life the sickness fund has been found most difficult to manage among the clergy; and it has become necessary, while faith has been kept with original subscribers, to adopt new and more stringent regulations for their present guidance. In fact, unless these can be disenthralled from the prevailing spirit of selfishness, it is obviously impossible to protect such an institution from the encroachments of the valetudinarian, the hypochondriac, the nervous, and the slight—though the habitual sufferer. Far be it from me to underrate the sufferings of this class of individuals, and to themselves, I doubt not, they are great sufferers; but the nature of their sufferings renders them excrescences of morbid growth upon the social body, and only to be removed by extirpation. But this involves the elements of the *stability* of such institutions, and leads their friends and well-wishers to a state of doubt and hesitation most painful to themselves, and most fatal to the success of their good wishes. If such an institution should ever be established, its success in perpetuity can only be insured by much larger sacrifices in health, or by much smaller support to the sick members, during sickness. But then, as has been shown in the example of the British Medical Fund, in the *present* state of the minds of men, with regard to these provident sacrifices, such

sacrifices will not be made, and I confess it does appear to me, that till men have become wiser and better, the establishment of a successful and enduring sickness-fund is utopian.

It will, perhaps, be asked,—How comes it that certain provident societies have flourished, as for instance,—the Widows' and Orphans' Fund in London, the Kent Medical Benevolent Society, the Surrey, the Eastern Counties, the West Riding, the Midland Counties, the West of England, and several others? The reason is obvious. First, they have been treated as benevolent funds, and many a charitably-disposed individual has become an honorary member, and thus large funds have been accumulated, because the honorary members had no chance of becoming claimants upon the fund; while in the class of probably future claimants, a very large proportion would not deprive themselves of the pittance required for *membership*, and without this membership they could have no claim for relief. The provident *few*, therefore, would obtain relief from ampler funds accumulated by the benevolence of the charitable, and thus these institutions would do much good in their limited sphere. But why should we turn our back upon those who have not been thus provident?

Let us discuss this question for a moment. We can have no doubt of the prudence and forethought of provident and prudential societies. But are the improvident to be wholly blamed? At least suspend your judgment before you condemn them. Look at the history of a young man entering into life, with all the hopefulness of youth,—with energies unbroken,—with hopes unblighted,—with zeal and ardour unchilled, and with the glowing future surrounded by a halo of joyousness and success,—with a fixed determination to devote his life to his profession, and with a full anticipation that that profession will give him, as it justly ought to do, the means of gentlemanlike existence. At this time, probably, his little capital has been expended upon his education, and he has no capital to fall back upon, either to purchase a partnership, or to support himself for a few years, while he is making a practice by his own talents and industry, amidst all the keen competition of an over-crowded profession. He does not at this time insure his life, because every farthing he can scratch together is absorbed by the daily demands of life, and the necessity for keeping a horse, and making a respectable appearance, without which he has *no chance of success*. He is now told by some of his friends, that a medical man, if he hopes to succeed in practice, must have a *wife*; and he begins to look about him for such a companion—such a sharer of his cares and anxieties—such a solace in all his toils—such a participator in his joys and sorrows. It is not very likely that a man, without capital, and without large practice, should be able to engage the affections of a lady who has property of her own; consequently, it too frequently happens, that his choice is made from the well-educated, ladylike, but penniless class of governesses; and though he envisages the fact, that his future wife has no money, yet in his sanguine

hopes for a successful futurity, he persuades himself that he shall be able, by a little increased industry, and energy, and prudent expenditure, to support a wife, which, in the meantime, he has succeeded in convincing himself is indispensable to his success. He marries, but finds that he is less visited than he expected, and that the accession of patients is very slow work; and that, although he gets on, it is chiefly amongst the poor,—amongst those who either *cannot*, or *will not* pay; and still he finds at the end of the year that his Christmas bills are large, and his receipts are small, and that he has great difficulty in making both ends meet—perhaps is a *little in debt*; still he hopes for improvement, though he is so hard up for ready cash that at this time he hesitates the outlay which is necessary to constitute membership in a provident benevolent fund. It would have been entirely right for him to have thus enrolled himself before he married; but can we visit him with severe censure, when the glowing heart, as yet unchilled by the selfishness of the world, has led him astray from the sober judgment of a cooler and more calculating policy, and when we look to the difficulties with which he has to struggle. True! he need not have married; but, in addition to his inclination leading him that way, he has the conviction of his own mind, and the recorded belief of his friends, that he will not succeed, unless he do marry: and it is the fact, that if he remained a single man he would have far greater difficulties in his way.

At the end of his first year of marriage, he probably has an addition to his family, and with it an increased and unavoidable *expenditure*; and this is a sufficient excuse to his own mind for not belonging to the Local Benevolent Fund as it is called. This, then, is adjourned as a thing to be done, when circumstances enable him to do so, and when he is rich enough to spare the necessary annual premium; and a sufficient excuse is presented to his own mind in the belief, that the tiny stranger will add very little to his expenses, and that, as soon as he is able to do so, he will insure his own life, the delay adding a *very little* to the premium, and therefore adding to the annual burden a scarcely appreciable weight. But, alas! who can reckon upon futurity? Year after year rolls on, and probably each year adds another to the first little one, and expenses increase faster than the income is augmented, the amount of unliquidated Christmas bills becomes heavier, and each year at its termination finds the life uninsured, and the power of insurance lessened, and the future yet gloomier. But still the buoyancy of youthful hope is encouraged by occasional success; and the flattering tale is repeated, that in another year or two the income will be better, and the insurance premium will be spared. In some instances it is so, and a provision is made in the shape of annuity for a widow, or an endowment for children, or a provision for old age; but not so in the *majority of cases*. And now comes the opposite side of the picture. Families increase;—income is not enlarged—perhaps it is diminished by competition;—the partner of his cares and sorrows falls into bad health, overburdened with the

anxieties of life;—children must be educated, and the approach of want is beginning to be felt, or at least the pressure of an income so straitened, that he is never free from care and apprehension; his creditors grow weary,—he is summoned to the County Court,—he is harassed at every turn; the selfishness of patients,—the obduracy of Poor-law Guardians,—the misery of perpetual duns,—the consciousness of the injustice he is perpetrating to his own family, and his creditors,—and the impossibility of making provision for the future by life-insurance, all press upon his physical resources; his temper is soured; he becomes morose, captious, irritable; he is driven almost to distraction,—the weak organ of the body gives way, and now his own sickness is superadded to his family troubles; he can no longer insure his own life, even if he had the means, and presently his energies are quenched in the darkness of insanity: there is no longer any income, and his family has to support him in an asylum, they themselves being penniless, or objects of commiseration to some purely charitable, and simply benevolent institution. Now, Mr. Editor, this picture is not imaginary, *it is drawn from life*, and is one of those cases which is only to be met by our *own Benevolent Fund*.

Again, supposing the integrity of the mental organ is not impaired *as such*, still the same result of incapacity for practice is often produced by *paralysis*, or by the whole train of dyspeptic symptoms, ending in ulceration of the stomach, or disease of the liver, or of some other of the chylopoietic viscera. Or, in all the vicissitudes to which he may be exposed, the latent seeds of consumption may have been developed, or the cruel ravages of typhus or cholera, or any of the *mille mala* to which our frail nature is amenable, may be as surely the means of conveying him to his long home before provision has been made for his family; the widow and children are left young, and in their emergency again dependent upon the Benevolent Fund as their only harbour of refuge in the day of their calamity. Or a thousand maladies may assail the wife, and the young widower is left without any one to share his sorrows, with a young family, and now in difficulties, and with a yearly increasing debt, and, moreover, with a yearly prospect of increase, for his affectionate and trustworthy housekeeper is gone, and his expenses are increased, while the means of meeting them are diminished—a series of evils which is only to be mitigated by a fund from which temporary relief may be obtained. It is easy to say that all these evils might have been provided against, but in all these difficulties it is not easy to accomplish it; and the hope of its being more easy another year, and yet another, leads him on with the bright vision of future hope, till it is finally quenched in the night of despair. If, in any of these cases, application for relief is made to either of the *quasi-benevolent* local funds, the reply is, we can only relieve our *members*.

Pardon me, Mr. Editor, if I venture to express my apprehension that the simple fact of the Benevolent Fund being an integral portion of our Association is

forgotten by many of your readers; and I take this opportunity of reminding every member of our noble Society, that when he joins our Association he *voluntarily* incurs the obligation to contribute towards the support of *its* Benevolent Fund. It has often been proposed to make this obligation compulsory—a proposition which I have always resisted, because there is neither charity nor benevolence in paying a tax; and our Benevolent Fund is essentially *charitable*, and therefore opposed in its principle to every compulsory obligation. But this does not diminish the obligation alluded to, it rather adds to its weight, because it appeals to the generosity and justice of a so-called charitable profession, and calls into its aid, all the higher sanctions of *religious principle*. I should not have adverted in this place to this indefeasible duty, had I not been struck with the fact, that the *usual prominence* was not given to the Benevolent Fund at Oxford; and that in your report of the late meeting of the South Wales Branch, at Swansea, it does not appear to have been alluded to at all, and I am afraid to say how few of the seventy-five new members recently enrolled in that district are subscribers to the Benevolent Fund. This is the more extraordinary, when the President, in his address, claims for our profession, that in no other, “is the ear of pity and compassion more open to the tale of woe, oppression, and distress;” and that the motto of our Society may consist in the two scriptural quotations:—“Let brotherly love continue;” and “this commandment I give to you, that ye love one another.” I repeat, Mr. Editor, that in such an address, and at such a meeting, it does appear to me extraordinary, that no mention is made of our Benevolent Fund, nor of the absolute duty of contributing to its support. Believing the omission to be wholly unintentional, I fulfil my own duty, as Treasurer, in making known to each member the obligation he has incurred, in the full expectation that the South Wales Branch of our Association, will at least emulate her northern elder sister, in her deeds of charity, and her acts of duty.

Forgive me this digression. And now, Mr. Editor, though I have palliated the conduct of those who have not provided for their families, I am not *defending* it; and with regard to this provision, there are comparatively few among those even, who are struggling for their existence, who do really think about it. This is sufficiently proved by the fact of the few who insure their own lives;—of the comparatively very few who belong to the local funds, and of the still fewer, who came forward to support the British Medical Fund, with all its claims upon their sympathies. Now, it really is an unquestioned moral duty to support some of these objects; and as the British Medical Fund has died from inanition, it becomes a more sacred duty to attach oneself to one of the *local funds*. But it will be said, and said with truth, that the great majority of the members of these funds consist of persons who are well off in the world, and who have no prospect of ever being chargeable to its resources. So much the better for it; for if the same proportion were in an opposite

direction, the fund would soon fail, from the demand upon its resources, and the members would then be left with a very scanty pittance. *Now*, they may accumulate; but then, they would be ruined, and the only inexhaustible charitable fund will be found to be the *Medical Benevolent Fund, not the Medical Benevolent College*. The introduction of this term in this place, leads me to add a few brief words on this latter scheme; and I would wish to speak of it with all imaginable kindness, and with unbounded respect and admiration for its chief supporter, Mr. Propert. Mr. Propert has accomplished what I believe no other man could have done: his own views are truly benevolent; and by the agency which he has employed, he has accumulated a large sum of money. But I would venture to say, though large, it is very inadequate for the great purpose he proposes to effect. Of the constitution of the College, I wish to say nothing, but simply to express my fears, grounded upon the facts of past history, that it is *impossible* to keep it free from the disturbing agencies, which in other places and professions, have thrown the blight of discord upon the best conceived views, and introduced elements of distraction within the College precincts. To carry out the design fully, an enormous outlay will be at first required, and a princely reserve must be saved for a permanent source of income. Without this the best conceived plans must fail; and in order to give the College a hope of carrying out its designs, it must not be left with a debt upon its shoulders, nor dependent upon the precarious support of annual subscriptions. True, it will have the advantage of possessing a locality—*visible and tangible*, the visible will be there when its walls are reared, in the beautiful scenery of Epsom; the tangible is only to be obtained in its educational boons, or in its asylum for widows or decayed medical men, by the possession of a certain amount of income, and certain means of defraying the expenses of a canvass. And, after all, I cannot but think, that this same expenditure, about to be invested in bricks and mortar, would produce an infinitely greater amount of good, if invested in consols, and the income therefrom derived were applied to granting annuities, and the aged males or females (after the example of the Benevolent Fund,) were permitted to enjoy these annuities at their own homes, surrounded by their own little comforts, tended by the kindness of families, and placed at home—the only situation for the *real development of so much of the charities of home—the sympathies of relative kindness, and the affections of a family.*

[To be continued.]

LETTER FROM W. A. COX, ESQ., ON THE CASE—"BOURNE v. COX."

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I herewith send you a fuller and more correct report of the County Court case commented on by you in your last number, and most readily answer your call for an explanation.

The circumstances I will relate as briefly as possible. On the 16th of last June I was consulted by a patient, who gave the following account of himself:—About two months before he had contracted gonorrhoea, for which he had from that time been under a druggist; and about a week ago he had had suspicious intercourse, from which he feared had arisen fresh symptoms of disease.

On examination, I found he had gonorrhoea with stricture of the urethra, an ulcer which I believed to be syphilitic, with an eruption on the margin of the prepuce, which was indurated, and in a state of phimosis. He had also an inflamed gland on Poupert's ligament on the right side. He appealed to me to cure him as quickly as possible, as he was about to go abroad. I put him under a mild mercurial course, advised him to foment and poultice the bubo, and recommended the passing a bougie medicated with copaiba night and morning; a practice which I have found very efficacious in old-standing gonorrhoea. On his representing to me the impossibility of making the necessary applications at his own home without detection by his mother, I, in consideration of the urgency of the case, permitted him to attend at mine, where I made the necessary applications myself. These attendances occupied generally half an hour, sometimes longer. And in addition to these attendances, so anxious was he about his case, that he was at my house sometimes three, sometimes four times a day. This treatment was continued till the 24th of July, when he applied during my absence, had his last bottle of medicine, and left, stating that he was much better, and would call on the following Saturday for his bill, which he requested I would make out.

It may be as well that I here state, that about the 4th of July my patient showed me a bottle of medicine he had got from Mr. Field, the usual medical attendant of the family, whom his mother had called in, seeing her son was out of health; and asked me if it would interfere with my medicines. I at once, feeling the awkwardness of two medical men being in attendance, and yet not acting together, urged him to confide in Mr. Field, and let him go on with his venereal disease. To this he strongly objected, fearing Mr. Field would make his state known to his mother; and finding I could not overcome his scruples, I consented to continue attending him.

He was then attended by me, with no ordinary sacrifice of time and trouble. He was virtually cured, as Mr. Harries's evidence showed, who saw him immediately after he ceased attending on me. And mark the return he makes me. I neither see nor hear of him till I am informed casually on the 6th of August, that he was about to sail the following day for Australia. I then, giving him to the last moment to call on me, went to his house between seven and eight o'clock in the evening, and there had the information confirmed that he had left Bath, and was to sail from Bristol the following day, at twelve o'clock. I came home and made out my bill in my ledger, and in so doing I felt that I was justified in making the full charges that I conceived the law would allow me. I considered the time, the trouble, and the unusual nature of the services rendered, and rendered at his request; and I did not think that

half-a-guinea, under the circumstances of the case, was more than I was justified in charging him. This brought his bill to £21. 5s.; and by the advice of Mr. Slack, a most respectable attorney, I arrested him for this amount. I had reason to know that he was a young man of property; but he pleaded poverty, and I consented to take £15, and give him his discharge. He then returns to Bath, trumps up a story, which, on the trial was proved to be false, that I had sent him in a bill for £2. 6s.; and his friends commence an action in the County Court for malicious arrest, laying the damages at £50. Not content to await the trial, the public-houses all over the city are made use of to circulate the grossest calumnies, and thus a strong feeling is excited against me. Confident in the justice of my own case, although I heard six medical men were to be brought forward by the plaintiff, yet, as I flattered myself that I stood pretty well with the profession, being conscious that I had never done a dishonourable action towards any one of them, I relied on their honour and integrity, and did not provide myself with a single medical testimony on my behalf. I was generously offered support (not by those who gave evidence in my favour on the trial, but by a gentleman of as high respectability and as long standing as any in the profession in this city), but I refused to allow another to share in the prejudice that had been raised. The trial came on, and then to my utter astonishment I found the medical witnesses deposing to the impossibility of the existence of such a complication of diseases as that for which I had made out a bill, and which I subsequently swore had existed in this case. Fortunately for me there were two gentlemen in court, Messrs. Bush and John Barrett, who had the manliness and generosity to stand forward when they saw an attempt made to crush a professional brother, and voluntarily gave evidence on their own experience that they had seen similar cases. I here beg publicly to thank them; and I tell them that I appreciate their conduct the more highly because it arose from the spontaneous and unsolicited impulse of generous, manly, and independent feeling.

But can I wonder at the verdict that was returned after the medical evidence for the plaintiff, that evidence being, as the Judge charged the Jury, "*that they all agreed that they did not believe that the diseases which were specified on the face of the bill, ever could coexist in the same patient.*" (See *Bath and Cheltenham Gazette*, September 8th, 1852.) Observe, the adverse medical evidence denied the possibility of the coexistence of gonorrhœa and syphilis. With such evidence as this before them, the Jury could come to no other conclusion than that the bill was a concoction, and the whole transaction a fraud. My only wonder is, that with such extraordinary medical evidence against me, the Jury were bold enough to cut down the damages from £50 to £15.

With regard to the bill, portions of which you have quoted, I must throw the responsibility of the form of it on my attorney, by whose direction it was drawn up and delivered to the plaintiff's attorney, on their application, after the action was commenced.

In explanation of no bill having been delivered previous to the arrest, the simple answer is, that the

patient never afforded me an opportunity of so doing, and I could not send it to his home without risking discovery by his mother of that secret he was so anxious to keep from her.

There is another circumstance I must allude to, It is, as to the interlineation of the operations. This arose, as I explained on the trial, from the fact of the operations having been performed after the medicines had been ordered in the day-book, and I pointed out to the Judge and Jury many similar entries in the same book to other patients. Mr. John Barrett has since closely examined my day-book, and has publicly declared, in a letter to the *Bath Journal*, that "the internal evidence of the whole book supports Mr. Cox's statement as to the manner in which those entries were made." I have through him invited, and I here repeat the invitation, of an examination of my day-book to any member of the profession whose mind may not be satisfied on this point.

This, Sir, is my case, as it stood after the trial, and here I should have been contented to leave it for the public to judge of it, with confidence that they would, on cool reflection, put a proper estimate of my conduct in this transaction, that they would remember it was no feature in my conduct to overcharge, overdose, or defraud; and that they would see I had been led into what might be considered extreme measures in order to prevent a dishonest and unprincipled man defrauding me of my due.

But as it appears you make the chief point in the case to be the large quantity of medicine sent in, which, you say, gives a handle to the homœopath, let us see what this large quantity amounts to. Just one six-ounce bottle and one powder per day. If this be an offence against legitimate practice, I much fear I sin in this respect in company with the greater portion of my medical brethren, and I must cry peccavi, and endure any reproach I may have incurred thereby.

But, Sir, I have done. I have laid my case before the profession, and I neither fear what their verdict will be on my conduct, nor do I fear what will be the ultimate verdict of the public.

I am, Sir, your obedient Servant,
W. A. COX.

Foreign Department.

GERMANY.

MATERIA MEDICA AND THERAPEUTICS.

ON THE ACTION AND ON THE METHOD OF PREPARING CATHARTIN.

Trenkler prepares cathartin from the unripe green berries of *rhamnus cathartica*. It resembles pure aloethin, both in a chemical and in a therapeutical point of view. One or two grains of cathartin in the form of pills usually produce one or two, or in a susceptible patient, three or four pulpy stools, without griping. Three grains form a large dose. If the first dose should fail to produce the desired

effect, a second may be given in three or four hours. Dr. Graff (of Darmstadt), who has carefully studied its therapeutic action, employs it in torpor of the bowels, in hepatic and splenic congestions, hæmorrhoids, dropsy, and gout.

By simply treating the inspissated juice of the unripe berries with alcohol and æther we may obtain an impure cathartin in considerable quantity (oz. viij. from 12lbs.), which acts very powerfully, and much like aloes.—*Jahrb. f. pr. Pharm., Jan., 1852.*

ON THE ACTION OF TRISNITRATE OF BISMUTH.

Dr. Lussana has been recently experimenting with this substance. In opposition to the views of Monneret, who published a memoir on it a few years ago, in which he maintains that it merely exerts a local and no general influence, and that it acts as a sedative on the intestinal mucous membrane, Lussana asserts that it certainly has a general action, and that it is absorbed into the system.

The following are the results of his experience of large doses in diarrhoea tuberculosa, in the diarrhoea accompanying chronic enteritis, in inveterate gastralgia, and in mesenteritis. It excites no irritation of the intestinal mucous membrane; it cannot check tuberculous and mesenteric diarrhoea. The fæces were of a brownish-black colour from the formation of sulphuret of bismuth in the intestine. A portion of the dose, varying with the amount of acid in the stomach and intestines, was dissolved and absorbed, but any of the dissolved portion on meeting with an excess of alkaline chlorides in the intestine, was again precipitated. For this reason it never appears in the urine, being precipitated by the alkaline chlorides in the blood-serum. Its passage into the blood gives rise to colliquative and scorbutic phenomena.

To avoid this noxious general action, and at the same time to avail ourselves of the mechanical and local healing power of this medicine, we should previously give some antacid, as, for instance, magnesia usta, which would chemically prevent its solution and assimilation.—*Lussana in Gazz. Med. Ital. Lombardia, 4, 1852.*

ATROPINE IN HYDROPHOBIA.

Atropine has been recently tried by Dr. Richiedei in a case of hydrophobia; but, as in the case of all other remedies, without success.

A boy, aged ten years, was, on the 22nd of April, bitten in the left corner of the upper lip by a mad dog. The wound, trifling in appearance, was cauterised about three hours after the accident, and a perfect cicatrix rapidly formed. On the 18th of May, however, the child presented certain suspicious symptoms, for which he was admitted into the hospital. His voice was suppressed and melancholy; the face flushed; eyes constantly in motion, and unnaturally bright; there was difficulty in swallowing, and convulsive motions when drink, and afterwards even when food, was offered to him. These symptoms could leave no doubt regarding the nature of the disease, although there was no furious delirium.

One grain of atropine was dissolved in a little spirit, and made into twenty pills with sufficient bread. One pill was to be administered every three hours. After three pills had been taken, no more could be swallowed. An ointment of two grains of atropine in half an ounce of lard was then rubbed into the neck, and applied endermically to a vesicated spot on the epigastrium. The boy died on the 20th of May, with slight spasms and delirium.

The only symptom which could be distinctly referred to the atropine was extreme dilatation of the pupils.—*Ibid.*

CHEMISTRY.

BILIARY CONCRETIONS.

Biliary concretions must be ranked amongst the morbid products of the secretion of the liver. Few points in pathological chemistry, in the early periods of that science, have received so much attention as gall-stones; but all the very numerous observations which have been made regarding them are reducible to the following facts:—These concretions occur principally in the gall-bladder, more rarely in the biliary ducts; in women more frequently than in men, and especially in aged persons; they often consist with cancer of the liver or of other organs, but it cannot be positively affirmed that carcinoma is a predisposing cause of gall-stones, since both these adventitious products specially pertain to advanced age and to the female sex; each is, however, often found independently of the other. Gall-stones appear to be of more common occurrence in England, Hanover, and Hungary, than in other countries. Most gall-stones are so rich in cholesterin, that the other constituents are of very secondary importance; all, however, contain one or more nuclei, consisting of traces of mucus and earthy phosphates, but principally of an insoluble combination of lime with bile pigment: a large number of gall-stones are formed of a mixture of cholesterin and pigment-lime; the latter is sometimes uniformly distributed through the concretion, in other cases we observe alternating layers of cholesterin and the brown pigment, and in others again we find only a little cholesterin in the dark brown mass of pigment-lime.

There is a third kind of concretion which is comparatively rare, namely, the black or dark green variety; this contains another modification of the pigment, which however, in this case, also is combined with lime: this variety is usually free from, or at all events very poor in, cholesterin.

Biliary concretions, in which carbonate and phosphate of lime are the principal ingredients, are very rare. (Bailly and Henry, Steinberg.)

It is singular that uric acid has occasionally been found in gall-stones. (Stöckhard, Marchand.)

All gall-stones imbibe a little bile, which may be readily abstracted from the pulverised concretion with water or cold alcohol.

The forms of gall-stones are extremely varied; while some are very regular and symmetrical, others assume the most unaccountable shapes.

Bramson has undoubtedly indicated an important point in relation to the formation of the majority of

gall-stones—namely, that it depends on the separation of a compound of pigment with lime.

Although Bramson's view had been much contested, we can undoubtedly recognise the presence of a compound of pigment with lime in the residue of the nuclei, both of cholesterin-concretions and of the brown gall-stones after extraction with alcohol and water, although we are, as yet, unable to establish a definite proportion between the pigment and the base. Every residue which is rich in pigment always contains a greater or lesser quantity of earthy phosphates and a little mucus; these earthy phosphates, most probably originate from the mucus, which, however, like the Protein bodies in the formation of phlebolites, gradually dissolves and disappears; for the phosphates never stand in a constant ratio to the mucus remaining in the concretion; the mucus may also contain a little lime, which on incineration is converted into carbonate and sulphate; moreover, we sometimes meet with oxalate of lime, although only in very small quantity; I have never found carbonate of lime preformed in the brown residue of gall-stones (if present, it may be very readily detected by observing, under the microscope, the effect produced by a little acid on the substance previously moistened with water and freed from all air-bubbles). Sulphate of lime does not exist preformed, or at all events it is only present in very small quantity.

The ratio of the ash to the organic substance in the insoluble portion of gall-stones is altogether variable; in the insoluble part of six different concretions, there were 8.5, 12.1, 16.6, 30.4, 46.3, 50.6, and even 54.70 of ash; in the analyses of these six ashes there was comparatively much carbonate and little phosphate of lime according to the smallness of the ash; that is to say, in proportion as organic substance preponderated in the insoluble residue of a concretion, so much the more was the phosphate of lime encroached upon by the carbonate. In the ash which amounted to 8.5, there were 7.994 parts of carbonate of lime, and only 0.492 of earthy phosphates; while in the ash which amounted to 54.7, there were only 12.135 parts of carbonate of lime, a portion of which originated from oxalate of lime, which was recognized on the fresh object. Bramson has pointed out that dilute acetic acid extracts lime from the insoluble residue of biliary concretions; as this lime cannot be combined with sulphuric or oxalic acid, and as only an extremely minute quantity can be associated with phosphoric acid, it must be obtained from a combination with an organic substance: and as there is too little mucus present for us to ascribe it to that course, it must necessarily have existed in combination with the pigment.

Further, if the bile-pigment were not in combination with some substance, it would be soluble in alcohol, for it is by no means a modified pigment which has become insoluble through some molecular change, but actual cholepyrrhin, in combination however with lime; and if we remove the lime by the application of a dilute acid, we obtain the cholepyrrhin, which is then soluble in alcohol, and possesses all the properties which we formerly enumerated.

An enormous deal has been written on the formation of the different varieties of biliary calculi, as well as regarding the proximate cause of the deposition of solid particles, and especially of the cholesterin; but any

analyses of the various hypotheses that have been brought forward in relation to these points, would be here altogether out of place. The following is all that is actually known regarding the mode of formation of the concretions. Mucus and epithelium generally yield the points or foci around which a deposition of solid particles occurs; we always find pigment-lime with a little mucus in the centre of the concretion, and hence we may fairly conclude that it plays a part in their formation; but the separation of cholesterin from the bile is still not explained, even though mucus and pigment-lime can and must act as solid points. The question suggests itself, whether the bile lying amongst the gall-stones is normal in its character: it has been believed that it presents nothing abnormal, but no conclusions can be drawn from any analyses of human bile that have yet been instituted, for the quantity of bile obtained from a dead body is too small to admit of an accurate analysis; moreover, the constitution of the bile when obtained after death, is generally more dependent on the morbid process which gave rise to the fatal termination, than on that which led to the formation of biliary concretions. It is, however, more than probable that, in order that concretions of cholesterin should be formed, the bile should contain a smaller amount of the solvent for this substance than the normal fluid contains; but, as has been already mentioned, we very rarely meet with bile in which there is a separation of minute tablets of cholesterin, although they often occur in other fluids, as, for instance, dropsical effusions, &c., hence the presence of solid insoluble particles must be regarded as exercising a considerable influence on the formation of gall-stones. If we inquire what it is which holds the cholesterin and the pigment-lime in solution in normal bile, direct experiments afford an answer to the question, and show that both these substances are principally held in solution by taurocholic acid or taurocholate of soda. If we digest the insoluble residue of a brown gall-stone with taurocholic acid or acid taurocholate of soda, it is entirely dissolved, with the exception of a few greyish-white flocculi, and the previously colourless solution assumes the tint of fresh bile. Strecker showed long ago that cholesterin was soluble in solution of taurocholic acid and its salts. Glycocholic and cholic (Strecker's cholalic) acids possess this property in a far less degree. The question regarding the formation of gall-stones would be very readily answered, if it could be proved that bile, which has a tendency to form concretions, was either poor in taurocholic acid in relation to cholesterin and pigment-lime, or that its taurocholic acid was decomposed in the gall-bladder, and had thus lost its power of dissolving these two substances.

Since concretions, which are rich in cholesterine, are never entirely devoid of pigment-lime, while, on the other hand, calculi, which are poor in cholesterin, are always very rich in pigment-lime, the idea suggests itself that this latter compound takes an active part in the primary formation of these concretions; indeed, the frequency of their occurrence in certain districts, in which the water abounds in calcareous salts, and in old age, when, as is well known, there is an increased tendency to calcareous deposits, and the separation of cholesterin is promoted by the attenuation of the animal fluids.—*Lehmann's Physiological Chemistry.*

Reviews.

Lectures on the Principles and Practice of Midwifery.

By E. W. MURPHY, A.M., M.D., Professor of Midwifery at University College, London. Taylor, Walton, and Maberly, 1852. 8vo, pp. 616.

IN the preface to the above work, Dr. Murphy remarks that it is his wish to convey to the reader a comprehensive view of the principles and practice of midwifery, and that he has found it necessary to publish it, because it is no easy matter to advise the student in the selection of a work to guide him in its studies, in consequence of the different opinions held relative to the use of instruments, the management of placenta prævia, the employment of ætherisation in midwifery, and the treatment of puerperal fever. From this statement we naturally expected a general treatise on all the subjects usually comprised under the head of midwifery, and that the student might rest satisfied with the information to be found therein. In this, however, we were disappointed; and we think it right to caution our readers, that they will find little besides the four divisions enumerated above, with the exception of a very good description of the anatomy of the bones of the pelvis, and the different modes of its measurement. But in this description Dr. Murphy has omitted altogether the anatomy of the external and internal parts of generation. The physiology of the organs of generation is also passed over, and throughout the book we do not find any reference to any of the following subjects, viz.:—menstruation, normal and abnormal; generation; utero-gestation; signs of pregnancy; duration of pregnancy; sterility; superfætation; extra-uterine pregnancy; fetal accidents; and abortion; while the whole subject of the propriety of the induction of premature labour, with the mode of performing it, is dismissed in about a page and a quarter.

But considering these lectures as treating almost solely of these four interesting subjects, we can scarcely sufficiently recommend them to our readers. With reference to the first of them—viz., the use of instruments, Dr. Murphy is strongly opposed to delay in their employment whenever it can be decided that they will eventually be required. In his remarks upon the use of the forceps, he suggests the pro-

priety of waiting only *four hours* after the arrest of the head, instead of *six*, as recommended by Denman and others. He says:—

“If there be the least indication of pain, swelling, or heat in the passages, you should not delay one moment from the time that these symptoms first present themselves, when you are satisfied that the forceps may be applied. Promptitude is the secret of success, and in nothing is it more evident than in the case we are supposing. It is possible the pains may be strong and frequent; and it is generally a safe recommendation not to interfere so long as the uterus seems to have sufficient power, but rather to wait until the pains become feeble, or the action of the uterus is suspended. Nevertheless, in the case before you you cannot act upon such a rule. If the head be arrested, if the pains be strong but insufficient, if inflammation set in, to hesitate to deliver must be considered the most mischievous vacillation. Every hour spent in these useless efforts of the uterus only increases your difficulty—only renders the operation more hazardous, and diminishes your chance of success; because the application of the forceps to parts already inflamed must contuse them, to a certain extent, and if so, the contusion will terminate in a slough.”—p. 181.

It has become so much the fashion of late years, to abuse Chamberlin and Burns for their over-recommendation of the forceps, that most of our writers on midwifery have been led into the opposite extreme, and we therefore rejoice to find Dr. Murphy advocating the happy mean between the two extremes of rash and meddling interference on the one hand, and on the other, of timid reliance upon the powers of nature. There can be no doubt, that in a *healthy female*, the forceps, applied with care, can never injure the mother, that is to say, if the pelvis is of a size to admit the passage of the head without craniotomy; nor do we believe the child runs so much risk as it would do, by being left for a longer time subject to the propelling force of the uterus. But then you require for the due performance of the operation, *mens sana in corpore sano*, that is, you want the careful weighing and comparing in the mind, of the condition of the various elements required to bring the child safely into the world unassisted by art—viz., the comparative strength of the uterus, the size of the head, and that of the pelvis; and after deciding on the use of the forceps, you ought to have an experienced and ductile pair of hands to carry out the mental decision. It is right, therefore, that all those who have the instruction of the student, should be careful in their cautions on the abuse of instruments, but nothing can justify the publication of false dogmas, for fear of the

truth leading to rashness. Let the student be cautioned against this fault as often as you please, but we protest against his being treated in the way in which old nurses mismanage children, by the relation of ghost stories to keep them out of mischief.

The eighteenth and nineteenth lectures treat of hæmorrhage, and are very interesting, and in some respects original, though not very clear, especially in the discussion of the *natural* mode of stopping the flow in placenta prævia. In this respect Dr. Murphy shows that Nature attempts to prevent inordinate hæmorrhage by detaching the placenta, and if the powers of the uterus are sufficiently great, this is effected, and the bleeding ceases. But too often the uterus is not capable of completing its work, and then you have gush after gush, accompanying every pain, till the patient becomes more and more exhausted, and unable to effect the full expulsion of the contents of the uterus. Dr. Murphy advocates the employment of turning only when the presentation has been discovered early enough to act before there has been so great a loss of blood as to endanger the mother; indeed, his leaning evidently is to the separation of the placenta in all cases, believing that the life of the child is not to be considered for a moment, when weighed against the mother's. This view is held all through the lectures, to an extent which we think scarcely justifiable. We have no right to hold the scales; but our office is to heal all, whether young or old. It would, we think, be as justifiable to destroy a patient who is attacked with an infectious disease of a dangerous character, in order to prevent his communicating it to a more valuable life, as to destroy an infant (while a chance of its living remains) in order to avoid risk to the mother.

The twentieth and twenty-first lectures are devoted to an essay on puerperal convulsions, in which the question of immediate delivery is answered in the following manner, supported by voluminous tabular reports:—

1st. That in those cases in which delivery was unaided (about half the whole number) the mortality was least. 2nd. That when the crotchet or forceps were used, the deaths were only slightly increased. 3rd. That the highest mortality was in those cases when the child had been turned.

Dr. Murphy's views on the use of chloroform are so well known that we need not allude to them here.

The remainder of the work is almost entirely occupied with a very valuable investigation of the history, symptoms, and treatment of puerperal fever, occupying nearly seventy pages. Our limits, however, will not allow us to do more than remark, that Dr. Murphy supports the generally-received view of the identity of puerperal fever with erysipelas, at least as far as the essential characters are concerned. These chapters will be read with interest by all engaged in obstetric practice. There are a few other subjects upon which Dr. Murphy has written short but extremely interesting lectures, such as rupture of the uterus, inversion of the uterus, and phlegmasia dolens; but as there is nothing in them admitting of controversy, he has not bestowed so much time and labour as upon the subjects to which we have alluded to more at length.

Provincial Medical & Surgical Journal.

WEDNESDAY, OCTOBER 13, 1852.

WE have received a communication from Mr. Cox, relative to the trial commented upon by us in our number for September 15th, which we publish at page 537, but we regret to find, that instead of an explanation of the verdict, supported by fresh facts, Mr. Cox only endeavours to refute it by the supposition that the jury were mystified by "the medical witnesses deposing to the impossibility of the existence of such a complication of diseases as that for which he had made out a bill, and which he subsequently swore had existed in this case." It may be remarked, that this opinion, was not held to the full extent by all the witnesses for the plaintiff, and was fully rebutted by Mr. BUSH and Mr. BARRETT. It was therefore not put to the jury in the charge of the Judge, at least it is not included in the report sent us by Mr. Cox, himself. This is, therefore, a discussion wholly beside the question, which turns upon the genuineness of the bill as sworn to by Mr. Cox. The treatment is a point upon which we may all have our separate opinions, but the stigma cast upon Mr. Cox is, not that he holds a wrong theory of venereal diseases, but that he, after supplying a patient with forty-two bottles of mixture, and the same number of powders in five weeks, and duly

entering them in his day-book, to the amount of £5. 10s., afterwards interlined that book with items for attendance and passing bougies, in order to make up the amount £21. 5s. And moreover, that he made an affidavit that this was a just debt, due from Bourn to him. This was very clearly put by the Judge to the jury, (which was a highly respectable one) and was characterized by him as a gross fraud, and we are sorry to be obliged to confess that we can see no way of escaping the imputation. To prevent mistake we think it advisable to print the Judge's charge *in extenso*, as given in Mr. Cox's pamphlet.

"His Honour then summed up the case very carefully. In order to be satisfied that the provisions of the Act of Parliament were complied with, the Jury must see that there was a *bonâ fide* debt of £20, and next that there was reasonable ground to believe that the plaintiff was about to quit England for the purpose of defeating or delaying his creditor. The importance of the case to the friends of the plaintiff was nothing compared with the importance of it to Mr. Cox; and he mentioned that, because the Jury would not be disposed to give a verdict against him, unless they were satisfied that there was no reasonable doubt in the case as to his having committed that which had been described as a gross fraud, one of the most disgraceful frauds, which any man in any station of society could be guilty of. They would not, therefore, convict Mr. Cox, unless they felt there was no reasonable doubt about the case. If they thought it was attended with any reasonable doubt on either side, in his favour as well as against him, then the only fair verdict which could be given would be for the defendant. [Having referred to various points in the evidence, his Honour referred to the production of the books.] The day-book was very important. If all the attendances had been regularly made, and if all of them had been as free from doubt as they were in the consecutive entries of them from day to day, showing clearly that they were made from day to day, if that had been all, the greatest degree of credit ought to be given to that book. Now, it was admitted that the entries of the operations were made after the bodies of the entries. If they were made after the entry of the medicine, on the same day, there was an end of the difficulty. But, if there were any reason for coming to the conclusion that those entries were made at a subsequent period, for the purpose of assisting the case, it was clear what the result of that must be. On the other hand he must say this, every medical gentleman was considered to have a very considerable latitude as to the amount of his charges against the patient. His own prudence and discretion with due regard to his own interest would keep him straight in this matter. Mr. Cox, in making out his bill, had a right to consider the willingness or unwillingness of the patient to pay; and, therefore, if they should consider that the bill had not been very considerably aggravated, he did not think it was enough to satisfy the right of the plaintiff to recover a verdict against Mr. Cox. But the question was whether or not it was done in point of fact for the purpose of enforcing

the arrest. If the defendant had exceeded the latitude prescribed to professional men, then their verdict must be against him. If, on the contrary, they thought that all the work done and all the medicines were truly stated in the bill, then they would have to consider whether the defendant had not made out such a defence as would entirely vindicate him from the serious charge brought against him. He (the learned Judge) confessed that the entries appeared to him to be made when the entries to which they were attached were closed, and as far as he had looked at them, they carried the impression of being made at one time. It was, however, part of the evidence, and was therefore liable to be sifted and examined by the Jury in the same way as the other evidence. The question for them was, whether Mr. Cox had fraudulently augmented the bill for the purpose of enforcing the arrest. He (the Judge) would repeat what he had said, that if there were a reasonable doubt, they would give their verdict for the defendant. It was a case which he did not feel justified in leaving with them as free from doubt. It was their business to solve the doubt, and to say whether the plaintiff or the defendant was entitled to their verdict.

"The Jury, after a consultation of ten minutes, returned a verdict for the plaintiff—Damages, £15."

From the above, it is clear that the profession, and more particularly the Provincial Medical and Surgical Association, must either support Mr. Cox as an aggrieved member of their body, or they must affirm the truth of the verdict given by the jury. The facts of the case were to have been brought before the Bath and Bristol Branch meeting of the Association, on Thursday last, and we are quite sure, though we have not heard the result, that Mr. Cox will have received that treatment from them which his case demands.

At the urgent request of Dr Roe, we publish the following letter which was sent for insertion in the *Lancet*, but refused admission. At the same time it is due to ourselves to premise, that we concur with the Editor of the *Lancet* in his strictures upon the appeal to the public made by Dr. Roe, by means of an article "On the Treatment of Ulcerations of the Cervix Uteri," appended to the report of the trial published by him. We know how difficult it is to rest contented under what we may consider unmerited censure, but it has long been decided as an article of medical ethics universally admitted, that no appeal to *the public* should ever be made by one medical practitioner who considers that his treatment has been impugned by another, and so long as all advertisements shall be repudiated, which we trust will be, as long as the profession itself exists, so long will this salutary

rule continue; for the contrary custom would at once open the door to all sorts of evasions. No sooner would a practitioner fancy himself reflected upon than he would forthwith issue a pamphlet, discussing the disease which formed the subject of the quarrel, and puffing his own treatment to an extent which we hope never to see realized.

We are therefore obliged to maintain, that it "is heterodox for a medical man to publish a report of a case, when his treatment was impugned by other medical men," if that report is intended for the public, and is followed by a treatise on the disease in question, which, in this case, we cannot but think was written in a popular style. We fully sympathise with Dr. ROE in the position in which he has been placed, and we readily undertook his defence in a former number of this journal, but we strongly recommend him to leave his case in the hands of the profession for the future. We can only say for ourselves, that had we received "the Report of the Trial" before writing our remarks, we should certainly have commented upon the "Heterodoxy" in a similar strain to that of the Editor of the *Lancet*. Indeed we are induced to hope from our correspondence with Dr. ROE, that on mature reflexion, he will consider it right to confine himself henceforth to an appeal to those only who can form an unbiassed estimate of the case before them.

To the Editor of the Lancet.

SIR,—While I offer you my best thanks for your very favourable notice of the report of my cause in last week's *Lancet*, I must be allowed, at the same time, to express my surprise at your strictures on my adding to that report a few remarks on the "Treatment of Diseases of the Womb." It was not until I saw your review that I was made aware I had laid myself open to the possibility of misconception or censure by their publication, and even now I must incline to the opinion, that your abhorrence of even the shadow of heresy in matters medical, has made you for once somewhat hypercritical—somewhat more severe than the occasion called for. Is it heterodox for a medical man to publish a report of a case where his treatment was impugned by other medical men, and the disease itself almost denied, and then for him to give authorities for his practice? This is all that I intended doing—all I believe that I have done; for in writing the book I had no motive in view other than my own full, complete, decided justification—justification not only of my truth as to the disease I was treating, but as to the propriety of that treatment.

You say the work is intended for the public, but I see no reason for that inference: it is not written in the

popular style usual when such is the case; nor is there anything in the mode of publication, at all events as far as I am concerned, I submit, that supports your opinion; for although the book is issued not from a medical publisher, but from a publisher of general literature, it was not until after I had applied to Mr. Churchill, and he had declined publishing it, (*because it was a pamphlet*), that the local publisher was given a *carte blanche* as to his proceeding, and he then appointed whom he pleased. But we will allow, for the sake of argument, that it is written solely and expressly for the public. On whom, then, should the censure rest? on the medical man who writes merely to clear himself from undeserved imputations, or on those practitioners who make certain false assertions reflecting on his treatment, which are circulated through the public press, which, therefore, require refutation, if not through the same channel, at least through one equally public and local?

It must be borne in mind, that the cause was fomented and assisted by two medical men; "in this instance," as the talented Editor of a contemporary journal remarks, "the patient's ingratitude was fanned by professional jealousy."* A woman, my patient, and owing me twenty-seven guineas, went to a Dr. Prance, who told her she had nothing the matter with her, and ultimately advised her to go to "Mr. Hunt, the lawyer." In the witness-box he (Dr. Prance) condemned the speculum, said symptoms were not deceptive in uterine diseases, asserted his strong belief that the uterus was healthy when he examined her, *that there never had been any ulcer on it*, and that his finger could detect uterine lesion if any had existed!

But Dr. Budd went further, and even still more unjustifiably asserted, that the speculum did more harm than good, and was used only by the lower grades and the indiscrete members of the profession! He not only gave his evidence, but also tried to impress his opinion on those around him, *that there never had been anything the matter with the woman*, and yet it now transpires that she had been under his care as a gratis patient not many months before she came to me, and her syphilitic symptoms then induced him to order iodide of potassium and blue pill for her! Is it not almost too monstrous for belief, that a man, by profession a gentleman, or indeed any man, should allow his petty spite and malice thus to overcome his principle?

Well, Sir, these reports were fully published in the local papers, and read by a local population among whom I practise. How, then, was the injurious impression produced by those false statements to be removed? Several methods suggested themselves. The publication of a report of the cause, with an analysis of the evidence, was the most direct mode, but one that resolved itself into an attack upon the two medical witnesses, which I desired to avoid. An article in the local papers was not, of course, to be thought of; but an essay on the complaints of the womb, where authorities were cited for the treatment I pursued was considered an objectionable course. That plan and the MS. were submitted to a first class London physician—himself the author of several works—and, *meeting with his entire and decided approval*, the "Remarks"

were dedicated as a mark of esteem to my truly excellent and talented friend, Dr. Butter, with his consent, and published.

I shall endeavour in the next edition to make them more worthy of being associated with the name of a gentleman I so much regard, and as you say they are now quite contemptible with reference to their strictly professional character." I hope they will be then found deserving of your kindly criticisms; but how the aphorisms of such men as Sir Charles Clarke, Drs. Locock, Lever, Murphy, Bennett, Tilt, &c., which constitute nine-tenths of the said "Remarks," can be contemptible, is a problem I will not pretend to solve. Be that as it may, the edition, large as it was, is nearly out, and in the next the cause shall be omitted, and the rest rewritten. In conclusion, I tender you my warmest thanks for your observations on the trial, which I must confess I expected from you, as the *Lancet* has ever been the consistent and vigorous—the earnest and unflinching advocate of the medical man when he has been assailed by ingratitude, rapacity, or malevolence. And apologizing for intruding so largely on your space,

I am, Sir, yours &c.,

EDWARD T. ROE, M.D.,

Princes Square, Plymouth, Sept. 25, 1852.

Medical Intelligence.

(From our own Correspondent.)

LONDON, OCT. 11, 1852.

Notwithstanding that the official reports from those districts on the Continent where the epidemic cholera has been for now many months destroying the population by hundreds and by thousands, show that that disease is everywhere, save in Berlin, markedly on the decline, so that from some of them no further reports will be issued; and that, in the sole exception, Berlin, the number of cases daily does not exceed, even if it amount to, ten, our wise Government have, at the eleventh hour, determined to wreck commerce by the most futile of all expedients, yecept *quarantine*, which, as a measure of prevention, even when employed on the largest scale, has been shown over and over again, to be utterly useless. If by a *cordon sanitaire* the entire kingdom could be thoroughly and effectively encircled, it would be utterly ineffective; because there can never be a thorough quarantine against the atmosphere; and that some of the least of the causes of epidemic diseases are atmospheric, cannot admit of a doubt. We do not purpose opening a discussion on the thread-bare questions of contagion and infection, but simply to express our firm belief that the atmosphere exerts a well-marked influence in the production of epidemic diseases; and that, consequently, all quarantine regulations are utterly useless. For some weeks, or even months, before a country is invaded by an epidemic disease, about to become universal, there is an evident increase in the extent and malignancy of other zymotic maladies and epizootic diseases, while maladies affecting the products of vegetation are also generally prevalent throughout the length and breadth of the territories so threatened. This has been for a long while past, the

condition of the Continent of Europe; and in this state the British Islands are now to be found. And yet our Government propose to arrest the onward march of the epidemic by quarantine measures!

When such proceedings are attempted to be carried out by the governing powers of one of the most civilised and most highly educated states in the world, "one is really tempted," to use the words of the *Times*, "to suppose that investigation is a waste of time, the acquisition of knowledge a needless strain of thought, and the detection of error a worthless waste of labour. No point we believe to have been better settled than the futility of quarantine as a precaution against cholera; and, what is more mortifying still, this country led the march of public opinion on the subject, and forced by its arguments and authority, a conviction on the mind of Europe, similar to its own;" and while the remainder of the European powers, influenced by the result of the Sanitary Congress, lately held at Paris, have utterly abandoned all quarantine regulations, England, hitherto in the van of all social and political improvements, is to stultify itself by again having recourse to them. This, then, is the result of the visits lately paid at the Home Office, by the octogenarian man of one idea, Sir William Pym! He can see nothing but disease and infection in his fellow-creatures, and their clothing and merchandise, and to gratify and enforce his exploded views, the extensive commerce of this great country is to receive a heavy blow and a great discouragement. We had hoped that all such measures were buried deep in the tomb of all the capulets.

The Privy Council have issued a letter to the Commissioners of Customs, requiring them strictly to examine all vessels arriving from the eastern parts, and if any person shall be ill of the cholera, or have had it within a few days of his arrival, to detain the vessel under a precautionary quarantine, for such a period as a medical officer shall judge necessary for the security and preservation of the health of the community. To stamp the inutility of the measure the more completely, it is added, that this being only a quarantine of observation (What is that?) to prevent the person suffering from disease from communicating with the shores, no restraint is to be placed on persons on board enjoying good health, whether passengers or crew; they may be permitted to have the same free communication with the shore, as if the yellow flag had not been hoisted, and thus practically do away with whatever benefit might be expected from the measure; because persons may be apparently well, and yet have the seeds of the disease fermenting in, and decomposing the blood, throughout its whole course, during the period of incubation, and thus be fully capable, according to the doctrine of the contagionists, of imparting the malady to the sound and healthy on shore, with whom they are to be permitted to come in contact. How is it that governments have such a plentiful lack of wisdom? Oh that it were possible to inoculate them with common sense. What a vast benefit might thus be conferred. To gratify the mistaken whims and fancies of a one-ideal octogenarian, the vast commerce of this country is to be jeopardised, and its character for consistency and sense forfeited, by the adoption of a measure which cannot by any means effect its proposed object. *Proh! pudor.* [The remainder of this letter arrived too late for insertion.—Ed. J.]

GRATIFYING TRIBUTE TO A SURGEON.

The Miners of Tywardreath and its neighbourhood, appreciating the valuable services of Mr. Taylor, resolved on presenting to him some tribute of their esteem and regard. A subscription was set on foot, and the result has been the purchase of a handsome and costly tea service, which was presented to Mr. Taylor, at a meeting in the Market Hall, on Saturday evening last; the testimonial having during the day been exhibited in that place to many hundreds of those who had contributed to its purchase. Mr. W. E. Geach presided at the presentation; and, after Mr. G. Job, the Secretary, had read the address to be presented with the testimonial, and to which were affixed the names of the subscribers, the President, in an able and appropriate speech, presented the testimonial—a handsome silver-gilt tea service. On the tea-pot is engraved on one side the family crest of Mr. Taylor, and on the opposite side the following inscription:—

Presented to
William Wale Taylor, Esq., M.R.C.S.,
Surgeon of the Fowey Consols, Par Consols, and
Tywardreath Mines, &c., &c.,
by five hundred Cornish Miners, and other
Friends, as a Tribute of their respect and esteem;
And also in grateful recollection
of his skilful professional services
and many kindnesses
received by them during a period
of fifteen years,
Midsummer, 1852.

Mr. Taylor, with much emotion, returned his thanks for the gratifying tribute. Votes of thanks were carried by acclamation to the Chairman, the Treasurer, and the Committee, which were severally and suitably acknowledged; and this terminated one of the most pleasant meetings ever known in Tywardreath.

ROYAL COLLEGE OF SURGEONS.

It may not perhaps be generally known, that by recent regulations of the Council, a Board of Examiners in Midwifery has been established, consisting of the senior Vice-President of the College, together with Dr. Arthur Farre, Dr. Henry Oldham, and Dr. James Reid. The conditions under which candidates are admitted have just been published, from which it appears that persons who are, or shall become fellows or members of the College prior to January, 1853, will be admitted to examination on production of their diploma; other gentlemen becoming members subsequently to the above date, will be admitted on producing, with their diploma, a certificate of having attended twenty labours. From the same regulations it appears that members or licentiates of any legally constituted College of Surgeons, or graduates in surgery of any University requiring residence to obtain degrees, will also be admitted to examination on producing, with their diploma, certificates of being 21 years of age, of having been occupied four years in the acquirement of professional knowledge, of having attended one course of lectures on midwifery, and of having attended not less than twenty labours. There are other regulations on the above important subject, which may be ascertained on reference to the Secretary at the College.

APPOINTMENT.

Dr. Wood, who recently resigned his appointment of resident medical officer of Bethlehem Hospital, has been licensed by the Commissioners in Lunacy, and has entered upon the management of Kensington House Asylum, lately conducted by Dr. Philp.

ROYAL COLLEGE OF PHYSICIANS.

At a quarterly meeting of the Comitia Majora, held on Thursday, Sept. 30th, the following gentlemen were admitted Members of the College:—Dr. Druitt, 39, Curzon Street, Mayfair; Dr. Gibbon, St. Bartholomew's Hospital, Dr. Hill, Bath; Dr. Ottley, Pau, Lower Pyrenees; Dr. Pantou, Turriff, N. B., were also admitted Extra-Licentiates

SOCIETY OF APOTHECARIES.

Gentlemen admitted Members, Thursday, September 30th, 1852:—William Edney; Richard Hosking, Marazion, Cornwall; Samuel Buckland Mitchell, Kingston-on-Thames; John Slack Steel, Ardwick, near Manchester; Robert Francis Symmons, Bures, near Colchester, Essex.

Names of Candidates who passed the Classical and Mathematical Examination on Saturday, October 2nd, 1852:—Joseph Dixon Adams, Martock, Somerset; Alexander E. Bartlet, Ipswich; Robert L. Bett, Spalding, Lincolnshire; Thomas Cayzer, Southampton Hospital; Thomas E. Clark, Redland, near Bristol; John Andrew Ferris, Aldersgate Street; Charles H. Fisher, Bungay; Edward Footner, County Hospital, Winchester; Thomas Foster Gray, Leicester; Thomas C. W. Henchley, Ashbourne; James Hine Lihou, Guernsey; James Richard Lownds, Newcastle-upon-Tyne; Frederick John Mason, Wisbeach; Henry Maudsley, Settle, Yorkshire; Charles Roberts, Gloucester Terrace; Francis Scott, Reading; William Alfred Skinner, Bath; William Sly, Wincanton; Henry Banks Spencer, Chippenham; Adam Taylor, St. Paul's Churchyard; Thomas S. Walker, Burslem; William Spencer Watson, Southampton Street; William B. Winkfield, Bedford; Edward Woakes, Luton, Bedfordshire; Alfred Woodforde, Welbeck Street.

Gentlemen admitted Members on Monday, October 4th, 1852:—H. C. Andrews, Chapel Street, Belgrave Square; Francis E. Ansie, Devizes; N. P. Blaker, Sussex County Hospital; John Meaburne Bright, Alvaston, near Derby; William Thomas Carr, Newcastle-on-Tyne; Thomas Carter, Newbury; J. M. Donne, Bath; Francis Joseph Dowling, Chew Magna, Somersetshire; F. Fawcett, Wisbeach; Michael Foster, Huntingdon; William Tilbury Fox, Broughton Stockbridge; Hamilton Downe Gundry, Vernon Place, Bloomsbury; John Husband, Wellington; W. F. Johnson, Colchester; Edward William Jollye, Hammersmith; Henry Knaggs, Huddersfield; Henry Leach, Wisbeach, Cambridgeshire; Bernard Piffard, Whitehart-lane, Tottenham; E. H. Pitman, Manchester; William Howell Pix, Tunbridge Wells; James Procter, Congleton; William Puckle, Sussex County Hospital; David Rice, Stratford-on-Avon; J. Charles Thorowgood, Totteridge; William Meymott Tidy, Cambridge Heath, Hackney; B. M. Walton, Hampton, Middlesex; John Warren, Worthing; Thomas James Woodhouse, Philadelphia-place, Hackney; Francis Workman, Reading.

TO CORRESPONDENTS.

Communications have been received from Mr. Ranking, Dr. Crisp, Mr. Langston Parker, Nil Desperandum, Mr. Collins, H., Mr. Limbird, Mr. John Jones, Dr. Tilt, Mr. Sands Cox, Dr. Robertson, Mr. Higginbottom.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

INTRODUCTORY LECTURE,*

DELIVERED AT THE

LEEDS SCHOOL OF MEDICINE,

OCTOBER 4TH, 1852.

By THOMAS NUNNELEY, Esq., F.R.C.S.E.,

President of the School for the ensuing year.

Printed by desire of the Council of the Leeds School of Medicine.

ENOUGH has been said, I trust, to show you the very intimate bearing such researches have upon our own immediate professional pursuits; to illustrate the extended and comprehensive grasp which it is most important for you always to seize upon in your reasoning processes. Remember the term *human physiology*, if it be used, as it certainly has too often been employed, as though there were something peculiar and individual in the function of man's organs, is a mistaken one, and one which is likely to lead to error. If we wish to know human physiology well, we must understand *general physiology*, of which it is only a part—an important one, doubtless, but still nothing more than a part.

To *PHYSIOLOGY* we naturally have added *PATHOLOGY*. From the knowledge of the action and function of a part in health, we are directly led to consider the altered conditions which are presented by it when diseased. Upon this, evidently, all scientific practical as well as theoretical medicine must rest, consequently, to pathology you must necessarily pay much attention: indeed it will be forced upon you; for in the lectures upon both medicine and surgery, allusion must constantly be made to the altered condition of parts in connection with the phenomena of disease, as well as to the application of remedies for the removal of such disorders. In this course it is the diseased condition itself—the structure which is found to occupy the seat of the original tissue, constituting *morbid anatomy*—in which you will be instructed; while in the two other courses it is rather to the consequences of these alterations, their effects upon the living animal economy, and the proper means to be adopted to prevent or remove them, than to the alterations themselves. *Physiology* and *pathology* constituting ground common to the scientific anatomist and the well-informed physician and surgeon.

The study of anatomy may be pursued by two very different methods; according to the one the various parts of the body are considered principally with reference to the forms which they present, the exact situation which they occupy, their relative proportions, and the manner in which they are connected with each other. This, which is now commonly called *descriptive anatomy*, is admirably adapted for learning the details of the structure of the body; and, accordingly, it must be adopted in pursuing human anatomy. It is the method which is adopted in the demonstrative course

of anatomy. The second method is to group all those parts together which are possessed of a similar organization and analogous functions, and to consider them as portions of a common whole. This plan, which is denominated *general anatomy*, is exceedingly well calculated to assist us in studying the physiology and pathology of tissues; since it is a well-known law that, wherever situated, the same structures are endowed with the same properties; but it is not at all adapted for teaching the size, situation, form, or connection of different parts. Now, as we must never forget that the end of all our study should be to make us good practitioners, the system pursued will be a combination of the two methods. In the lectures, general anatomy will form the first division; the description of the structure, function, and morbid alterations of the individual organs will follow. But in the demonstrative course your attention will at once be drawn to the descriptive details of the different parts, beginning with the bones, of which let me again entreat you to resolve to acquire a full and accurate knowledge. Inasmuch as they form the solid basis and groundwork of the whole fabric, it is especially necessary thoroughly to understand them. The importance of this I cannot exaggerate; at present the younger student, to whom I this day principally address myself, can scarcely conceive how much his future progress, not merely while a student, but during his whole life, will be facilitated by so doing. Next to the bones, the means by which they are connected together, and the different articulations formed, must be considered. These—the bones and ligaments, form the passive organs of locomotion; the active, or the muscles, naturally follow. Subsequently the apparatus by which these are nourished, directed, and kept in control—the viscera, blood-vessels, nerves, brain, and organs of sensation—will claim your attention.

This plan must only be considered as that which is best adapted for pursuing anatomy practically, and principally for acquiring a knowledge of the minute formation of the human structure, which is what we have to do. Were this not the primary object, other classifications of a more strictly scientific character, for systematically investigating the proportional development of parts might be adopted. Thus we might with *CARUS* divide the organs into vegetative and animal under the first term including all those which are common to plants and animals, upon which depend such functions as nutrition, growth, respiration, secretion, and reproduction; while the second comprises only those parts which are peculiar to animals, as the muscular, nervous, and sensorial. Or we might employ another method, classing and describing organs according to their importance in the animal economy, and the influence which they exercise over its other components. In this latter arrangement it is clear we should follow a course nearly the inverse of that which it is proposed to adopt; for here it would be necessary to commence with the nervous system, since it is the all-important agent and directrix in the organization and modification of the others; for to correspond with its variations, and to be adapted to its demands, do they seem to be

* Continued from page 529.

moulded and altered; inasmuch as the more elevated and noble position of man, as well as the controul he exercises over other animals, depends upon the much higher degree of his intellectual and moral qualities, which are dependent upon increased development of certain portions of the nervous system.

In this place it appears proper, though I can hardly consider it necessary, that I should guard you against falling into an error, which has by some been thought to be one of the besetting sins of anatomical pursuits; that which is vulgarly called materialism—a mistake into which only weak or imperfectly-educated minds can fall; or, at least, those who reflect so little as to confound terms and things which in reality are distinct. This error, in point of fact, is one which is not peculiar to the anatomist, but is equally liable to beset all those whose studies lead them to contemplate the phenomena of matter, whether organic or inorganic, where the admirable dependency and connection between cause and effect; and the invariable constancy with which the same sequent follows the same antecedent, may probably induce some to limit their ideas to the material itself, and to overlook the important fact, that the portion of matter which is endowed with such wonderful and energetic properties, when resolved into the elements of which it consists, presents comparatively little variation from other portions of matter which are endowed with very dissimilar, though equally wonderful properties, and that before it could have possessed such astonishing qualities; admitting that these result from the organization or mode of arrangement of the individual atoms of which it is made up; it was absolutely necessary some infinitely wise and omnipotent power should have impressed upon it those laws of arrangement upon which its properties depend. Surely when we say that a higher grade of existence is dependent upon a higher state of organization, that animals who possess endowments of a superior order, or that even man himself owes supremacy to increased development of the same organs which are possessed in an inferior and more imperfect condition by lower classes, there is nothing incompatible with the firmest belief in an overruling and creating power; on the contrary, to my mind it appears necessarily to call forth feelings of a totally opposite character. When we see elements of the same nature, with but little alteration in their proportion or modes of arrangement, constituting organs capable of producing such different effects, and in each case so admirably adapted to the wants and necessities of each and every being, we are inevitably, and almost unconsciously, led to trace the primary cause up to a power so omniscient and omnipotent, as well as benevolent, that the mind is lost in amazement. So far is the sameness of material, or similarity of arrangement, from checking our admiration, it is this very simplicity which impresses us with the conception of grandeur, immensity of design, and perfection of execution, which from such simple materials has been enabled to organize a creation so perfect, as to appear a necessary result of that matter which this power has called out of chaos into light and order.

"Won from the void and formless infinite,
 * * * * * a dark
 Illimitable ocean, without bound,
 Without dimension, where length, breadth, and height
 And time, and place, were lost: where eldest Night
 And Chaos, ancestors of Nature, held
 Eternal anarchy, amidst the noise
 Of endless wars, and by confusion stood;
 For hot, cold, moist and dry, four champions fierce
 Strove here for mastery, and to battle brought
 Their embryon atoms. * * * * * This wild abyss,
 The womb of nature, and perhaps her grave,—
 Of neither sea, nor shore, nor air, nor fire,
 But all these in their pregnant causes mix'd
 Confusely, and which thus must have ever fought,
 Unless the Almighty Maker had them ordained
 His dark materials to create more worlds."

Indeed so impressed am I with this, that I know of no pursuit so likely as is anatomy, with its kindred sciences of physiology and pathology, when properly cultivated, to lead its followers up to a high and lofty conviction of the existence of a God.

Such, then, gentlemen, is a hasty sketch, or rather a very general outline of the subjects to be brought before you in some of the courses of lectures upon which you have now entered. The acquisition of all this information may, probably, appear to be difficult; from its extent much labour and steady perseverance will necessarily be required, but then it will amply repay any exertion and self-denial it may demand, because it constitutes a very large part of medical science. Indeed, when to it is added *THERAPEUTICS*, or a knowledge of the action and properties of the remedial agents employed, we have embraced almost all that can be said to be *directly* and *immediately* included under the term medicine, not by any means that it comprehends *all* the knowledge remaining to be possessed by the practitioner, which must be drawn from many sources. Independently of what is immediately and directly connected with medicine, there is scarcely a division in the widely-extended range of either science, literature, or art, which is not more or less allied with our inquiries and studies. Pursuits which may appear at first sight so remote from ours, that a neglect of them can apparently be of little importance to our investigations, are found so to elucidate the phenomena of health, or explain the effects of disease, which were before inexplicable, that an acquaintance with them is not merely useful, but at times absolutely necessary, to a right comprehension of many physiological and pathological facts.

From the earliest formation of our bodies, until the period when they are resolved into the elements from which they were originally derived, an incessant and complicated change is going on. By digestion, assimilation, and secretion, there is a constant reception of new particles into the body, by a conversion into itself of extraneous and foreign matter, while there is as constant a removal of the old particles from the body. These processes, if not in themselves, as I firmly believe them to be, of a strictly chemical nature, are so intimately allied to it in health and in disease, are so closely under its influence, that before they can be in any degree understood, some very considerable acquaintance with chemistry is necessary. Though we may not regard as *facts*, to be received as *undisputed truths*, all the statements which modern chemical physiologists have

put before the world as the result of most laborious researches, and which many high authorities appear inclined to consider as true, regarding the manner in which animals are nourished, by simply extracting the proximate principles found ready manufactured for them by the plant they consume; nor adopt every assertion of the pathological chemist, as to the very simple chemical alteration constituting the differences between healthy and diseased secretions and excretions, whether solid or fluid; yet, unquestionably, the importance of these inquiries cannot be too highly estimated, and every additional step in our knowledge shows the increasing value of these studies. The administration of remedies, both in the ordinary diseases to which man is heir, and as antidotes, when by accident or design, noxious and poisonous agents have been swallowed, is very frequently a mere question of chemistry, and the detection of a deleterious substance is almost always dependent upon an intimate and practical acquaintance with chemical analysis.

The blood in passing from the right side of the heart, in its progress through the lungs, to gain the left or systemic side, loses the deep claret colour of venous blood, and acquires the bright red hue of arterial. By being subjected to the influence of the air this change occurs, and the blood becomes again fitted for the support of life, the air itself at the same time undergoing very considerable alteration in its composition; but without an acquaintance with the properties of atmospheric air and other gases, how could we have been aware of the nature of this process, or the effect thereby produced upon the whole body? Without this knowledge the whole subject of animal heat—that most wonderful, and, until explained, mysterious power of animals maintaining their bodies in a temperature so different from that of other substances, by which they are surrounded; but which we now know to be a simple question of combustion, almost as simple as the regulating of a furnace fire is to the degree of heat desired to be produced, would have been incomprehensible. The purposes of such variety in the circulatory system and such different arrangement in the respiratory apparatus;—why one animal should be possessed of lungs and another of gills;—or why one creature should live and have its being upon land, but be immediately deprived of life if immersed in water; another move with vigor of health in the water, but directly perish upon land, would have remained a secret and a mystery. For this and much knowledge of a like nature bearing upon vitality, we are indebted to CHEMISTRY; and hence, not only is a knowledge of this science useful to the student of medicine, but absolutely necessary, since it is one of the subjects, the study of which is enjoined by all the Examining Boards of every country in the world.

The bones and muscles are so many illustrations of dynamics. Though muscular contractility in itself be a vital agent, yet in its modification it obeys the strict and unchanging laws of mechanics. The bones are so many inert levers, and the muscles the powers by which these levers are moved; in doing which there is either

loss of power and gain in velocity, or loss in velocity and gain in power, precisely as there would be were the muscles so many leather straps, and the bones so many pieces of iron or wooden machinery.

The arrangement and distribution of the circulatory system is in strict accordance with the laws of HYDROSTATICS, and were an engineer to be called upon to convey a fluid to and from a central point, over a large surface, so that its propulsion should require the least expenditure of power, and yet that the decrease in its impetus should be gradual and progressive, he certainly could not take a better model than the heart and bloodvessels. The angles at which the vessels divide is that which gives the least resistance to the progress of the blood, and the increased capacity of their distal branches, causes a diminution in the blood's velocity, while the elasticity of the arterial coats ensures a steady onward flow. The construction of the valves of the heart is a perfect piece of mechanism and need be merely indicated as an imposing illustration of the importance of bringing all our knowledge of MECHANICS to bear upon anatomical questions: for upon the due appreciation of the sounds produced by those valves how much of hope and misery for our patients hang! Of this, hereafter you will recognise the truth.

Without some knowledge of the mode in which SOUND is produced, and the manner in which it is conducted through different media, how could we appreciate the delicacy and intricacy of the mechanism of the ear? or, still more, how, without some considerable acquaintance with the physical properties of LIGHT, and the laws of its refraction and reflection in passing through, or being reflected by, media of different densities and forms, would it be possible to understand the value of such varied, delicate, and beautiful arrangements as are found in that glorious and important organ, the eye? Or how could we manipulate with advantage, that latest of helps to our investigations of the minute structure of healthy parts, and the changed conditions of morbid products, which modern science and mechanical skill have presented to us—the microscope? the importance of which is daily becoming more appreciated by the scientific practitioner, notwithstanding the temporary slur which may not improbably be cast upon it, by the very questionable use which is apt to be made of it as a means of astonishing and bewildering the ignorance of patients, by an ostentatious parading of its powers by those who, themselves, as little know or appreciate its true value as the persons they are practising upon.

By GEOLOGY we obtain a knowledge of the condition of the earth in ages long passed away, and the influence this condition has in all times had upon its inhabitants; and are taught that the many extraordinary, and, according to ideas derived alone from the present forms of animal life, monstrous and mishapen masses of created beings, were in as perfect harmony with the then existing condition of the globe, as those forms by which we are surrounded, and which are universally regarded as perfect, are to the present condition of the earth. We learn not only the nature of the surface of the soil,

but also that of the rocks and strata underneath, by which we may often obtain an explanation of the healthiness or unhealthiness of different localities, and why one situation may be better adapted as a residence for those affected with one complaint, and the opposite situation for those labouring under another ailment; why a disease is epidemic in one place or endemic in another. While METEOROLOGY enables us to explain in the some degree, (and a better acquaintance with the science will doubtless do so in a far higher degree) the laws which regulate the apparently irregular and capricious appearance and disappearance of many devastating diseases which, from our inability to explain many of the phenomena manifested by, or to efficiently control the course of, are now popularly regarded as the appropriate of medical science.

By MINERALOGY we are taught the properties of those metallic substances which mechanical skill has converted into the wealth of nations, and which chemical science has metamorphosed into such potent and valuable remedies for our use in combating disease; and BOTANY furnishes us with most important information respecting the nature and properties of those plants which furnish so large a portion of the food of all animals, as well as of those which supply the vegetable agents which enter so largely and importantly into the practice of medicine; enabling us, by a study of well-defined organization, to readily ascertain to which class any new kind of plant should be referred;—amongst those which furnish food, clothing, or habitation to animal and man; those which supply us with the means of combating disease; or amongst those which are without much value, or positively injurious to animal life.

Thus might I pass in succession over every branch of knowledge, whether of literature, science, or art, and show how each may be brought to bear upon our own particular pursuits; but I forbear, as time will not allow. That the man who brings to the study of the healing art the greatest store of theoretical knowledge, and skilful practical application, gathered from varied sources, will, *ceteris paribus*, be the most successful practitioner is self-evident. There is only one other point to which I will direct your attention, and to this I beg your earnest and careful heed. It is to strive to become *careful observers and correct reasoners*. These are the two main safeguards for your success in legitimate medicine, or in any other honourable career. It is the want of these two qualities which has proved the bane of so many;—the want of power to distinguish between the *post hoc* and the *proper hoc*; the confounding of sequent and antecedent with effect and cause;—the non-development or non-cultivation of the reasoning faculty. To this do we owe such a multitude of false facts, so many absurd theories, such pernicious heresies, and so many fatal and disgraceful professions of faith and practice—"the brood of folly, without father bred." Cultivate these two powers—correct observation, and the faculty of reasoning correctly from what is observed, you will not then go far wrong. These are the safety anchors in after life: possess them you will be wise; without

them no amount of book learning can make you so. You may be clever and ingenious, but never safe; plausible and showy, but never profound, or to be relied upon. I speak here decidedly; if I did not I should not speak honestly, for I feel strongly. Had the profession as a body cultivated logic more successfully, it would not have been disgraced by so many of its members disgracing their brethren and degrading themselves by the adoption and profession of absurd and senseless imaginings, which they are weak or wicked enough to proclaim as new theories. Had the reasoning powers been properly cultivated, that most jejune and idle of all fancies, "that with gaudy shapes possess the idle brain," as thick and numberless

"As the gay notes that people sunbeams,
Or likest hovering dreams,—
The fickle pensioners of Morpheus' train,"

could have had no being. Hahnemann might have lived; but homoeopathy could have had no existence. People might have lived and died without being physicked *secundum artem*; but they could not have been befooled out of the world by the decillionth part of a grain of an inert substance: they might have died naturally, had they so fancied; but, at any rate, the professors of medicine would not have been disgracefully mixed with the dreadful scene. No, gentlemen, become capable of reasoning in ever so small a degree;—become, to some small extent, observers of nature;—possess some knowledge, however minute it may be, of the chemical and physical properties of different substances;—do obtain some little information about the action of remedies;—in some small measure become acquainted with the natural course of disease;—do recognise the existence of what every physiologist has for ages known and valued as an important part of his duty to study, the *vis medicatrix nature*;—and you will become incapable of being homoeopaths; unless your moral perceptions should unfortunately be so lamentably obscured as, for the sake of mere temporary gain, to sink into being the panderers of popular or fashionable delusions, so surprising as to be almost as wonderful as the expenditure of such a magnitude of belief, upon means so utterly contemptible and insignificant, is astounding; and thus, while knowing better, consent to act so reprehensible and immoral a part.

But it may be asked,—Why do I enumerate all these difficulties—to damp the ardour of your desires, or to check the enthusiasm which should animate you at the commencement of a session? Certainly not; but rather to stimulate and encourage you. By fairly knowing what there is to be encountered, you will be prepared for the task, and thus not be liable to shrink back with dismay or disgust when the difficulty is half surmounted. It is infinitely better that the magnitude of any undertaking should be appreciated in the outset, so that the resolution and means may be apportioned to the requirement needed, than that we should enter blindly upon a career we are unequal to. You must not under-estimate the serious responsibilities of the profession you have entered upon. I know of none which involves greater—of none where the labour is

greater—of none where the same wide range of study, thought, and care, are demanded, and may advantageously be brought to bear; nor of any which is more honourable to its professor, or more useful and advantageous to mankind. In entering upon any pursuit of life it is only right we should be fully impressed with what is required of us; otherwise we cannot excel in it. There is, I believe, no other avocation which demands such constant and unremitting perseverance as our own, in qualifying ourselves for the exercise of our profession, as well as self-denial in the practice of it. The prospective, however, is often more formidable than the reality will be found to be. Of much of the information most of you are already, or should by your preliminary education be, possessed. By attentive study, taking great care not to attempt too many branches at once, but always thoroughly to understand that upon which for the time being you are engaged, you will find there is something so enticing and alluring in the acquisition of knowledge, the possession of one fact leads on so pleasantly to another, that so far from the habit of study being wearisome, it will be found, after the first difficulties are overcome (and depend upon it there is not any path of life without them) that, were there no ulterior objects, the possession of the information itself would be a sufficient remuneration for all the labour bestowed in obtaining it.

But there are ulterior objects, and these the most powerful which can influence any human being. Your duty to yourselves, to your relatives, and to your country, demand it. I will not allude to the greater difficulty now than formerly existed in obtaining admittance through the portals which guard the profession of which you are the disciples, nor to the greater amount of knowledge, both general and scientific, which it has pleased the presiding powers of most, if not of all, the ordeals which you must pass, most properly to require before you can be allowed to enter within its honourable precincts; those requirements are only in accordance with the increased means of obtaining information which you possess over most of your predecessors; for though I am not more than a middle-aged practitioner, I have lived long enough to perceive a great improvement in both the quantity and quality of the means and appliances for medical education.

Moreover, examinations, be they conducted wherever they may be, can only be framed for the many, and must necessarily be apportioned to the average qualification of the mass. Such being the case, it would be an insult to you to suppose your ambition is limited to the paltry endeavour of acquiring only such a modicum of knowledge as shall ensure you passing unscathed through the trial to which the law requires you to be subjected. No: little likely would that individual be (and I trust no student of the Leeds School of medicine will be of such a temper,) to distinguish himself in after life, even though by the disgraceful system of *grinding* he should succeed in cramming into his head, *pro tempore*, just sufficient knowledge to enable him to gain admission to our rank. You must never forget that it

is not alone in the profession of medicine that an increased amount of information is required of its professors; such demand is only in accordance with the spirit of the times, and the increased knowledge which is now happily so widely and generally distributed among all classes of the people. You must remember, that medical men hold their rank by no prescriptive right, nor is their position due to legislative enactments; the mere privilege of writing any number of letters after a name, becomes an idle mockery, unless it be accompanied by suitable acquirements. It is not the name of physician or surgeon which has raised the medical profession to the respected position in which, (notwithstanding occasional sneers, *when its services are not needed*,) it is deservedly held by the public, but the moral truth and intellectual attainments of its members which has rendered the name honorable; and depend upon it, that only so long as are to be found in our ranks the zealous and successful cultivators of science, and the active benefactors of mankind, will that deference and respect which it has for so many ages enjoyed, be conceded or deserved.

Your immediate relatives and friends have a strong claim upon your gratitude, which should be evinced by a continued and respectful attention to your studies, and to your instructors. Having placed you in an advantageous position by the expenditure of much care, and a large outlay of money, they follow you here with solicitude, and it would be a poor return for their kindness, should you neglect to take every advantage of the opportunities which are placed within your reach; and, let me add, that even though you should labour with a praiseworthy diligence in the acquisition of knowledge, in order to make this available, with honor and advantage to yourselves, and with benefit to the community, it must be accompanied by a well-regulated deportment, and correct moral conduct, without which you neither can nor deserve to obtain, the friendship, respect, and confidence of the wise and good. Never forget that a medical man ought to be a gentleman in his habits as well as in his education.

And lastly, our country has claims which are strong and imperative. Professing, as we do, by a long course of study, and a peculiar routine of education, to qualify ourselves for the responsible duties of removing pain and disease, and warding off the approach of death, our patients have irresistible moral claims upon us, that when confided to our care they shall receive the best counsel, not that we may happen to give, but the best that can be given, and which it is our bounden duty, religiously, to qualify ourselves to give, upon which depends our being the most useful, or the most dangerous and mischievous members of the community. It will happen to each of you, probably more than once, to be summoned to a court of justice, where, very possibly, the sentence depends almost alone upon the medical evidence. What would be the responsibility if, through your ignorance, the guilty should escape, or still more, if the innocent should suffer? Though it can only be the lot of few to be intrusted with the lives of those great men who, by their learning, writings, or mechanical

skill, have become the common property of the whole world; or who, by their wisdom and eloquence in the Senate, change the destinies of empires; or those upon whom, from their genius in the camp, the fate of nations hang; yet it must daily, and almost hourly, occur to every one of you, however limited and humble his sphere may be, to have the charge of the health and life of his fellow-creatures; and though possibly the grave may tell no tales, nor friends blame us, yet how can we shun the harrowing reproaches of our own conscience, if through our ignorance or neglect any human being shall be hurried to that "undiscovered country, from whose bourne no traveller returns." Perhaps—

"Cut off even in the blossom of his sin.
Unhous'd, disappointed, unannc'd;
No reckoning made, but sent to his account
With all his imperfections on his head."

Can there be any higher claims upon our exertions and industry? If there be, I confess to know them not.

The sciences of anatomy, medicine, and surgery, are, after all, not so very hard to be acquired. True, they are surrounded by difficulties, but these are to be overcome by patience and labour. In this as in every other pursuit, genius and imagination will avail their possessor much, but remember, nothing will compensate for steady and constant attention. You all recollect the fable of the hare and the tortoise; the moral of it is well worth constantly bearing in mind by every student. Practical anatomy consists of facts and observations, which are only to be learnt by actual inspection in the dead body; therefore, let me impress upon you the importance of dissection. Depend upon it the more you dissect now, the more satisfaction you will have hereafter. In this school there is no excuse for not becoming competent anatomists, because there is every facility for acquiring a knowledge of it. Our arrangements for obtaining subjects are such that for many past sessions the supply has been so abundant that not all has been used. I trust in this session, not that the supply will be less abundant, but that the demand will be greater. I think I have observed, not only here, but generally, there has been a growing disposition to rely upon those well illustrated and beautifully got up works upon anatomy which have of late years issued from the press, rather than to undergo the trouble and drudgery of dissection. Against this let me warn you. Illustrations and plates are most valuable assistants and capital refreshers; but they cannot teach anatomy. No man was ever made, nor ever will become, an anatomist in this manner. To become an anatomist there is no very short cut—no royal road to proficiency; the only way which is open to its votaries is that by which so many of our predecessors have ascended the rugged path of eminence—careful and repeated dissections.

CLINICAL LECTURES

ON

VENEREAL DISEASES OF THE SKIN,

DELIVERED TO THE

STUDENTS OF QUEEN'S COLLEGE HOSPITAL, BIRMINGHAM.

By LANGSTON PARKER, Esq.,

One of the Surgeons to the Queen's Hospital, etc., etc

PUSTULAR SECONDARY SYPHILIS.

GENTLEMEN,—We have now in the wards of the Queen's Hospital, several cases of venereal diseases of the skin of the pustular kind, and as this is one of the most important and frequent of the secondary or constitutional forms of syphilis, I shall draw your attention to them in this lecture.

Pustular syphilis is characterised by the eruption of pustules of various sizes, over a greater or less extent of the whole surface of the body, rarely accompanied by any symptomatic fever. It is sometimes confounded with other forms of skin disease, not venereal, on the face. I have known it mistaken for acne, especially when the pustules are small, and I have also in more than one instance seen it mistaken for small-pox, and this very lately. Pustular secondary syphilis assumes several forms; in one form the pustules are small and numerous, this has been termed the lenticular or miliary pustule; in a second form the pustules are larger and not so numerous; and in the third form we have large single pustules, irregularly disposed, but not numerous, the patient may have from ten to twenty of these pustules, in different stages, on various parts of the body. It is fortunate that for the illustration of this lecture, there are patients in the hospital with each form I have described—two in Victoria ward, and a third in the lower mens' detached ward; again, we have one or two out-patients with the same disease, and in one case I have had casts made of the eruption at different stages of its progress, in order to show you those changes in the pustule, which I am about to describe. [The casts were here exhibited to the class.] The secondary syphilitic pustule is a very common form of constitutional syphilis. It generally occurs from six to twelve months after the primary poisoning, but I have seen cases, one now in the hospital, where a well-marked pustular eruption occurred before the primary sore was healed; and again, I have known well authenticated cases, where pustular syphilis has occurred ten, twelve, twenty-seven, and thirty years after a primary infection. It is difficult to explain these facts which I state from my own experience, and in which I am borne out by M. Cazenave;* of their truth there can be no doubt.

The syphilitic pustule runs a very marked and peculiar course, and I will take a medium-sized pustule for the purpose of illustrating the history of this course, because the progress I am about to mention, is not so

* *Traité des Syphilides.*

well marked either in a very small pustule, or a very large one. When the syphilitic pustule first appears on the skin, it consists of a portion of epidermis raised by a small quantity of pus, but the disease remains a very short time in this state, sometimes only a few hours, at most not more than a few days; the pustule becomes ruptured, the pus exudes on the surface of the pustule, which shrinks and dries up.

In the first form, (the lenticular), the pustules commence in small, red, elevated spots, spread more or less over the face, trunk, and extremities; these spots suppurate at the apex, and each spot contains a drop of matter about the size of a large pin's head; the pustule soon breaks, the pus exudes and dries on the surface of the pustule, each of which is then covered with a small crust, slightly depressed in the centre. On the face these pustules very much resemble "acne."

In the second form the pustules are larger, about the size of a pea, or the small-pox pustule, these soon break and become covered with a thin, flat, or conical crust; if the pustules are few and isolated, the crusts are circular, but if near together the crusts run into each other and assume an irregular form. The disease, in this stage, has been denominated "pustulo-crustaceous." We may see the pustule before it has broken, surrounded by a narrow, red, or livid areola, or the circular crust where the pustule has ruptured, and the pus dried up, or confluent and irregular where the pustules have been near together.

The crust covers an ulcer which, when the former is detached, may be found in varied conditions, either healthy and disposed to heal, deep and sloughy with indurated edges, or even phagedenic. These are secondary venereal ulcers, succeeding to the rupture of the pustule. The ulcer may heal under the crust of the pustule, which is a very common circumstance, but when it does so it leaves behind it a red cicatrix always more or less depressed in the substance of the skin. If the pustule have been placed on the forehead, and have been large and long in existence, the surface of the bone is always more or less absorbed, and a well-marked depression exists in it, long after the ulcer has healed, and the skin has recovered its natural appearance. Till a proper treatment has been adopted, the venereal pustule keeps constantly forming on the skin for long periods, and thus we commonly see the pustule, the crust, the ulcer, and the depressed and coloured cicatrix all present in the skin at the same time, giving the malady the appearance of a compound skin disease.

In pustular secondary syphilis, then, we have four distinct forms of local mischief—the pustule, the crust, the ulcer, and the depressed and coloured cicatrix, and in the advanced stages of the disease it almost invariably happens that all these conditions are present on the skin at the same time. In many forms of pustular syphilis, particularly the two first, to which I have drawn your attention, the constitutional disturbance is not so great as the extent of the local malady would lead you to expect; thus in the two cases which I have shown you, the general health is little disturbed. But there are other instances in which the constitutional disturbance

is so great as to put the life of the patient in imminent danger; we had an example of this lately in the detached lower men's ward, in a patient suffering from the large single pustules, (syphilitic ecthyma.) This patient was reduced to an extreme degree of weakness, the extremities were œdematous, he suffered from hectic and night sweats, and was altogether in a very precarious condition. Sarsaparilla, broth, opiates, baths, with the iodine of iron, &c., however, were successful in restoring him to good health, and he left the hospital free from any symptoms of syphilis. All the forms of pustular constitutional syphilis are formidable diseases, and indicate a profound and complete contamination of the system by the syphilitic virus. In the second and third forms, the general health suffers more or less, and a fatal termination may ensue, in which a general breaking up of the constitution takes place, preceded by diarrhoea and profuse night perspirations. Happily, however, under a proper treatment, this is not often the case.

Pustular syphilis is formidable again, from the marks and depressions left on the skin, and on the surfaces of the flat bones by the cicatrices of the ulcers to which it gives rise, which may be frequently avoided if the patient is treated early and before the rupture of the pustule; it is commonly the forerunner of, if it be not accompanied by, tubercles and diseases of the bones. Pains in the bones, nodes, and periostoses, commonly complicate pustular syphilis, particularly where the pustules are simple and large, the example already alluded to, and the patient in the detached men's ward illustrate what I have just said on this point. We may next inquire, gentlemen, how such a formidable disease is to be treated, and here it must be quite evident to you from what I have said, and what you have seen of the disease, that its stages are so numerous, its complications and pathology so varied, and the conditions of the general health under which it is met with, so different, that no specific treatment can be in any way applicable to pustular syphilis considered as a mere secondary venereal disease. It must be quite clear that the treatment of the milary or impetigenous pustule in a patient in good health, must totally differ from that we should adopt in a patient suffering from ecthyma, where the patient is weak and the health bad, and yet they are both pustular secondary syphilis.

If a patient be presented to us for treatment, suffering from either the first or second form of pustular syphilis, and the health be good and the disease recent, the following plan of treatment should be followed:—He should first have a smart aperient exhibited, and be placed, not upon a low diet exactly, but upon a diet consisting of cocoa, milk, broth, and farinaceous matters, generally; no beer, wine, spirits, or animal food, if the latter be permitted it should be taken very sparingly. Much difference of opinion exists with regard to diet in secondary syphilis, but on this point it appears to me that the diet, like the medical treatment, must be varied to suit the circumstances of the case. Of one thing I am certain, that should a patient upwards of forty, become tainted with secondary syphilis, and such

patient has been in the habit of constantly living well, a low diet must be adopted with great caution. Age and habit have a vast influence over secondary syphilis, and modify the course and treatment of both very materially. But to return, we take one of the patients in the middle front men's ward as a type of the form of treatment to be adopted when the disease is recent, the health good, and the patient not more than thirty or thirty-five years of age.

1st. An aperient.

2nd. The diet already indicated.

3rd. Decoctions of the woods, with antimonials.

4th. The ordinary vapour or hot bath three times a week. The vapour, however, is far superior to the water-bath. This treatment to be pursued for a week. At the end of that time the plan should be somewhat modified.

The diet should be the same, a little better if the patient feels the change in his habits much. A tenth or twelfth of a grain of the bin-iodide of mercury given as a solution in water, with from three to five grains of the iodine of potassium. The vapour is to be changed for the moist mercurial fume, on the plan I have suggested. This to be used three times a week. If the mercurial plan thus laid down be well and carefully regulated and arranged, no salivation or ulceration of the mouth or any of the more common and evil effects of mercury will be produced. A mere redness, with slight swelling and elevation of the gums is all we shall observe, and this is enough for our purpose.

The bin-iodine of mercury, with the iodide of potass, may be discontinued for two days in every eight or ten, and an aperient again given.

If this plan be carefully pursued, we shall soon perceive a beneficial change in the condition of our patient. In the first place, after two or three days' treatment we perceive that no more pustules appear, that the disposition to their formation is for the time arrested; again, the red or copper coloured ring round the pustules, that are covered with crusts, looks less ovoid, and the eruption looks more dead; after a time the crusts begin to drop off, and we find that in many places, where they formed the covering to ulcers, that these ulcers have healed, and that there is a red cicatrix only, marking the site of the previously existing ulcer. This cicatrix, very commonly depressed more or less in the skin, forms a pit not unlike that left by pustules of small-pox. The crust is the best dressing to the ulcers underneath, under ordinary circumstances, and this is proved by the crusts adhering till the ulcer has healed, under a proper constitutional treatment, and then falling off. If, however, the ulcers are unhealthy, and disposed to spread, we find drops of pus exuding through the crust, or the crust falls, leaving the sore underneath in very various conditions. To these sores various applications may be used. I generally poultice them if foul, for a day or two, then wash them with a little black wash, and cover them with collodion, or the solution of gutta-percha in chloroform, suggested by Dr. Graves, of Dublin. If they secrete much, they may be dusted with starch and calomel; ointments

are generally unsuited to these ulcers, and under ordinary conditions the collodion, or gutta-percha dressing, to defend them from friction and atmospheric influences, answers very well.

This plan should be followed for a month or six weeks, and at the end of that time we shall find that the symptoms of pustular syphilis have disappeared, with the exception, probably, of the red stains left on the site of the ulcers. If they have been deep, it is some time before this redness altogether subsides, perhaps two months, or even three, or more, according to the severity of the attack. Treatment should not be given up, although it should be modified, till all the redness left on the skin has disappeared. If the destruction of parts by the ulceration has been great, the skin is far from presenting its original healthy appearance; it remains puckered, and uneven in places, resembling the appearance of the cicatrices produced by a burn.

In the men's lower detached ward we have a good example of the third form of pustular syphilis, which systematic dermatologists have named "ecthyma." In this patient the constitution has been nearly destroyed by the irritation of the disease. When admitted he presented an illustration of the last stage of syphilitic cachexia. He could not stand, the extremities were oedematous, night perspirations profuse, and pain in the bones of the head and legs very severe. There were seven or eight large secondary ulcers, of foul character, on the head, arms, and legs, which had resulted from the rupture of the pustules, and in two places were pustules recently formed, which offered a good illustration of their commencement. The epidermis was raised by a purulent collection, of the size of a shilling, the covering of which was very thin, the pustule itself surrounded by a deep livid-coloured areola; the skin on which the pustule rested was not indurated.

I gave this patient at first large doses of opium, an admirable anti-syphilitic in such states. I have employed opium very largely in the advanced stages of constitutional syphilitic diseases. Opium has, by a number of authorities, been extolled as a remedy of great value in many forms of secondary syphilis, and its administration by some surgeons has been carried to the extent of twenty or thirty grains a day. Opium is indicated where the health has been broken by mercury and syphilis, and its administration is almost always followed by satisfactory results. It is of especial use where the nights are bad, and the patient emaciated and feeble, where a general irritability—the result of mercury and disease prevails—appears to be wearing the patient out. In such cases opium, in large doses, acts almost magically. In many instances it may be advantageously combined with other remedies, to suit the exigencies of any particular case. I am in the habit of prescribing it combined with guaiacum, with very good results.

Opium, the warm-bath, appropriate dressings to the secondary ulcers produced by the rupture of the pustules, with beef-tea, and decoctions of the woods, are the first remedies to be employed in such states as those

to which I have just alluded. As the patient improves, the vapour-bath must be used, and the iodide of iron given. There may be many other syphilitic symptoms present, with the pustular disease of the skin and its consequences. Pustules are commonly complicated with tubercles, tophi, and almost always in advanced forms, with pains or diseases in the bones. Such states, of course, require modifications in the treatment suited to the exigencies of each particular case.

ON THE

DIAGNOSIS OF CHRONIC OVARIAN TUMOURS.

BY E. J. TILT, M.D.,

Senior Physician to the Farringdon General Dispensary and Lying-in Charity, and to the Paddington Free Dispensary for Diseases of Women and Children.

"Hydrops ovariorum ut plurimum steriles annosaeque mulieres occupat difficilius cognoscitur et vix sine sectio cadavere."—Boerhaave (*Aph.* 1233.)

(1) *Renal Cysts may be mistaken for Ovarian Tumours.*

ENCYSTED cysts of the kidney, containing a fluid which has none of the characteristics of urine are sometimes met with, and Dr. Bright judiciously observes, that perhaps of all errors made in the diagnosis of kidney disease, the most frequent has been to consider the enlarged kidney as an ovarian or an uterine tumour.

Case.—We have seen, says Caseau, (*Bul. de la Société Anatomique*), a renal tumour which gave the abdomen the appearance of a woman six months gone with child. It lifted up the ribs and filled the left side of the abdomen, extending into the iliac fossa. The tumour was fluctuating in part of its extent, and it had displaced the intestines right and left. All who examined the patient, except M. Caillard, thought that the left ovary was the seat of the disorder, but on opening the body, an encephaloid cancer of the kidney was found.

M. Ripault presented to the same Society an acephalo-cystic cyst of the kidney, which had been mistaken for ovarian dropsy; but the most interesting case of renal cyst simulating an ovarian, not only in its general appearance, but even in its termination, is given by Dr. James Johnson in his Review, (Vol. ii.)

Case.—A woman about 30 years of age, complained of considerable pain in the side when pregnant of her third child. She became easier after her delivery, which was not impeded by a tumour, easily felt after her confinement, and supposed to be ovarian, by Dr. Johnson and five other medical men. A few days after delivery the patient was drenched, while in bed, by a milky fluid, which she said was similar to the milky water she had sometimes passed before pregnancy, so the tumour disappeared, but the patient's strength failed and she died. This fluid was by some supposed to have come from the Fallopian tube, by others from the bladder, but a *post-mortem* examination proved that the ovaries and tubes

were perfectly healthy, and that the cyst was found to be an immense bag formed by the capsule of the kidney, prodigiously distended, communicating with the bladder. It contained full three pints of the fluid and had probably contained five or six quarts. The pelvis of the kidney had become sufficiently distended to line the inner surface of the sac, while the glandular substance expanded between the pelvic and capsular tissues, formed papillary bodies which covered the cyst, and secreted the milky fluid. There was no trace of peritoneal inflammation. The milky urine and the invariable exacerbations of pain in the lumbar region, when the urine became scanty or assumed its natural or a higher colour would furnish a help to diagnosis in a similar case. Here the accoucheur was to blame for not having investigated the tumour immediately after parturition.

In the beginning of renal enlargements it would be difficult to fall into this error. The pain, if any, would be referred more to the seat of the kidneys than to the ovarian region, the tumour would be found more or less isolated from the iliac region occupying the upper portion of the abdomen, and descending from it, but when the practitioner only sees the case after the tumour has attained its greatest size, the diagnosis is extremely difficult. The tumour will present the same abdominal appearance—the same fluctuating tumour surrounded by intestines; the general symptoms are the same; the menstrual function is not seriously deranged, and even if an exploratory tapping were made, it would not decide the question. It is true that we may gather presumptive evidence from the previous history of the case, but in the absence of decisive proof, encysted tumours of the kidney are liable to be taken for ovarian dropsy so long as the one disease remains frequent and the other rare.

(2) *A Distended Bladder has been mistaken for an Ovarian Cyst.*

We are ashamed to say, that there are well authenticated instances of this mistake besides the one Dr. Copland mentions having seen, and this shows to what fatal results an unpardonable want of care may lead. By following the precept to empty the bladder before making any very minute investigation of a patient's case, such mistakes may generally be avoided, when the bladder is healthy. It may however be, that the retroverted womb presses so hard upon the neck of the bladder that the free passage of the urine is prevented, and the distended bladder rises like a smooth round tumour from the pelvic region; but then the position of the tumour, and its distinct fluctuation, points out its nature, and when the uterus is replaced by means of the uterine sound, a catheter may be introduced to draw off the contents of the bladder. But the bladder may be pressed upon by a tumour so as to be divided into two equal cavities, as in the following interesting case, related in our work "On Diseases of Menstruation and Ovarian Inflammation," p. 36:—

Case.—A woman, aged forty-five, had been long suffering from some undefined abdominal complaint

before entering La Charitié, on February 15th, 1848. The abdomen was uniformly enlarged, and tender when pressed; there was also retention of urine; and on introducing the catheter the instrument took a perpendicular direction against the pubes, and only a few ounces of urine were voided, though on percussion, the bladder still sounded as if full. The male catheter was then substituted for the female, and Dr. Blanche, with some trouble, and by exercising a moderate degree of force, penetrated into a second portion of the bladder, and evacuated from two to three pints of urine. This operation was daily performed with the same difficulties. All this was esteemed by Dr. Caseau to be the result of an ovarian tumour; in Professor Velpeau's opinion it was caused by an uterine tumour; but Dr. Rayer prudently forebore giving any diagnosis. The patient lingered for several days with increased abdominal pain, fever, and weakness, and then died.

Post-mortem Examination.—We found general peritonitis, with considerable effusion. The bladder was enlarged, and presented traces of chronic inflammation, and a few gangrenous spots; the uterus and ovaries were without adhesion. To explain the peculiarity of the patient's symptoms, we found between the bladder and the rectum a globular tumour, about the size of a cocoa-nut. Its parietes were very thin, firm, and fibrous. It contained a yellow fluid, of the colour and fluidity of ordinary urine. It was this tumour which pressed on the bladder against the pubes, and so divided it into two cavities, that on sounding the woman it was not difficult to penetrate into the smaller cavity, but it required greater force and a longer instrument to enter the second portion. This woman had been carefully examined by some of the most eminent men in Paris, yet the explorations per rectum and per vaginam separately, did not lead to the detection of the tumour, perhaps on account of its uniform elasticity; but had the double touch been put in practice, the tumour would have been detected; and if its detection had taken place before the supervention of general peritonitis, the patient's life might have been prolonged. In reference to this case we may remark, that had the patient fallen into inexperienced hands, force might have been employed in the usual direction of the female urethra, the cyst might have been perforated, and its contents evacuated, and looked upon as urine. One of two things would then have occurred—the inflammation of the cyst, as a consequence of the ingress of urine to its cavity, and ultimate death; or adhesive inflammation might have taken place, and the patient have been cured without the nature of her complaint being ascertained.

If the tumour itself cannot be easily made out, it will be difficult not to be impressed that the bladder is not the principal seat of the disease. By careful manipulations with the male sound, it will be possible to penetrate into the second cavity of the bladder, and if so, by the withdrawal of the urine it contains, we also subtract from the complicated problem the element bladder; if that be not possible, we may attempt, in some cases, to do like Madame Boivin, to force up the tumour. “I

introduced, (says this eminent lady,) a bent instrument, shaped like a spoon, between a tumour and the internal face of the pubis, and then, by pressing from above downwards, and from before towards the back, I was at last able so to compress the tumour as to permit the introduction of the catheter.” Should it be impossible to displace the tumour, we must then be guided by the history of the case,—by the state of the urine, which will be little affected if the bladder is not the principal disease, and the practitioner must wait until the growth of the tumour relieves the bladder from its pernicious interference. If the bladder is in itself diseased, it may give rise to a very pardonable error of diagnosis. Thus we read in Morgagni:—

Case.—A woman, 40 years of age, was much troubled with floodings, leucorrhœa, hypogastric pain, and that a swelling was felt, rising from the pubes to within an inch of the navel. The patient was also subject to vomiting, and to strangury, and was supposed to be afflicted with cancer of the womb. On examination after death the tumour was found to be an enormous bladder, the walls of which were so hypertrophied as to be formed of a hard white substance, as thick as the little finger. Above the pubes this bladder was united to the abdominal walls. Uterine lesions explained the uterine symptoms.

Remarks.—This case is interesting, not only in itself, but as a proof of the gratifying improvement of medical art. Such a case in these days would not be mistaken for cancer of the womb. The speculum would have shown that the womb was not thus affected, the passing of a catheter would have shown the dimensions to which the bladder had attained, the nature of the urine would probably have been shown by chemical tests.

A large abscess developed in the anterior wall of the bladder has, it appeared, (Sepul., sect. 21, obs. 25,) been taken for pregnancy, and might, therefore, be taken for ovarian dropsy, but the modes of examination already alluded to would prevent such a mistake.

(m) *An Ovarian Tumour have been mistaken for a Distended Bladder.*

An interesting case of this has been communicated to us.

Case.—A lady came under Mr. Harvey's care for disease of the middle ear, and consequent meningitis, of which she died, but two or three days previous to her decease a supposed retention of urine took place. As the patient was comatose, no information could be obtained from her, and it was natural to suppose that a regular round tumour, about the size of a child's head, situated in the centre of the hypogastric region, was the distended bladder, but on passing the catheter, no urine was withdrawn, and the tumour remained undiminished. Its appearance was so similar to that of the bladder, that both Mr. Harvey and another practitioner were deceived, and from time to time reintroduced the catheter, but with no better success.

On opening the body, death was explained by the

ordinary lesions of meningitis. The suppression of urine might, perhaps, be accounted for, by a granular state of the kidneys; and the hypogastric tumour was a piliferous ovarian cyst, containing atheromatous matter, with hair, and a fragment of bone, resembling a portion of the maxilla bone, from which arose five teeth. If the patient had not been moribund, we have no doubt that those who attended the case would have required the conviction of its being ovarian, by examining it carefully; as it was, they provided against the retention of urine. The urine, had it passed, would have indicated the granular state of the kidneys.

11, York Street, Portman Square.

[To be continued.]

ON SYPHILIS AND GONORRHOEA.

By W. A. COX, Esq., BATH.

Read at the Quarterly Meeting of the Bath and Bristol Branch, Oct. 7, 1852.

THE question I submit to the consideration of this meeting is,—“Can Syphilis and Gonorrhœa coexist in the same person?”

This, it appears to me, is not a mere abstract and theoretical question, but one of deep importance, because bearing on every-day practice. The more than half a century that has elapsed since John Hunter's death, has not only very much modified our practice in the treatment of venereal disease, but in its experience has shown us that the determination of what is and what is not a true syphilitic sore is not assisted by the existence of such marked characters as that great surgeon appears to have thought. Sores of a character apparently the most innocent will every now and then be followed by well-marked secondary symptoms; so that at last we seem driven to M. Ricord's conclusion, that there is absolutely no sufficient test of what is and what is not a true syphilitic sore, except the production of another sore of a similar character in the same patient by inoculation from the virus of the original; a conclusion which Mr. B. Cooper has also arrived at. (*Medical Gazette*, vol. xliii., p. 996.)

There is no doubt that a surgeon's reputation may be very seriously affected by this difficulty, if not impossibility, of absolute diagnosis. Mr. Lawrence says:—“The first effect of the venereal poison may be an ulcer quite superficial, or a mere excoriation without loss of substance. Many consider that such appearances are not syphilitic. I regard them just as much so as the other forms: they give rise to secondary syphilitic symptoms:” and then he gives a case in a gentleman of “acute syphilitic iritis, of which (he says) the characters were so well marked that I immediately told him he had venereal disease of the eye.” He denied having contracted a venereal affection; but there was a scaly venereal eruption about him, and he acknowledged to a slight excoriation which did not heal completely for a few weeks, and was declared by a

medical man not to be venereal. (*Medical Gazette*, vol. xxi., p. 743.)

Let me take another case:—A young man applies with gonorrhœa, which he says he has had two months. He has also a sore on the prepuce, which is indurated and in a state of phimosis. I do not mean that the sore, but that the prepuce, was indurated;—that kind of induration so well described by Mr. Skey as “soft thickening.” There was, besides, an incipient tumour in the right groin. In this case the opinion entertained by the surgeon is, that the ulceration is syphilitic—that it would lead to secondary symptoms; and, therefore, that it should be treated with mercury. It is so treated, and the sore heals.

By some this has been considered as of great importance in forming a diagnosis; and no doubt it is. But suppose a different case; suppose such a case as the above, complicated with such a state of health as to render the exhibition of mercury hardly admissible, how invaluable would be any means of determining that the ulcer was absolutely not syphilitic. Suppose that such test is to be found in the coexistence of gonorrhœa, how cheerfully should we speak to our patient, and point out to him that, smarting as he might be, under arid urine,—racked as he might be during the still midnight with terrible chordee;—labour as he might, to squeeze some few drops of urine through a strictured urethra—yet, he had this consolation, that as he had gonorrhœa, the sore which accompanied it was innocent and not syphilitic;—that now there was no necessity of loosening his teeth with mercury, whilst we sickened his stomach with copaiba. Nay, we might add, that as gonorrhœa and syphilis could not coexist, he, for the time at least, bore a charmed life; that if, unhappily, he should, whilst having a gonorrhœa, fall again into temptation, under the consequences of which he was then smarting, he might make his mind easy. It would not be necessary, at any rate, to attend the schools of Paris to learn how he might indulge in his amours without danger; for he was safe—he had gonorrhœa; possibly he might increase it, but syphilis he could not contract; and though he might tell us that this sore had appeared some considerable time after the gonorrhœa, and, indeed, after another illicit intercourse into which he had been tempted, we might assure him there was no danger;—syphilis it could not be, and secondary symptoms it would not produce. It might not, indeed, be so easy to determine what was a true syphilitic sore; but about the gonorrhœa there could be no doubt; and where it was, syphilis could not exist. It is only to be feared that such a scientific discovery, presenting us as it does with perfect diagnosis and absolute prophylaxis, might be seized on by the faster portion of our population, and that our Lotharios might be willing to compound for an immunity from syphilis by possessing an unimportant gonorrhœa; and thus our respect for the public morals might compel us to keep to ourselves a fact so dangerous to their purity.

But, is it a fact that syphilis and gonorrhœa cannot coexist? I am not aware of any authority which can be quoted in support of the assertion. So far from its

being a general opinion, the very reverse appears to be universally implied, and to be accepted by writers as a fact of which there is no doubt.

Mr. Lawrence expressly acknowledges it. He says:—"Now we do occasionally find that the two diseases exist together; but this is comparatively rare." (*Lancet*, of March 13th, 1830, p. 810.)

In the reports of the Lock Hospital, as reported in the *Lancet*, of October 25th, 1834, p. 189, will be found cases of syphilis and gonorrhœa coexistent in the same patient.

Dr. Fenwick gives, in the *Medical Gazette*, a report of 943 cases. Of these, 252 were cases of simple gonorrhœa; in 170, sores existed with gonorrhœa; and in 521, sores existed alone. It has occurred to me, in looking over this paper, that the question of the non-coexistence of these two diseases appears never to have entered his mind. He addresses himself not to that question, but to the advantage of giving mercury when such a combination exists.

The only other authority I will draw attention to is Rayer, who, when treating on syphilitic diseases of the skin, speaks of what he calls the simple venereal ulcer, the *venerola vulgaris* of Evans, and the common chancre of several French pathologists. He says they are "the most common of all forms of venereal ulcer;" "they are frequently accompanied with blenorrhœa of the glans, with urethral gonorrhœa, and with phimosis;" and "that he has observed every variety of venereal eruption and venereal growth as consequences of these sores."

But may I not appeal to the experience of every man who has had even limited opportunities of judging whether he has not repeatedly met with gonorrhœa complicated with sores, which in other cases he should have said immediately were syphilitic, and treated as such.

BY OCLUS APERTUS.

Division of the Popliteal Artery and Vein—Contusion of the Popliteal Nerve—Gangrene—Death.

GEORGE LUDLOW, waggoner, aged 36, was admitted into the Cheltenham General Hospital on the evening of May 30th, 1852, under the care of Dr. Eves. He fell as he was jumping from a waggon loaded with a ton of coal, the wheel of which passed over his knee. The accident happened near Tewkesbury, at noon on the 29th. He is said to have lost an enormous quantity of blood. The surgeons who saw him at Tewkesbury thought him too weak to be sent here until the evening of the 30th. When seen at eleven p.m. the following

symptoms were present:—Two small wounds in the anterior aspect of the knee, and a wound, about two inches in length, running obliquely across the popliteal space; leg perfectly cold, and slightly discoloured, the lower two-thirds being devoid of sensibility; patient in a state of extreme exhaustion, but free from hæmorrhage. He was ordered a mixture, containing æther, ammonia, and opium, and to have wine. A hot-water bottle was applied to the foot, and the leg was enveloped in cotton-wool.

31st.—Leg more discoloured, but not so cold; there is slight sensibility in the foot; pulse very feeble, and he is very prostrate. Ordered an egg beat up in brandy, (half an ounce,) three times a day, and as much beef-tea as he can take. On consultation, Mr. Fowler and Dr. Eves thought the patient too depressed to sustain the operation of removal of the limb, conceiving that in all probability it would at once destroy life, it was determined, therefore, to wait and watch if an opportunity for the operation should occur.

June 1st.—Leg quite cold, and he has not the slightest feeling in it; he was delirious nearly all last night, but says he feels stronger to-day; bowels were opened yesterday; pulse 130, very weak. Ordered one pint of porter, in addition to eggs and brandy.

He died on the morning of the 2nd, at seven o'clock.

Autopsy.—Leg in a complete state of gangrene, with large vesications over the foot; deep discolouration on the back of the thigh, extending nearly to the hip; the popliteal artery and vein were both divided; the artery was blocked up by a coagulum an inch and a half in extent, which was rather adherent to its inner coat, the vessels of which coat were minutely injected in the part contiguous to the clot; the divided extremity of the artery was closed by contraction of its walls, the edges of which were gathered in as it were, forming a rounded termination; the vein was blocked by a coagulum about two inches in length, but which was not so adherent to its inner coat as that in the artery; the popliteal nerve was not divided, but the part corresponding to the division of the vessels was altered in appearance, and presented a dark colour, and softened structure: below this for about an inch it looked healthy, and still lower down it was implicated in the common gangrene of the leg.

Observations.—It is quite clear that in this case the only chance of saving the patient's life, if he had been seen soon enough, would have been by removing the limb above the knee. I am unaware what state he was in when first seen by the surgeons on the spot, or what means were used to suppress hæmorrhage. In all probability a surgeon would hesitate to amputate in a case where the external injury appeared so slight, particularly if the bleeding had ceased, considering also that wounds of the popliteal artery have been successfully treated by ligature. It must be recollected, however, that the circumstances of this case differ from those of a punctured wound of the artery; and we may legitimately infer, that a force sufficient to divide the artery, applied as it was in this case, must necessarily greatly

injure the popliteal and peroneal nerves, and in all probability divide the vein. So that in a similar case of a *contused* and lacerated wound in the popliteal space, with excessive hæmorrhage, the diagnosis would be, that the popliteal artery was wounded, seeing that there is no other vessel there which could pour blood so profusely; and if this artery was wounded, it would follow as an almost unavoidable consequence, that the great nerves and veins would be so much injured, that sphacelus would ensue in the limb. From this it may be inferred, that in such a case the only rational treatment would be immediate amputation, if the patient was able to bear it.

The dissection in this case was interesting, as affording an opportunity of seeing the first steps taken by Nature for restraining hæmorrhage from a large vessel; it was seen that the divided extremity of the artery was contracted or gathered in, as it were, at its edges; then, in all probability, syncope supervening, caused the formation of the clot, by enabling the contraction to resist the force of the circulation, diminished in power as it would be by the faintness. The effusion of lymph, preparatory to the final stage of obliteration, appeared to have commenced, as evidenced, by adhesion of the clot to the walls of the artery.

In the treatment of *incised* wounds of the popliteal artery, the plan to be adopted consists in applying a ligature to both ends of the vessel; compression is inefficient and dangerous. Boyer (*Traité des Maladies Chirurgicales*, p. 286,) relates a case in which a young man received a wound on the external part of the knee-joint, by means of large-pointed scissors used by harness makers; the instrument penetrated between the femur and the tendon of the biceps muscle, and wounded the popliteal artery. Considerable hæmorrhage followed, which was arrested by pressure. At the end of some days, after a hasty movement, the bleeding recommenced, and was restrained by a stronger compression. A third hæmorrhage occurred, and was arrested by a bandage applied still more tightly. The limb now swelled enormously, and became mottled, livid, and cold. Boyer being called in consultation, (the leg being already gangrenous as far as the knee,) removed the limb, and cured the patient. On dissection the artery was found opened on its outer aspect to the extent of two lines.

Probable Fracture of the Ribs, with Emphysema and Traumatic Hæmothorax.

WILLIAM HAMPTON, aged 38, was admitted into the Cheltenham General Hospital, under Dr. Eves, April 30th, 1852, a cart wheel having passed over the lower part of the thorax, the cart itself, according to his own statements, weighing $9\frac{1}{2}$ cwt., and being at the time loaded with 18 cwt. of coal. He states, moreover, that the wheel passed quite over his body. At night he was in a state of alarming exhaustion.

Present condition.—May 2nd.—The right side is much bruised, and there exists an emphysematous condition, extending from the seat of the contusion, up

to within a short distance of the clavicle; there is great pain on pressure, both over the right side of the chest and abdomen; his tongue is covered with a whitish fur; the face is flushed; pulse 78. On the morning after the accident he was unable to pass his water, which was, accordingly, drawn off with a catheter, since which he has suffered, to a certain extent, from hæmaturia.—R. Ant. Pot. Tart., gr. j.; Liqueur Opii Sed., dr. ss.; Mist. Camph., oz. vj. M. Sumat. oz. ss., secundis horis. He has already taken two aperient pills, which have acted on the bowels.

3rd.—General symptoms much the same; tongue somewhat browner than yesterday; pulse 84; respirations short, shallow, and laboured, 40 in the minute; is unable to take a deep breath without causing great pain about the 7th and 8th ribs.

Physical Signs.—Emphysema much diminished; complete dulness and resistance to the finger on percussion over the lower and front part of the chest, extending upwards to within an inch of the nipple; movement of expansion less on this side. There is still much pain on pressure. In the upper part of the right lung the respiration is short and jerking. Over the sixth, seventh, and eighth ribs the murmurs are barely audible; but there may be detected a few cracklings (probable false pleural rœchi), occurring just under the ear. On the left side there exists a compensatory respiration.—R. Antim. Potass. Tart., gr. ij.; Aquæ, oz. viij. M. Capt. oz. ss. secundis horis. He was likewise ordered twelve leeches to the affected side.

May 4th.—Complains less of pain; the breathing is still difficult but less frequent; the crackling has disappeared; physical signs otherwise unchanged. The leeches bled freely. Bowels open; tongue dry and furred; pulse 84. To take the mixture every three hours.

May 5th.—There is still much tenderness over the lower and anterior part of the right side, extending backwards. Respiration now audible over the seat of injury. The dulness does not extend quite so high as when first examined.—R. Hydrarg. c. Cretâ, gr. iij.; Pulv. Ipecac. Co., gr. v. M. et fiat pulv. horâ somni sumendus.

8th.—Pain on pressure much diminished. Pulse 72.

10th.—Improving. To take the mixture three times a day only, and to continue the powders.

13th.—Breathing still painful and laborious. Extent of dulness on percussion but little altered. To omit the mixture but continue powders. Ordered Empl. Lyttæ regioni hypochond. dextræ.

15th.—Much the same. To take the powders night and morning.

17th.—Appetite bad; tongue cleaning. No alteration in the dulness on percussion. The side was ordered to be painted with Tintura Iodini Co.

25th.—Complains of Pain during inspiration in the lower and posterior part of the left side. To take a powder at night only.

31st.—The dulness is now diminishing in point of extent. General health improving.

June 3rd.—Still improving.

7th.—Feels much better; gums sore. Cont. Pulv.

12th.—Says he is getting stronger every day.

19th.—Is so much improved that he thinks of going out of the hospital. Previous to his so doing his chest was examined. The dullness formerly noticed had disappeared in front, but the right lower back was still less resonant than the left; the respiratory murmurs were now audible, though more feeble, on the right than on the left side, especially at the lower and back part of the lungs; a deep inspiration produced a kind of crumpling sound over the seat of the injury. Expansion the same on both sides. General health good.

Remarks.—It is not improbable that in this case there occurred a laceration and rupture of one or more vessels, giving rise to an effusion of blood into the cavity of the pleura, and thus producing the physical phenomena mentioned as having been detected in the neighbourhood of the injured part. It is not likely that the effusion could have been very considerable, since little more than seven weeks were necessary to allow of the chest recovering its sonority and healthy play. Fortunately there appears to have been no inflammatory complication, as might not unreasonably have been anticipated under the circumstances, and with the exception of the alarming collapse which took place on the night of his admission, and which was in all probability the result of the escape of the blood into the pleural cavity, the recovery took place without any untoward symptom.

Proceedings of Societies.

BATH AND BRISTOL BRANCH.

THE quarterly meeting of the Bath and Bristol Branch of the Provincial Medical and Surgical Association was held at the Royal Western Hotel, Bristol, October 7th, 1852, at half-past seven, P.M.

There were present from the Bath District, George Norman, Esq., President, in the chair; Messrs Bailey, Barrett, Bush, Bartrum, James Crang, Cox, Davies, M.D., Edwards, King, Mason, Parsons, Skeate, John Soden, Stone, Thurnam, M.D., and Wilkins. From the Bristol District, Messrs. Budd, M.D., Burroughs, Collins, Coe, Colthurst, Cross, Estlin, Godfrey, Green, Lancaster, Leonard, Mayor, Morgan, Nield, O'Brien, Prichard, Rogers, M.D., Sawyer, Smerdon, J. G. Swayne, M.D., S. H. Swayne, Symonds, M.D., Swete, Wilson, and Woodforde.

MR. BARTRUM read the minutes of the last quarterly meeting at Bath, which were confirmed.

MR. WILSON was almost afraid that he should be out of form in doing so, yet requested permission to make a few observations explaining the cause of his absence at the annual meeting, when the question of the life insurance fee was brought forward, and expressing his regret at the form in which the resolution was ultimately passed.

DR. W. DAVIES read a case of "Abscess of the Right Ovary, terminating in Rupture into the Peritoneum, and Death from Acute Peritonitis."

MR. NORMAN referred to a case at present under his care, of a young woman who had a small tumour in the lower part of her abdomen, and who, upon using slight pressure with her own hand, felt something give way. This was followed by inflammatory symptoms, which were subdued, and the patient was doing well.

MR. JOHN BARRETT enquired of Dr. Davies, whether the history of his patient's case before admission to the hospital had been that of active symptoms, as he conceived this would greatly have assisted the diagnosis. He quoted a case of M. Dupuytren's, where rupture of the bladder had not been followed by death for seven days, though the urine had escaped into the cavity of the peritoneum, a receptacle being formed for it by adhesions.

DR. BUDD mentioned a "Case of Peritonitis," arising, he believed, from rupture of the ovary, but which he hoped would terminate favourably. He more particularly noticed the great tolerance of very large doses of opiates in these cases. He also adverted to the remarkable coincidence of two cases of peritonitis occurring on two consecutive days in a father and daughter, both of them arising from ulceration of the small intestines.

MR. PRICHARD read his paper "On Extraneous Bodies removed from the Eye," and exhibited several beautiful specimens microscopically.

MR. JOHN SODEN remarked that a blunt curette was acknowledged by all to be the most convenient instrument for removing extraneous objects from the eye; nevertheless he had found a piece of quill cut into the form of a pen, but without a slit, so exceedingly useful that he thought it well to mention it.

MR. NIELD narrated a case of "Inflammation of the Eye" where there was no apparent cause, nor could any extraneous body be discovered. In consequence of its long continuance, Mr. Estlin was consulted, and found upon everting the upper eyelid very fully, a small elevation of the mucous membrane, consisting of caseous matter, arising, as was suggested, from hardened deposit in the highest follicle or chain of meibomian glands.

MR. GODFREY, having observed on Mr. Pritchard's third case, where vision was not perfect without the use of the muscles of the removed eye, suggested that it might be referred to the consensual action of muscles of the eyeballs; for instance, if one eyeball acted, might not the other act in accordance, and so the iris of the unaffected eye act as though under the influence of direct light?

MR. PRICHARD answered, that could not be, as the eyeball was wholly removed, leaving the stumps of the muscles only.

MR. BARRETT referred to the difficulty he had found in determining whether there was a portion of iron embedded in the cornea, or whether it was only the stain left by it.

MR. PRICHARD remarked, that if the epithelium only were scraped off in the removal of the imbedded mate-

rial, no speck could result; whereas, if any of the layers of the cornea were injured, it would be otherwise.

Mr. ESTLIN recommended the use of the magnifying glass, and more especially noninterference, where the surgeon is uncertain of the existence of a foreign body as the exciting cause of inflammation.

Dr. BUDD called attention to the beautiful physiological fact noticed by Mr. Prichard, with regard to the effect of light upon the fifth pair of nerves.

Mr. PARSONS described the mischief often produced in country districts by small portions of the beard of barley being blown into the eye, it being toothed at the edges, and consequently requiring to be removed by a forceps in the same direction as it was originally driven.

Mr. LANCASTER asked if the rings now exhibited were not the oxyde of iron, the centre being washed away.

The PRESIDENT then called on Mr. Cox for his paper on the coexistence of gonorrhoea and syphilis, first asking him if it referred simply to the subjects mentioned in the notice paper, without in any way touching upon a matter that had been lately of public notoriety.

Mr. Cox, having answered that it was so, proceeded with his paper. (See page 557.)

On its conclusion, the most breathless silence being observed, the PRESIDENT remarked that there was nothing more promised, but if any member had anything which he would wish to bring forward they would be happy to hear it.

Mr. JOHN BARRETT then mentioned a case which he had lately examined, of an infant exposed, and in which he had employed the test proposed by Mr. Bloxam many years ago, of opening the cavity of the chest whilst the head was under water, and observing whether air bubbles then escaped from the mouth: if they did the conclusion was, that the child's lungs had received air, not by artificial, but by natural inflation. In this case no air-bubbles escaped; still the lungs floated, with the heart, &c., as did portions of them; but when crushed in a cloth these portions sank; the lung had also a foetal colour. He concluded, therefore, that respiration had only very partially taken place. The principle on which Mr. Bloxam's test rested was, that after natural inflation there would be a tendency in the lungs to contract, and therefore partially to expel its contained air on opening of the chest, but that this would not be the case after artificial inflation.

Mr. KING, referring to the frequency of child-dropping, remarked that it was a subject of great importance, and medical men ought not to forget that the foetus often breathed in vagina, consequently that the child might breathe so as partially to inflate the lungs, and yet be really stillborn. He noticed it as a point which should never be forgotten in courts of justice.

Mr. JOHN BARRETT observed, the question generally put to the medical witness was, was the child really fully born, and has it naturally respired, and, if after the child has been born had any endeavour been made

to inflate the lungs which would be an endeavour to save the child although the birth may have been subsequently concealed. The child may often cry *in transitu*, but in that case the colour of the lungs would be foetal, and not of full inspiration.

Mr. NORMAN considered that a medical man in a witness-box is bound to state all the facts of the case, and proceeded to illustrate this by describing the course he had pursued when, as a very young man, he was examined by Sir Vicary Gibbs. He stated that the child lately examined had breathed, but at the same time he was bound to explain the fact that children may breathe and yet die shortly afterwards without any criminality on the part of the mother.

Mr. GREEN, with pain, observed the tendency in many individuals to make all such cases criminal, because there was no doubt that stillborn children often gave a feeble moan and a slight struggle, which, unless further assistance was given were followed by death. He believed that the lungs might be partially inflated, and yet there might be no criminality. He had seen the head of a child opened, where yet it subsequently breathed, and the lungs were somewhat inflated. In such a case much difficulty might occur were the question to be brought into a court of justice.

Mr. NIELD referred to the possibility of a child being born alive, and yet being suffocated under the bed-clothes, or by its face lying in the fluids.

Mr. NORMAN saw a case of turning, where the arm had been down some time. The head was a long time coming down. The child breathed at long intervals, fifteen or twenty times, yet it died. In such case the lungs were inflated, yet the child died from want of power to recover.

Mr. MASON mentioned a case recently occurring to himself, of a child breathing as it was passing from the vagina, yet being strangled by the chord looped round its neck, and being tightened during the act of expulsion. The child subsequently recovered.

Mr. LANCASTER then exhibited a specimen of diseased bladder, with enlarged prostate, which he considered of a scirrhus character. In describing the case he referred to its previous history, and the impression that the previous medical attendant had passed an instrument under the supposition that there was a stone.

Mr. WILSON had attended the case, and introduced the catheter without the slightest idea that stone existed, having only the belief that there was an enlarged prostate, such as frequently exist in old men.

Mr. NORMAN could not discover anything more than an enlarged prostate; no scirrhus.

Mr. NIELD had found in some cases of enlarged prostate with irritable bladder and muco-purulent secretions, very great benefit to arise from the injection of a solution of nitrate of silver, one grain and a half to the ounce, the urine becoming quite clear under the use of the injection.

CREWKERNE AND YEOVIL DISTRICT MEDICAL ASSOCIATION.

THE fourth general meeting of the members of this useful and prospering Society was held at Martock, October 7th. Letters apologising for absence were read from Dr. Woodforde, Taunton; Dr. Sydenham, Yeovil; Dr. Pope, Somerton; Mr. Crouch, Bruton; Mr. Valentine, Somerton, &c., &c.

The alterations made in the Draft of the new Medical Reform Bill, published in the *Journal* of May 12th, were read. The members considered that there are some clauses which may be greatly improved, and confirmed the resolutions of the last meeting, published in the same number of the *Journal*.

A very interesting "Case of Strangulated Hernia" was brought forward by Mr. HENRY NORRIS (and is sent for publication). Much discussion ensued on the various modes of relief and methods of operation, and from several cases brought forward the members considered that in this part of the country the results of operations are highly favourable, a fatal termination occurring almost entirely in those cases where recourse to the knife has been too long delayed.

Mr. HUGH NORRIS communicated a case in which pleuro-pericarditis *instantaneously* came on without previous illness or exposure, and early prostration terminated fatally on the 7th day, an autopsy revealing a cretaceous deposit of the size of a large walnut surrounding the right bronchus and pressing on the pulmonary artery, the substance being in the *pulmonary texture*.

The subject of *placenta prævia* caused much discussion, and elicited many illustrations of success in practice from early recourse to evacuation of the uterus, the method of previously detaching the placenta finding little advocacy.

Some medico-legal cases were discussed, the members deriving much information from the medical Coroner for West Somerset, who was one of the visitors.

The HONORARY SECRETARY urged the necessity of a good example being set by medical gentlemen in subscribing to the support of the new Benevolent College.

It was resolved that the next meeting of the Society be held at Crewkerne.

Correspondence.

ON BENEVOLENT AND PROVIDENT SOCIETIES.*

THIS most important feature of the operations of the Medical Benevolent Fund deserves a little further consideration. It has been proposed that some of the local Provident Medical Funds should invest a certain portion of their accumulated resources in the Medical

Benevolent College, and thereby acquire an equivalent right to present to the advantages of that College, applicants from their own members in their own district. It is, however, manifest, that in all those provident institutions, *all the members have a vested interest*, and that the governing bodies of such provident institutions *cannot so invest their capital, without the consent first had and obtained, of all the representatives of those vested interests*. And then, what good has been obtained? Say, a *presentation* to a certain charity. But then these presentations, to prevent injustice to other *direct members of such charity*, must be thrown open to the election of the subscribers generally. At least so it appears to me. These boons then, are to be obtained by the votes of the *majority of the subscribers*; and like other similar institutions, the same means must be resorted to to obtain a majority of such subscribers' votes. Hence the necessity, as in other cases, for an active canvas, and perhaps a repetition of such canvas, on various successive elections, and for a large outlay in cards, postages, letters, &c., &c.; hence the *necessity* for the purchase of votes; and hence the final triumph of him or her who has the largest number of wealthy and active friends, who will come forward to secure the success of their candidate by their purse and their influence; and hence the success of the most *wealthy*. But by the supposition it is not the *wealthy* but the *poor*, who are to be the recipients of these boons, and therefore making money value a test of the fitness of the candidates, is an essential departure from the principle of benevolence. Yet such must inevitably be the case; and the College thus peopled, and thus based upon a false principle, will soon become the arena for the fostering influence of patronage, and the sickly brood of its blighted progeny—hatched under its fostering wing, and collected together by the trading and trickery which attaches to these elective feats, the object of which is to secure success by means however unscrupulous.

How much better is it that the poor destitute candidate should be selected by the Committee of the Benevolent Fund,—selected *on account of poverty and destitution*, and *presented* to an annuity without canvas, and where that annuity can be held with all the sanctity of *home* comforts. I know it may be said that this confines the choice of the annuitant to the *friends* of the Committee. In plain and practical truth it does not; and the cases selected must be those of the most destitute; and I confess myself monarchical enough to prefer the government of the few who are responsible, to that of the many who are irresponsible. But even admitting that the canvass of the many *subscribers* is exchanged for a similar canvas of the few Committee, a great point has been gained in superseding the expense of some thousand applications, which is so distasteful to the educated mind, so degrading to the moral sensibilities, and which places the preponderance of interest in a money test.

Far be it from me, Mr. Editor, to find fault with any of the proceedings of the Medical Benevolent College. But when we are called upon to support any charitable purpose, it becomes us to inquire what scheme can be carried into effect with the least amount of injury, and with the greatest amount of good, to the large professional family—remarkable as it especially is, for its

* Concluded from page 537.

pride as well as its poverty, and whose feelings in their misery, should be held most sacred.

After all, when the annuity has been obtained by influence and wealth, what is the result? True, there is a home obtained, under the paralysing conviction of the doubtful means by which it has been procured; the unsuccessful candidates with small purses are grievously annoyed; the successful ones find in their little homes, anything but the asylum of peace. The motley progeny of passions, called into being by the provocatives of society, prey upon its constitution; the seeds of discord are widely sown, and rapidly vegetate, and under their lurid influence, the wretched annuitant finds that he has left peace behind him, and that for the sake of a home enclosed by four walls, he has abandoned all the real comforts of the sunset of life's history. How infinitely to be preferred is the annuity which can be enjoyed in the bosom of the family and the scanty sum which ministers to the daily wants, to the more affluent pittance with diminished self respect.

In this review, Mr. Editor, I have fixed upon the annuity scheme for discussion; but I must point out to you that there are many emergencies of life which cannot be provided for by the Benevolent College, and which cannot be superseded by its means of relief; and that these can only be met by a fund whose object is to relieve such emergencies. I will only select a very few of the cases of the last Committee, viz. :—

I. The widow of a medical man, and the daughter of a clergyman once in great affluence, and reduced to beggary by the knavery of a trustee, by whom family resources were wasted,—yet too young for an annuity, and capable of earning her own living, if temporarily aided through existing difficulties.

II. A paralytic old lady, supported by her children, but now requiring so much attention as to interfere with the kind aid of these children, by destroying their night's rest, and so sapping the powers of working for their aged parent.

III. A medical practitioner of the highest respectability, suddenly becoming insane, and, consequently, a burden to his family, instead of its support and mainstay.

IV. A widow, seeking a home for herself as companion to a lady, but now long out of employment, and reduced to the most distressing straits, yet requiring only temporary aid, to be again restored to active duties and her own self-dependence.

V. A lady with four children, the widow of a medical man, who, from adverse circumstances, was an assistant only, and who, with his family, had been struggling onwards through great difficulties, and whose life fell a victim at last, in one week, to typhus fever in one of our public hospitals. She is yet quite young, and if now aided for a time, may be able to obtain her own livelihood, and provide, at least in part, for her young children, the last of whom is an infant of a few weeks old.

These are only excerpts from the minutes of the last Committee meeting, and are only paralleled, if not exceeded by every Committee meeting. I say not, Mr. Editor, that we are perfect;—I say not that we *never* do any harm;—I say not that we are *never* imposed upon;—I say not that we *never* relieve an unworthy object. He who waits to be charitable till he is quite

sure that his charity will *never* be abused, must be contented to become a drone in the great hive of man's industry, and to give up the pleasure of doing good, as well as the duty of *doing* all the good he can to his fellow-creatures.

But I do say that cases such as these are *unrelieved* and *unrelievable* by any other institution than the Benevolent Fund; and that till some other fund has been established, for the relief of these cases of temporary distress, the Medical Benevolent Fund *deserves* and *demand*s our sympathy and our unabated energies, to enlarge its resources and extend its influence and usefulness. Perhaps I may be permitted to say, as a motive to such sympathy, that so crippled are our resources at present, that, but for the advances of our good-natured Treasurer, the cases above-mentioned must have gone *unrelieved*. And here, I make my appeal to each individual who peruses these pages: will you in very deed, suffer such a slur to be cast upon our profession—as, that they refused to listen to these cases of distress, because they did not make a public appeal to their charity in the newspapers; because, in the modesty and retiringness of real sorrow, these cases were known only to a few friends, whose pitying eye beheld their wretchedness? Shall it be said that we have forgotten the argument of the Divine Founder of our faith:—"Inasmuch as you have done it to one of the least of these my brethren, you have done it unto me?" Shall it be said, that the sympathies of the professional family are less than those of the selfish world around us, and that we will allow others to do the work which it is our duty to do? O! suffer not such a veritable sarcasm to be cast in our teeth,—that we appear to sympathise with *every* sorrow except that of our own family circle; but that to this we turn a deaf ear, and are content to say:—"Be ye filled, and be ye clothed," and yet that we give them not the things which are requisite for their immediate wants.

And now Mr. Editor, what are the conclusions to which we should arrive, from a review of the preceding discussion? I think they are something like the following:—

1. There is a vast amount of misery afloat in the profession, which may be guarded against, and perhaps almost superseded, by habits of prudence, of thrift, and of forethought.

2. Therefore it should be our grand, and our first object, to encourage these habits, which may greatly take the place of charitable institutions. Hence, life-insurance, in all its various forms and modifications, adapted to the exigencies of each particular case, should in every instance be encouraged. To insure against the uncertain accident of fire, and not to insure against the certain and inevitable evil of death, is a folly almost inconceivable, did not daily experience convince us of the contrary. Let each husband and father ask himself,—Have I done my duty towards those most dear to me, if I have left them unprovided for? And let no consideration of present inconvenience withdraw the attention from this *first* duty, till at any cost it has been accomplished.

3. But there is still a vast amount of misery which no prudence can obviate, no foresight can anticipate, no forethought can prevent.

4. This amount of misery is only to be met by palliative means,—by remedies which will alleviate the evil, by the dole of charity; by that sympathy which is willing, at the expense of its own self-denial, to minister to a brother's woe, and to extend the hand of charity to depths of sorrow and of suffering which no other hand can reach. "If there be among you a poor man, one of thy brethren, within any of thy gates, thou shalt not harden thy heart, nor shut thy hand from thy poor brother, but thou shalt open thy hand wide unto him, and shalt surely lend him sufficient for his need, in that which he wanteth."—*Deuteronomy*, ch. xv., v. 78.

5. There are various plans afloat calculated to relieve these several forms of wretchedness, and it is our duty, if we are able, to *support them all*.

6. But in the event of our not possessing the means of support to *all*, it becomes us to consider which has the largest claim upon our sympathy; and in order to determine this, we must distribute our patronage according to our individual wants and capacities.

7. I would say to every one entering the profession, and hesitating about marrying,—deny thyself: do not think of marrying till you can *keep a wife*, and have good reason to believe that you can minister to the wants of a family, by the extension of your practice, and by that increasing energy, and augmented personal sacrifices, which will keep your head above water, though placed in trying circumstances.

8. On no account marry till you have insured your life, at least for a sum which will secure your widow from indigence and destitution; and on no account omit to enlarge this insurance with the birth of every child, either by increasing the sum insured upon your own life, or by an annuity upon your widow, or by endowment upon your children. True, you will sometimes find it very difficult to put by the amount of the yearly premium; but never mind, the great object before you is worth a struggle—is worthy of many a self-denying sacrifice, and will afford an amount of satisfaction to your own mind which will far more than counterbalance the weight of such sacrifice.

9. Do not be tempted to attach yourself to any institution which boasts great things, but whose principles are unsound, as for instance Mr. Daniel's extinct Annuity Fund. Had this been generally adopted, it never could have realised what its projector fondly hoped; and although it promised, for a guinea a year, an annuity for widows of a large amount, yet it was clear to every thinking person, that an annuity of even £20 a year can only be produced by the investment in permanent securities of many hundreds of pounds. This fund had no foundation in truth; and though it was subsequently much improved, yet it is now dead, and need not be resuscitated.

10. But there are various local provident funds, which appear to flourish, which promise largely, and which have accumulated large capital. I would only say—**BEWARE**: money cannot be self-created; therefore consider first what such societies promise, and who are the directors and trustees, and what is the state of their funds, and the amount of their liabilities; estimating the probable duration of life, and considering, not simply what are the present drains upon their funds, but what they would be in the event of its becoming

general, that all young men should attach themselves to such funds, and therefore, that a certain number of widows would, in the ordinary calculation of the value of human life, become claimants upon its resources.

11. Do not hastily belong to these funds, for they may be sound *now* with a large number of honorary members, yet would cease to be so on the accession of a considerable number of ordinary members, which would be the case whenever this system of providence shall become general.

12. The provision against sickness and other similar contingencies, is surrounded with many difficulties, chiefly from the absence of sufficient data upon which to ground calculations, but it has hitherto been a failure, and now that the British Medical Fund is extinct, has no secure nucleua whence its benefits could be dispensed.

13. But all the ordinary contingencies of life *may* be, and that in a very easy way, provided against by means of the various life-insurance societies, and especially our own, the Medical, Legal, and General Life-Assurance Company.

14. And now, having taken all possible precaution to escape from the avoidable and inevitable difficulties of life, and for the demands made upon your purse by your own family, it becomes you duly to consider how far, in the days of your own prosperity, you can contribute towards the relief of your less fortunate brethren, how far you can fulfil the great aim of man's life—to live for others as well as for himself.

15. And here the Medical Benevolent College will present itself to your notice. To its funds many have contributed, from motives of the purest charity, and many from interested motives, and especially from the expectation that they should secure a good education for their children at a small cost.

16. Man's motives are seldom, if ever, perfectly single, and I do not know that we can reasonably complain of their complexity, when they are so pure as in the past instance; but be cautious, the Benevolent College, though it has a name, has as yet no local habitation, and its advantages are all hypothetical—they have not yet been proved. Nevertheless we wish the experiment every success, and if you are able, by all means support its scheme, though as yet untried: it is in good hands, and everything will be done for it, which zeal, industry, untiring activity, and unimpeached good principle can effect.

17. And if it should by-and-by appear that this magnificent project must be reduced to something more simple and educational, even the revival of Mr. Martin's extinct plan for a professional school; still a great boon will be afforded to our brethren, and an important object will be accomplished, in obtaining for patients a better educated race of young medical men.

18. Yet, always remember, that however provident you may have been yourself;—however you may have insured your own life;—however you may have purchased an annuity for your widow, or a deferred annuity for yourself;—however you may have made a provision against old age and infirmity, or endowed your children, and provided for apprentice premiums, or college expenses, or any other expense contingent upon their first setting off in life; yet all this has been

purely selfish, and you have yet a duty to perform—a duty towards others.

19. For it has been shown, that there is an amount of distress in the professional family which cannot be provided for, which no prudence can foresee, no diligence can forestal; there are casualties which nothing but the hand of charity can relieve; and therefore, whilst you are thinking of yourself, and of those immediately dependent upon you, you have other claims; and as a man, and as a Christian—as composing part of the great social family, and as hoping to form part of the still greater family in Heaven, where “the wicked cease from troubling, and the weary are at rest,” you have claims upon your regards and upon your purse, which nought can supersede, and which can only be met by *self-denial*.

20. Remember, there is no charity in that which costs you nothing, and that that is the only real benevolence which costs you the abandonment of some pleasure, or the giving up of some luxury, or the retrenchment of some apparent necessary, in order to assuage the cry, and secure the blessing of him “who is ready to perish.”

21. And here “the Medical Benevolent Fund” steps in as the almoner of your charity. It promises to be the depository of your still hard-earned savings, to watch over their distribution, to give them out to those who are perishing from hunger and destitution, and to save them from starving till brighter days shall dawn upon them. Also it promises to invest the whole of its donations, without any deduction, and from the capital so accumulated, to expend its *income* in granting annuities to the aged and the widow,—to the blind or the helpless,—to the hopelessly paralysed, or the maniac; to those, in fact, who have no relief from other sources, and who can enjoy this little income *at home*. And these annuities are sure, for they are derived from the income of invested capital, and when once given, they are unalterable, and regularly paid every half-year.

22. These are not high-sounding advantages, but they are facts: they are realities—and they are facts and realities which call upon you for support.

23. And O! if there be one motive of pure charity in your bosom;—if your heart throb with sympathy at the recital of another’s woe;—if you are desirous of doing all the good you can in the world, and of living in the memory of the wretched to bless you;—if you would live here in expectation of a joyful hereafter;—if you would humbly imitate the Saviour of mankind, and spend your days in His service, and ascribe the glory of all that you are enabled to do to Him who has given you the power and the will to go about doing good, O! forget not the claims of the Benevolent Fund!!

W. NEWNHAM,

Farnham, Sept. 22, 1852.

Treasurer.

ON THE RELATIVE VALUE OF MATERNAL AND FETAL LIFE.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—I venture, with great respect, to protest against the opinion embodied in the following passage, extracted from your review of Professor Murphy’s recent work,

“On the Principles and Practice of Midwifery”:—
“This view” (i. e., the believing that the life of the child is not to be considered for a moment when weighed against the mother’s,) “is held through all the lectures to an extent which we think scarcely justifiable. We have no right to hold the scales; but our office is to heal all, whether young or old.” No right to hold the scales? Who *is* to hold the scales?—who *is* to decide which way the balance should incline? In other words, who *is* to exercise his discretion and judgment as to the comparative worth of adult and infant life in each particular case where the life of the one involves the destruction of the other, and *vice versa*, if the medical practitioner, upon whom is cast so much responsibility, is not? It is an unphilosophical style of argument, originating in a morbid and false sentiment, which can lead any man to argue upon the sanctity of infant life, as an *abstract* fact. And we have no business to make it an abstract matter until we are fully assured, as far as our diagnostic powers will permit us, of the safety of that more precious life from which alone the infantine one springs. It ought to be considered *entirely* as a thing of *comparison* and *relation*. Who shall venture to affirm that the life of the mother is not infinitely more valuable than that of the recently-born, or about-to-be-born, child? Who shall be bold enough to maintain that a childless, is more desolate than a widowed, home? Who shall say that each being just struggling into life is about to be heir to so much happiness—to be participator in so little sorrow, that efforts are to be made to fan the incipient flame, at the risk of the more important being, upon whose prolonged existence so many may be dependent? There is no more distressing sight in nature than that of an infant whose life has been seured at the sacrifice of its mother’s. It is the most harrowing of all spectacles; for it tells, perchance, of many motherless children, and of a remaining parent, now desolate and alone! It is painful to reflect how many women might have been spared to us if they had sooner received instrumental or manual aid; and the day will come, I hope, when it will be held to be as unsound to attempt to preserve an infant, when such preservation involves maternal risk, as it now is to postpone the operation for a strangulated hernia (which has been done in thousands of cases), in the hope of some relief by natural means, until the bowel is partially or completely disorganised. And this can only be effected by that true philosophy which teaches us that individual life becomes more sacred in proportion to the dependence of others upon it. Upon this principle, carried out of the domestic channel, is England now mourning for a Wellington and a Peel. If *one* medical man will admit (as I do) that he has seen, in one of the largest lying-in hospitals in the United Kingdom, the lives of several mothers sacrificed, and admitted to be sacrificed by those who did it, just for the *chance* of preserving a foetal life, what could not the entire voice of the profession declare?

For myself, I rejoice at the view which Professor Murphy takes of this important subject. Under his auspices, and those of other distinguished accoucheurs, we shall come in our day (so fraught with progress and with change) to appreciate and act upon that true and reasonable system, which teaches us that infantine is

not to be put in the same scale with adult and maternal life, as though they were of one and the same importance; but rather that the former is a miserable little speck in the great and densely-populated arena of humanity, when compared with the latter, already bound to the world by so many and such sacred ties.

I should not have ventured, Sir, to impugn any opinion which you have expressed in your review of a work presented to your notice, had I not felt that a very important principle was involved in the passage quoted at the beginning of this letter.

I am, Sir,

Your obedient Servant,

EDGAR SHEPPARD,

M.R.C.S. & L.S.A.

Enfield, October 15, 1852.

THE ACID TREATMENT OF DIARRHŒA.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Having read with interest Mr. Sheppard's account of patients treated for diarrhœa by sulphuric acid, I followed the method of prescription detailed by that gentleman in your number of the 15th of Sept., with great success, in several cases. I find it applicable to persons of all ages; and in one case, that of a man about fifty years of age, the chalk and catechu mixture had entirely failed before I gave the acid. In another, a little child between two and three years old was relieved in a day from a profuse diarrhœa, with urgent gastric irritation. It appears to check both purging and vomiting more speedily than any other medicine I have yet administered, *without* the addition of opium, except in cases where there is considerable pain. I have always permitted free libations of cold water, which allayed the tormenting thirst, and tended to compose the patient, whilst I have regulated the doses of acid according to Mr. Sheppard's prescriptions, and adapted them to the age of the patient.

There is one point of interest worthy of notice in connection with my experience of this mode of treatment, that, unlike the results of our ordinary astringent prescriptions, when successful, there is no tendency left in the patient to the opposite extreme of costiveness, so frequently produced by chalk, catechu, &c.

I take this opportunity of thanking Mr. Sheppard, with whom I am not personally acquainted, for the valuable hints his paper has afforded me; and

I remain, Sir, your obedient Servant,

JOHN JAMES MITCHELL, L.S.A.,

Surgeon to the Western Dispensary of Bath.

17, Gay Street, Bath, Oct. 19, 1852.

BLISTERS IN GLEET.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In your number of the 1st of September you say, in reference to my proposal for blistering in gleet,—

“But it is so seldom that our patients would like the confinement necessary, that we can scarcely expect the plan, however good, will be extensively followed.”

But, Sir, what is his confinement? I know of none sufficient to deter a patient who really wishes to be cured of gleet. I have blistered many patients who have never laid up an hour, and many more who have applied the blister on Saturday night and gone to business on the Monday morning; sore, it is true, but well able to move about, and attend to business.

Where a patient has unlimited control over his time, it is no great matter whether or not he remains at home till the vesication is healed; but the man of business may rest assured that he need never lose a day by using a blister in this way.

I have the honour to remain, Sir,

Yours obediently,

JOHN L. MILTON.

40, Jewin Street, City,

Oct. 20, 1852.

FRANCE.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

The Transmissibility of Syphilis by Secondary Sores

THE time of the Academy has been almost entirely taken up for the last two months, by the discussion on the transmissibility of syphilis by inoculation with pus obtained from secondary sores. This discussion has been mainly confined to MM. Velpeau and Ricord, the former of whom maintains the transmissibility, whilst the latter, as is well known, denies it *in toto*, and offered to prove the negative before a commission nominated by the Academy. This offer, however, was not accepted by M. Velpeau, but as the discussion was not likely to lead to any decision in the face of the conflicting opinions of such eminent observers as MM. Velpeau and Ricord, it was proposed by M. Bouilland and carried with one dissentient voice, that the commission should be appointed to take into their consideration this question, so important in the treatment of syphilis. The members of the commission have not yet been named, and we are afraid there will be some difficulty in selecting them.

SOCIETE DE CHIRURGIE.

Result of the Ligature of the Large Arteries in 82 cases occurring in the practice of M. Roux.

THE following eighty-two operations comprise the whole number of ligatures of arteries performed by M. Roux, since 1808, and were communicated by him to the Société de Chirurgie. An abstract of the paper has been published in *l'Union Médicale*:—

Arteries.	Operations.
Popliteal artery 1	1 Spontaneous Aneurism (ancient operation).
	3 Recent wounds.
	2 For hæmorrhage after gunshot wounds.
	2 Wounds of artery in operation.
	7 Hæmorrhage after amputation.
Femoral artery 46	1 Femoral aneurism (Hunter's operation).
	2 Femoral aneurism (ancient operation).
	2 Fungous tumour of tibia.
	27 Popliteal aneurism (Hunter's operation).
	10 False aneurism of the bend of the arm.
Brachial artery 20	6 Arterio-venous aneurism.
	2 Hæmorrhage after amputation.
	1 Spontaneous aneurism of the ulnar artery.
	1 Fungous tumour of the radius.
Carotid (common) 6	1 Fungous tumour of the orbit.
	2 Wound of the face.
	3 As a precautionary measure before operations.
Axillary (Immediately below the axilla)	1 Spontaneous aneurism.
4	1 Recent wound, with false aneurism.
	2 Hæmorrhage after amputation at the shoulder joint.
Subclavian ... 3	Secondary hæmorrhage.
External Iliac 2	Secondary hæmorrhage after ligature of the femoral artery.
- Total ... 82	

In these operations the distal mode of Brasdor has not been tried. The old method 16 times; and that of Hunter, with Scarpa's ligature 66 times. The number of cases of true aneurism was 33, of which two only were women. The results were, 10 unsuccessful and 23 cures. The number of false aneurisms was 10, all of which were successfully treated.

Of the six cases of arterio-venous aneurism, for which the humeral artery was tied in each case, four were successful, and in two amputation was necessitated by gangrene or secondary hæmorrhage.

These statistical facts will be read with interest by the English surgeon, by whom the thick ligature used by Scarpa is now carefully eschewed, but the small number of cases (4) in which secondary hæmorrhage occurred, will certainly bear out M. Roux in his attachment to this mode of operation. The difference between the English and French modes of conducting the ligature of arteries is so great, both in the operation itself and in the dressing of the wound, that we rejoice to find that the above facts will form part of a complete work on surgery, which M. Roux is now preparing, and of which the memoir presented to the Société de Chirurgie is only an instalment.

Provincial Medical & Surgical Journal.

WEDNESDAY, OCTOBER 27, 1852.

IN our review of Dr. MURPHY'S "Lectures on Midwifery," published in our last number, we ventured to differ with that gentleman as to his estimate of the value of infant life, when compared with that of the mother. This opinion of ours is protested against by Mr. EDGAR SHEPPARD, whose letter will be found at page 565; but that gentleman, in selecting a particular phrase, has somewhat overstated the assertion which we then made. To prevent further misconception, we reprint the whole passage:—

"Dr. Murphy advocates the employment of turning only when the presentation has been discovered early enough to act before there has been so great a loss of blood as to endanger the mother; indeed, his leaning evidently is to the separation of the placenta in all cases, believing that the life of the child is not to be considered for a moment, when weighed against the mother's. This view is held all through the lectures, to an extent which we think scarcely justifiable. We have no right to hold the scales; but our office is to heal all, whether young or old. It would, we think, be as justifiable to destroy a patient who is attacked with an infectious disease of a dangerous character, in order to prevent his communicating it to a more valuable life, as to destroy an infant (while a chance of its living remains) in order to avoid risk to the mother."

It is true that we say, "that we have no right to hold the scales;" but here, from the context, it is quite clear that we do not mean that the fetal life should never be sacrificed to save the mother's, but that it is not right to destroy the child immediately the mother's life is at all endangered; and that it is not until the case is clearly one of election between the death of the child and that of the mother, or perhaps both, that we are justified in destroying the former. In this case there is, literally, no "holding the scales," but in that propounded by Dr. MURPHY, and supported by Mr. SHEPPARD, we have to weigh the risk which the mother runs, and when that risk weighs sufficient to counterbalance the value of the child's life, then we are to take that life without a moment's hesitation.

Against this law we strongly protest; the laws of God and man alike tells us that we shall not kill, and we object to the breaking of that law without some greater warrant than the mere accidental estimate of the value of the particular

life involved, as proposed by Mr. SHEPPARD. It is, in our opinion, only when Nature says that one must die, that we are justified in selecting the least valuable of the two; and here we agree with Mr. SHEPPARD, that there ought not to be a moment's hesitation, either in selecting the mother's as the more valuable life, or in acting upon this decision as soon as we are satisfied that interference is necessary.

Mr. SHEPPARD asserts, that we "have no business to make the sanctity of infant life an abstract matter, until we are fully assured, as far as our diagnostic powers will permit us, of the safety of that more precious life from which alone the infantine one springs." But this argument will not hold in this particular case, unless it is equally tenable in all, and then we should have to procure abortion or premature labour in all cases in which the pelvis is so small as to cause any danger in the delivery at the full period; as, for instance, where the forceps must be used; in which case the mortality varies from 1 in 15 to 1 in 20. In fact, in all cases where the maternal life is, as far as we can tell, sure to be risked at the full period of gestation, it would be right to prevent that risk by producing delivery at a time when no such risk would be incurred. Now, will Mr. SHEPPARD sanction such a course? We think not. At all events we hope not. But leaving out of the question for the present the discussion of the extreme views held by our correspondent, we will confine ourselves to the consideration of the argument against detaching the placenta in placenta prævia. This question is one of great practical importance, involving not only the expediency, but the abstract question of right, of practising this modern innovation. It is true that Dr. SIMPSON maintained, that nearly one out of three children survived after the detachment of the placenta prior to delivery, and if his facts are to be relied upon as corresponding with the general results of this practice, we should consider the operation, perhaps, justifiable. But we were, and still are, arguing the matter upon Dr. MURPHY's own grounds, viz., "that, although safer to the mother, it is destructive to the child."* And this, we believe, to be now the general opinion. Upon these premises, then, the question resolves itself into this:—Is it justifiable to destroy the child, in order to relieve the mother from a comparative degree of risk,

the extent of which is not even settled by the profession? We know that turning, when practised *early and skilfully*, as shown by the results of the practice of Dr. COLLINS, Dr. CHURCHILL, Mr. NEWNHAM, and many others, is not attended with the danger which Dr. SIMPSON attaches to it. And we also know that it is not fair to compare the mortality from this operation, when performed upon exhausted patients, with that resulting from the detachment of the placenta by the natural powers of the uterus; and we do conscientiously maintain, that until there is a greater preponderance of opinion in favour of the new operation, based upon sound statistical data, and clearly showing that the risk in the one case is extremely great to the mother, and in the other so small as to be put out of our calculation, we should not allow our feelings to get the better of our judgment, as is the case with those who, like Mr. SHEPPARD, maintain that the mother's life is "*infinitely*" more valuable than her unborn child's. We are quite ready to admit, that many maternal lives are sacrificed by delay, but how many infantine lives are destroyed by undue interference with the perforator, or by the detachment of the placenta, it is impossible even to surmise. Of one thing we are quite certain, that it is unnecessary to guard against our feelings, in considering the value of the life of the fœtus, for we are all ready enough, for the sake of the family, and for the sake of our own reputations, to do all in our power to save the mother; but, on the other hand, nothing but an imperative sense of our duty to God and man will ever prevent our carrying out, to the fullest extent, the views propounded by Dr. MURPHY in the following passage:—"If we have any doubt about the mother's safety, not to hesitate one moment because of the child." Against this dictum we must still protest, believing that the mother's life must not only be *endangered*, but that we ought to be satisfied that in our judgment it will be sacrificed, if we do not take the law into our own hands, and sacrifice her child. We would have every obstetric practitioner weigh well the following extract from Dr. CHURCHILL's valuable manual:—

"In fact, it ought to be deeply impressed upon every practitioner that he who destroys the child without due evidence that this is his only resource for saving the mother, is guilty of murder."

WHILE necessarily obliged to give our chief attention to the change in the organization of our journal, we must not lose sight of our higher interests, of those which we hold in common with all our fellow-countrymen—the danger of another cholera epidemic. As it is obvious to all that this terrible scourge looms in the distance, and will assail us again sooner or later, even if the present epidemic current be averted from our shores, it is, worth while to glance at the past, so as to comprehend our present position, and be prepared for the future.

The first visitation of the cholera took us all unawares. Public authority knew not what public measures to adopt. We ourselves were equally taken aback when called upon to buckle to and face the danger at the bedside; that danger passed away, and it was only when the pestilential waves were again seen approaching, and when they menaced again to invade our shores by all else unconquered, that public measures were taken to avert the danger. Between the two epidemics, certain men had foreseen the possibility of turning the public evil to their own good, and some sharp lawyers, briefless barristers, and stray medical men without patients, set going certain sanitary improvements, which the constituted medical corporations of the kingdom should have openly taken up; they should have taught the Legislature what was wanted for the improvement of the public health, and assumed the medical management of the country; for it is plain, that unless the barrister is fit to be consulted in an individual case of cholera, it is absurd to trust to his advice when the general health of the country is menaced by the same epidemic. The profession forsook its duty to the public, and the natural consequence was, that the profession was doomed to be lorded over in medical matters by a set of conceited sanitarians without any knowledge or experience of health or disease. Thus, while in France, MAJENDIE, one of the first physiologists of the age, was at the head of the Board of Health, in England Lord CARLISLE assumed that important position—a man who knows something about POPE's poetry, but who is as ignorant of medical knowledge as a new-born babe. For colleagues, he had the present Lord SHAFTESBURY and Mr. CHADWICK, who were both equally ignorant of medical matters, and their dilemmas would furnish an amusing

history. They began by issuing cholera instructions, which the College of Physicians in London forthwith opposed; they failed in their attempt to close our abominable intramural burial grounds, and to establish a new system of burial; they could not even obtain water for those who live in large towns. Reports have been written, it is true, but the measures inculcated have met with the sterility which will be the lot of every Board of Health of which the medical profession does not constitute the bulk reaping the honours of the business done by them.

Although no credit be due to those connected with the Board of Health, its establishment was a good precedent, and part of its legislation may easily be made applicable to the improvement of the sanitary state of towns. It is well to bear this in mind now that cholera menaces present devastation. When we are called upon to prescribe for a patient afflicted with some complaint which does not yet disclose its nature, what do we do? Are we not guided by general principles?—do we not remove all pernicious influences, have recourse to measures generally found useful to maintain health, and trust to the powers of the living organism to defend it against disease? So it should be with the public health and the health of towns. We should seek to improve the ventilation, the supply of water, the drainage, the system of burying, and, if it be difficult to ventilate many of the rookeries of our large towns, as we have no President to knock down houses by a decree;—if it be difficult to prevent the dead from dangerously affecting the health of the living, because some of our Clergy naturally prefer their own fat incomes to the health of their flocks, we can, it appears, obtain a plentiful supply of water at a trifling expense. This has been done at Nottingham; but it is not generally known how it can be done by smaller communities. We, therefore, draw our readers' attention to the praiseworthy example of the Tottenham sanitarians:—

“Tottenham is not taken under the special protection of the great Sewers' Commission. It is not blessed with the tutelage of the great water companies, nor charmed into inaction by false responsibilities. It enjoys the inestimable advantage of being let alone to take care of itself. The cholera it is true, on its last visitation, found it not only without sanitary precautions, but also without sanitary pretences, and if its inhabitants died under malaria, they were not afflicted with humbug. The calamity was bitter enough for the time, but nothing stood in the way of remedy, and, as there

was no Government Commission appointed to do the work, there was some probability that it might be done. The Whigs had not played fast and loose upon the question, as they did with the general drainage scheme, and the Protectionists had not had the opportunity of trying their hands at sham upon it. Our worthy friends set to the task in the good old Anglo-Saxon, self-helping fashion, and, under the clauses of the General Health Act, tried if they themselves could not provide for the common means of safety.

"The result of their efforts is well worth noting—its comparison with the state of the districts in which no efforts have been made will effectually fix responsibility upon the indifferent and upon the quacks. A cost of £7,500 has been incurred in a district numbering 1,500 houses. The average is just £5 per house. What has been got for the outlay? Eight miles and three-tenths of sewer mains and sub-mains, 10 miles of water-mains and branches, which last are connected with 170 hydrants, that is, self-acting tubes, which, by the mere high pressure of the water, conduct it in any case of fire over the highest houses in the district, so that it is thrown without the need of any usual fire-engine, and may be used to put out a conflagration before such casual assistance could arrive. Two steam-engines and pumps, and an upper and lower reservoir, are included in the cost. Thus the inhabitants, for their £5 per house, have a constant water supply, not kept in cisterns, but, by high pressure, constantly at hand, and perfectly fresh and cool, laid to the very tops of their houses if they choose it, and entailing an expense of about twopence per house each week. They have the readiest and most effectual remedy for accidents by fire, and they have a complete drainage on the most modern system, not indeed so costly as the old brick sewers, but infinitely more effectual, as the 'back drainage' would drive all refuse through the pipes not only before it would have time to taint the air, but before it could putrify. The entire cost, if I understand the report, including the repayment of the original outlay for all these purposes, would not exceed 3d. a week for a £10 house containing a water-closet. Indeed, the report boasts that the expense of the water supply will fall below that of the maintenance and repair of cisterns and their appendages to those who are already possessed of them. It was not to be wondered at that the inhabitants of Tottenham, seeing what has been done for them, are gladly and almost unanimously availing themselves of the advantages so provided. To those communities who may have decision and enlightenment enough to follow this example, it is fit to offer the further encouragement that the cost of putting the Health of Towns Act in operation has been but £66. 14s. 6d.; whereas, as the report too truly observes, a local Act might, at the usual average, have entailed an expense of £2,000."

THE Council of the Bath and Bristol Branch, in accordance with an unanimous resolution, have convened a special general meeting of the Members to be held at the Royal Western Hotel, Bristol, on Tuesday evening, the 26th instant, to consider if any and what steps should

be taken in consequence of the verdict given on the trial—*BOURN v. COX*. And also to consider the propriety of publishing such a letter on medical subjects, in a public newspaper, as was recently done by Mr. JOHN BARRETT, in the case *BOURN v. COX*.

Medical Intelligence.

(From our own Correspondent.)

LONDON, OCT. 25, 1852.

THE medical societies in the metropolis are in the course of resuming their usual avocations. The Harveian is almost in the nature of a private society; but the Medical Society of London, the proceedings of which are generally announced in the medical journals, requires some notice. The first meeting for the present session was held on Saturday, the 9th instant, Dr. Lankester, Vice-President, in the chair, the President, Mr. Bishop, being unable to attend in consequence of an attack of rheumatism, from which, however, he was said to be recovering. The attendance of members was as usual. A goodly number of medical men were present, but the room was not uncomfortably crowded. During the recess some improvements have been effected in the meeting-room; the ventilation is better managed than before; the "draughts from Heaven or blasts from Hell" are now not felt so as to endanger health as was previously the case, and in every respect, indeed, the meeting-room shows that some efficient hand has been at work. Over the seat of the President is a fine bust of Hippocrates. The society, it was stated, was flourishing; indeed, it was never in a better condition: its financial difficulties had passed away, and it was fully anticipated that the amalgamation with the Westminster Medical would prove in every way an excellent measure for its ultimate benefit. Many papers from authors of repute belonging to the society had been promised for the commencing session, and the shelves in the library, which, although filled with an ample supply of ancient medical works, had yet room for more, especially if recent ones, had had numerous additions made to their contents during the recess.

The first communication made was by Dr. Hawkesley, and had reference to an improvement in the air-mattress, or bed, for invalids suffering from diseases of the urinary organs which prevented their retaining the usual excretion. It consisted simply in the perforation of the mattress by a tube made of vulcanised India-rubber, which on its upper surface presented an infundibuliform, or funnel-shaped cavity, into which the fluid ran as it passed away, and thus tended to prevent irritation of the skin, and the subsequent bed-sores. The patient, it was said, might be moved once or twice a day, and the surface of the mattress sponged and dried. *Par parenthèse*, Dr. Hawkesley remarked that he had found oxide of zinc and water the best application when the skin is irritated by the urinary discharges. Mr. Box showed the improved air-mattress duly inflated.

Dr. Lankester next exhibited a small box or case,

containing several acupuncture needles, ranged in a circle, which on being applied to the skin and pressure exerted on the other end of it, caused the needles to penetrate to a greater or less depth, as might be desired. In this respect it might be compared to the scarificator in cupping, except that it was worked by pressure and not by a spring. Dr. Lankester said it was used on the Continent in cases of rheumatism, &c., croton-oil being afterwards rubbed in on the wounded parts as a rubefacient, but in that respect he could not say it was better than the ordinary croton-oil ointment, or liniment. He had met with it in France, and finding that those medical men in this country to whom he had shown it had not seen or heard of it before, he had thought it might be useful to exhibit it to the society.

Mr. Richardson, of Putney, next brought forward a specimen of enlarged spleen, taken from a patient of Dr. Smith's, at Richmond. The deceased had been ill several weeks, and a tumour in the abdomen had been discovered, but its nature not recognised. The spleen weighed 3½ lbs. The left kidney, on which that organ rested, was partly atrophied, the right being of the natural size, which he (Mr. Richardson) accounted for by saying that the compensating increase in size, &c., of one organ, when its fellow is atrophied, rarely if ever occurs after the 30th year. The heart was also very much atrophied, the left cavity of the pleura full of fluid, and the lung much compressed. Death occurred by asthenia.

Dr. Rogers showed a specimen of calcareous deposit in the aorta, and on its semilunar valves, with extensive enlargement and softening of the heart, and commencing fatty degeneration of its walls. As he was only called to see the deceased, aged 37, when *in articulo mortis*, he could not institute a careful stethoscopic examination, but there were great regurgitation and obstruction at the site of the semilunar valves.

This was followed by a short but interesting paper by Dr. Cogswell, who detailed sundry experiments made by himself and others, on frogs, rabbits, &c., with hydrocyanic acid, the result leading him to conclude that that powerful agent exercised a great influence on the larynx and trachea.

The evening concluded by reading a highly interesting and philosophical paper written by the president, Mr. Bishop, "On some of the principal attempts to reduce the Functions of the Human Body to an exact Science," in the course of which the author sought to bring the physiological and some of the pathological phenomena of the human apparatus to the certainty of mathematical formulæ. It elicited some discussion, to which the absence of the writer was a great drawback.

The Pathological Society, one of the most recent, and at the same time one of the most valuable medical societies in the metropolis, commences its session on the 19th instant. Meanwhile the council have published their sixth annual report, a volume replete with most important information on every subdivision of pathology, illustrated by some excellent reports on sundry of the cases, and by useful and careful engravings. This Society, beyond a doubt, is destined to take a high place among the scientific bodies of the United Kingdom.

The Royal Medical and Chirurgical Society, though last, certainly not the least of our medical institutes, delays its commencement until the second Tuesday in next month, when we may expect to be able to enrich our reports with notices of the valuable papers to be brought forward for discussion at its meetings.

At the succeeding meeting of the Medical Society of London, Mr. Bishop, the President, was still unable to take the chair. Although recovering from the attack of acute rheumatism under which he has now been suffering for some time, he has not yet convalesced sufficiently to encounter the risk of exposure to the influences of night air at this season of the year. His place was worthily filled by Dr. Edwin Lankester, one of the Vice-Presidents of the Society.

A singular and interesting case of emphysema was described by Dr. Burke Ryan. His patient was an infant, suffering from scarlet fever; from the commencement of the attack it had suffered from great depression and dyspnoea, and the occurrence of the eruption was simultaneous with an emphysematous appearance, which commenced about the jaws, and extended over the whole of the upper part of the back, and thence to the integument covering the chest. The case soon ended fatally. Although Dr. Ryan was not allowed to institute a *post-mortem* examination of the body, he felt satisfied that the emphysema did not originate in the lungs, but was caused by the spontaneous decomposition of the tissues, induced by the poison of scarlatina. As an illustration of this opinion he quoted several similar cases connected with zymotic disease, but acknowledged that he did not know of any in which the scarlatina poison had previously produced such a result. He purposes publishing the details of the case in full in one of the medical journals, and the profession will be enabled to see his reasons for that opinion given at greater length, and will be enabled to ascertain their value.

A singular exhibition was made subsequently, by Mr. Weeden Cooke, one of the surgeons connected with that newly-started aspirant for public and professional favour—the Cancer Hospital. He showed under the microscope sundry insects, of the shape of bugs, but rather more ovoid, and others eel-like in figure, which he had found in the matter secreted by a cancerous ulcer on the tongue. He said that he had examined many such sores in various parts, but had not, as yet, found these insects anywhere else, but always on the ulcers of the tongue.

The parts concerned in the operation for excision of the elbow-joint, some time subsequent to the operation, were next exhibited by Mr. Henry Smith. The most interesting feature of the case consisted in the very rapid occurrence of necrosis of the humerus, caused by a fall, fracturing that bone, when the patient, a very strumous boy, was very nearly convalescent after the operation. The shaft of the bone, from the fracture downwards, was necrosed; in the course of a week Mr. Smith felt himself called upon, consequently, to amputate at the shoulder-joint. So rapidly did the death of the bone occur, that Dr. Camps could not credit its dependence on the accident, but was inclined to refer it to pre-existing disease of the bone, connected with the state of

the elbow-joint, for which excision had been practised. This opinion was controverted by Messrs. Gay, E. Canton, and H. Smith, all of whom held the opposite view. The two former detailed cases in which the progress of necrosis was equally rapid; and Mr. Gay stated, that within the last twelve months he had seen more cases of necrosis than he had done during his previous professional career. So prone indeed was the osseous structure to take on that form of diseased action, that the slightest injury would induce it. A blow, by no means severe, on the tibia, had induced necrosis of that bone, extending to the knee-joint, and necessitating amputation in the lower-third of the thigh, and singularly enough the shaft of the femur subsequently became necrosed. This, Mr. Gay stated, had occurred in two instances in his practice during the last twelvemonths, so that he was now led to regard every injury to the bone, however slight it might appear to be at first, as likely to involve most serious consequences. Mr. Weeden Cooke regarded this tendency to necrosis as in some way connected with the tendency to asthenic disease, which has now been noticed for some years, and added, that he had seen it ensue in several cases of the furuncular and carbuncular endemic now prevailing.

An excellent and most valuable paper by Dr. Risdon Bennett, "On Cases of Empyema, discharged through the Bronchi, and on the Character of the Purulent Pleuro-Pneumonia," closed the *sedesunt*. After detailing at some length several interesting cases of empyema, caused by the pleuro-pneumonia, in two of which the matter was discharged through the bronchi, and the patients recovered, Dr. Bennett proceeded to show the difference between the epidemic pleuro-pneumonia and the ordinary sthenic form of that disease. It usually commences either by pleurisy or catarrh. The pain is very severe, and effusion occurs rapidly, and to a considerable extent, soon becoming purulent: cough not troublesome; the sputa copious, and more or less tenacious and glairy, sometimes streaked with blood, at others resembling prune juice, or of a dirty-green yellow colour; dyspnoea not urgent, nor the respirations much increased in frequency; skin moist and clammy; tongue covered with a creamy fur; pulse rapid, soft and feeble. The physical signs indicate the rapid spread of inflammation over a great extent of surface, but usually confined to one side; although many cases of double pleuro-pneumonia fell under Dr. Bennett's notice. The principal character of the inflammation, besides its asthenic signs, was the tendency, not to solidification or hepatization of the lung, which rarely occurred, and never to any extent, but its rapidly assuming the suppurative form, and its liability to run into gangrene. Dr. Bennett regarded it as a variety of erysipelatous inflammation; and the treatment consequently was stimulant, and not antiphlogistic. Local bleeding was serviceable at the very commencement of the attack; but was practised only to a limited extent. Five-grain doses of compound pulverised ipecacuhana, with a grain of calomel or grey powder, given every six hours, were found of use; but counteraction by means of blisters, with ammonia, combined with its acetate, and serpentaria or senega, constituted, in his opinion, the best plan to be adopted. Beef-tea and wine were also necessary. The disease

was found to be very fatal, and with great rapidity. In some cases, so rapid and great was the prostration, that stimulants were requisite *ab initio*. Dr. Bennett's views were generally supported by those who followed him, except that Dr. Theophilus Thompson considered it injudicious to give opium, as it lessened the expectoration and increased the dyspnoea, tightening also the cough. Both Dr. Thompson and Dr. R. Bennett alluded to the operation for paracentesis thoracis, which they considered was indicated, not by the increasing dyspnoea, but by the inability of nature to force a passage for the secreted pus, either by bronchi or externally. If there be evidence to show that by either way the matter is likely to be discharged, then the operation is not to be practised.

The first meeting of the Pathological Society of London was held on the 19th instant, Mr. Caesar Hawkins presiding. The attendance was exceedingly good; in fact the rooms were crowded. There can be no doubt but that this Society will, ere long, embody all the talent in the metropolitan sections of the profession. After a short congratulatory address, delivered by the President, some interesting specimens of morbid anatomy were exhibited, and commented on by the members. Dr. Peacock commenced by an attempt to demonstrate the muscular character of the valve which closes the foramen ovale. He said that as he had entertained doubts as to the accuracy of the explanation generally given of the closure of the foramen, he had made a series of dissections, and had distinctly ascertained the muscular character of the parts. This, however, was not a discovery, nor did he claim it as such, as Senac had also distinctly demonstrated the fact. The muscular fibres could be seen on examination, he added, passing down from the coruna, and their action was to draw up the valve. These fibres are almost, if not entirely, derived from the left auricle, not from the right. This muscular character of the valve may be seen very clearly in the hearts of some fishes, more especially in that of the young turtle. Dr. Peacock concluded by showing in what way this condition of the valve may be applied, to explain certain malformations and changes in the pathology of the heart. Haller denied the existence of these muscular fibres: he admitted having seen them, but asserted they were not constant in their presence.

An interesting case of hernia of the bladder into the right scrotum was next exhibited by Mr. Pilcher for Mr. Lane. There was also a large intestinal rupture on the left side. The prostate was very large, and the bladder much congested and diseased, the hernia having existed on the right side for ten years, and yet no difficulty had been experienced in evacuating its contents until about a fortnight previously, when the use of a catheter was required. The man died in a few days afterwards. Mr. Baker, who attended the poor fellow in the first instance, mentioned, as singular facts, that he had been able to retain the urine for four or five days on one occasion, and that when it was drawn off it filled a large washhand basin. On a subsequent occasion a still larger quantity was drawn off by means of the catheter.

In the volume of "Transactions" recently published

by the Society, is contained the records of a case of fatty degeneration of the uterus subsequent to parturition, by Mr. Rainey, of St. Thomas's Hospital. The case was brought before the profession to show the manner in which absorption of the uterus, enlarged during pregnancy, takes place, an opinion being now afloat that the tissues of the womb undergo fatty degeneration, and are subsequently entirely absorbed; or that, in fact, there is a new uterus in every pregnancy. Although this view certainly appears to be a most singular and strange one, it is not unsupported by facts. In addition to the case above alluded to, another was brought forward on the 19th instant, by Dr. Bristowe and Mr. Rainey, more strongly illustrative of the theory, inasmuch as the woman having died a week later, as regards parturition, than the other, the fatty degeneration was much further advanced. Mr. Rainey's object in showing the specimen was stated to be to prove that this peculiar degeneration was not owing to inflammatory action, but was a natural process occurring after parturition. The patient died from metrorrhæmia, with secondary abscesses in the pericardium, heart, lungs, &c. These views, respecting the changes in the uterine structures after delivery, were first promulgated by Dr. Kilian, and have since been strongly advocated by Mr. Rainey and others.

Dr. Bristowe subsequently showed a specimen of cancer of the liver and right lung, with, as he fancied, tubercle freely deposited in the left lung. As, however, there was considerable doubt whether the matter in that organ was really tubercle, and as Mr. Rainey, after examining it under the microscope, had given a decided opinion against its tuberculous character, it was referred to Dr. Jenner and Dr. Brinton, to examine and report upon it at the next meeting. The coexistence of cancer and tubercle in the same person has hitherto been considered as almost fabulous.

A case of extensive fatty degeneration of the heart, occurring in a female about 30 years of age, was brought forward by Dr. Sibson, under whose care she was admitted, in a dying state, into St. Mary's Hospital. No history of the case could be obtained from her, and as the case was quite recent, Dr. Sibson had not had time to collect any particulars from her friends. The mitral and aortic valves were almost completely converted into fat; but the walls of the ventricles, although they had undergone some change, were not destroyed by degeneration. The heart weighed fifteen ounces. The tubules of the kidneys were partly loaded with fat, and some of the malpighian tubes were congested.

Dr. Handfield Jones exhibited a diseased and degenerated placenta, the fœtus being born dead, the evidences of its vitality in the womb having ceased about the fifth month. The foetal surface of the placenta was normal, but the maternal appeared as if it were atrophied; it seemed to be a thin layer spread over the foetal portion, with trabicular lumps, as it were, in different parts. In the maternal fibrous homogeneous membrane, there were traces of fibres, of cell-growths, and nuclei; none of blood-vessels, except, indeed, a series of outlines indicative of the course of the veins, all of which were obliterated. The cell-growth described by Goodsir was completely atrophied, many of the villi were opaque, from the presence of calcareous and oily

substances; some, however, were simply atrophied. What was the nature of this change? Rokitsanski referred it to inflammation, but he (Dr. H. Jones) held a different opinion, for there was nothing to show the presence of inflammation. He regarded it as owing to an unhealthy condition of the blood, and as allied to cirrhosis of the liver, and such like diseases.

ON

THE OCCURRENCE OF BERBERINE IN THE COLUMBA WOOD OF CEYLON, THE MENISPERMUM [COSCINIUM] FENESTRATUM OF BOTANISTS.

BY JAMES D. PERRINS, ESQ.

THE following investigation was made in the chemical laboratory of St. Bartholomew's Hospital, under the immediate supervision of Dr. John Stenhouse. Dr. Stenhouse having had for some time past a quantity of wood of the *Menispermum fenestratum* in his possession, suggested to me this investigation. I am anxious, therefore, to acknowledge my obligation to him, not only for the material, but also for several valuable suggestions in the course of the inquiry.

Hitherto the chief source of the alkaloid berberine has been the root of the barberry, *Berberis vulgaris*. Bödeker, however, about four years ago, ascertained its existence in the columba root of pharmacy, the *Cocculus palmatus*, where it occurs in small quantity associated with columbine. The following remark is made in the *Chemical Gazette* for 1849, vol. vii., p. 150:—"The occurrence of berberine in *Berberis* and *Cocculus* is remarkable in a physiological point of view. Bartling places both of these families, the Menispermæ and Berberidæ, in the class of the Cocculinæ, which is in accordance with the fact of both containing the same principle." As berberine has now also been found in another of the Menispermæ, the accuracy of Bartling's view seems to be greatly confirmed.

The following was the process adopted for the extraction of berberine from the *Menispermum fenestratum*. A quantity of the wood, which had a bright yellow colour, resembling that of quercitron, was rasped, and then treated with successive portions of boiling water till it had become nearly tasteless. The aqueous decoction acquired a deep yellow colour and an intensely bitter taste. It was next evaporated carefully to the consistence of an extract, then introduced into a flask and boiled with ten or twelve times its bulk of rectified spirit of wine, filtered while hot, and the residue boiled with a further quantity of spirits, which dissolved the berberine, and also a quantity of resinous matter by which it was accompanied. The alcoholic solution was then introduced into a retort, and the spirit carefully distilled off, until the residue on agitation appeared to have nearly the consistence of oil of vitriol. It was then set aside in an open vessel, and in the course of

twenty-four hours the liquid became filled with a mass of impure crystals.

After draining off the mother liquor, these crystals were washed with a small quantity of cold spirit, redissolved in boiling alcohol, and set aside to crystallize. Their complete purification was attempted by repeated crystallizations. It was found, however, that a small quantity of resinous matter adhered obstinately to the crystals, causing them to remain of a brownish-yellow colour. This brownish tint was ultimately entirely removed by solution in spirit of wine and digestion with a little purified animal charcoal, the pure berberine crystallizing from the solution in beautiful bright yellow needles. The crystals were found to contain nitrogen, and their behaviour with various reagents corresponded exactly with those of berberine.

As these crystals were very soluble in boiling water, a quantity of them was dissolved in that menstruum; and on the addition of the requisite amount of hydrochloric acid, a crystalline precipitate was immediately obtained in the form of long, slender, golden-coloured needles, of a fine silky lustre.

This salt was dried in a water-bath at 212° Fah., and subjected to analysis with the following results:—

6·25 grs., ignited with chromate of lead, gave 14·398 grs. of carbonic acid and 3·2 grs. of water.

The nitrogen was determined by Willis's method. 8·18 grs. of salt gave 4·94 grs. of the double chloride of platinum and ammonium.

The chlorine was determined as chloride of silver. 3·59 grs. gave 13·5 grs. of chloride of silver.

The *Menispermum fenestratum* is, according to Ainslie, a large tree, which is very common in Ceylon, and an infusion of which has long been employed by the Cinghalese as a valuable tonic bitter.

Gray, in his *Supplement* to the Pharmacopœia, informs us that this tree is known to the Cinghalese by the names of Woniwol and Bangwellzetta.

Berberine may easily be obtained in very considerable quantity from columba-wood, the whole of which it pervades, and of which it is the colouring principle; and if, as I suspect, the resinous matter accompanying it consists chiefly of altered berberine, improved methods of extraction, such for instance as the employment of a vacuum pan apparatus, would in all probability still further augment the amount of product.

I am informed that berberine is employed as a remedial agent on the Continent, but its scarcity seems hitherto to have prevented its introduction into the medical practice of this country. As a good source for it has now been pointed out, it may be expected that berberine will take its place with the other alkaloids in our materia medica. To prevent misconception from the similarity of names, it may perhaps be well to remark, that berberine and bebeerine are very different substances,—the latter being the active principle of the bark of the bebeer tree of Guaiana, and as yet has not been obtained in a crystalline form.—*Philosophical Magazine*, August.

St. Bartholomew's Hospital, July 20, 1852.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 15th instant:—Robert Austen Allen, Stewarts Town, Tyrone; Carl August Ludwig Bauer, London; Thomas Henry Cheate, Burford, Oxon; Robert William Cockerill, Greenwich; Charles Davenport, Welford, Gloucestershire; Stephen Donegan, Cork; James Crowder Eastcott, St. Pancras; Amos Ingham, Hebdenbridge, Yorkshire; Edward A. Middleship, Hon. East India Company's Service, Bengal; Matthew Morris, Haverfordwest, Pembrokeshire; James Nicholls, Trekenning, Cornwall; James Winter, Dublin.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, the 7th instant:—Henry Vandyke Carter, Scarborough, Yorkshire; Robert Newcombe Day, Harlow, Essex; Thos. Peete, London; Robert Whitby, Maunham St. Peter, Norfolk.

Gentlemen admitted members on Thursday, the 14th instant:—Charles Blatherwick, Titchfield, Hants; Angus Macmillan, Hull; Albert Massey, Camberwell; James Nicholls Trekenning, Cornwall.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

The Central Council of the Association beg to call the attention of those members whose subscriptions are in arrear to the following resolutions passed at the Anniversary Meeting, held at HULL, on the 7th and 8th of August, 1850:—

“But if any Member's subscription remain unpaid twelve months after it shall become due, the *Medical and Surgical Journal*, and other publications of the Society, shall be withheld from such Member till his arrears be paid; and when any Member has been in arrears of subscription for the space of *three years*, application shall be made for the same by the General Secretary, and if the arrears be not paid in *three months*, the name of that Member shall be omitted from the list of Subscribers; but this omission shall not be deemed, either in honour or equity, as releasing any Gentleman from the subscriptions owing during his Membership.”

Those gentlemen who have not yet paid their subscriptions for the CURRENT YEAR, or who are in ARREARS, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association at Worcester.

All post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

J. P. SHEPPARD.

Worcester, October 23, 1852.

Secretary.

TO CORRESPONDENTS.

Communications have been received from Dr. Black, Mr. Higginbottom, Dr. Merel, Mr. Colthurst, Dr. Turnbull, Mr. Norris, Dr. Duncan.

LECTURES
ON THE
DISEASES OF CHILDREN,

DELIVERED IN THE

Chatham Street School of Medicine, Manchester.

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Vienna, etc.

LECTURE XV.

Rheumatic fever and local affections continued. Course of the different forms—the acutest rare in children; disposition to affections of the heart, which in children attack generally the pericardium; the mildest is the most frequent in childhood and infants; the rheumatic cough; many differences of rheumatic fever in form and course; transitions and issues of rheumatic fever, and of the local affections; pathology—the chemical as well as the anatomical—as yet very imperfect; diagnostical characters of the fever and local affections, objective and attainable in the speechless age; resemblance to some form of tuberculous disease; disposition of children in general, and of the different ages to different forms. Cause: electric influence. Complications.

GENTLEMEN,—I will proceed now to consider the course of different forms of rheumatic fever, in connection with different local affections. The course of the acutest form, in which almost all the principal joints are affected, which I said is exceedingly rare under the third year, is the same as in adults, only the exhaustion by both fever and pain, appears sooner and is severer in the child. It is a sad impression to look at the young patient, even six or eight years old, with his greater sensibility of nerves and less moral power, when under so severe a suffering. This form, if once established, as far as I remember, takes in favourable cases between six and eight weeks or more, before the child can be said to be recovered.

The less severe degree of the same form—viz., where only one or two joints are affected, though the fever commences and runs very high, is more frequent in young children, but less dangerous and shorter in duration. In favourable cases about three or four weeks are enough to perfect the recovery.

In the articular form there is more disposition than in others to rheumatism of the heart, but certainly less than in grown-up people. I may be allowed to state, the acuter the rheumatic fever, and the acuter the swelling of the joints along with it, the more there is disposition to affections of the heart. According to my experience, the difference between grown-up people and children respecting the kind of heart affections of the rheumatic source, is this: in the man it is not rare, that after only three, four, or more days, of an acute attack of rheumatic fever, the heart becomes affected, and slow valvular alterations may take place. In young

children, if during fever inflammation has to come, that of the heart or pericardium, as well as pleurisy or meningitis will, as a general rule, appear the first day or two; as to that of the heart, I always, and only observed pericarditis, with or without pleurisy. On the whole, I have very seldom met with inflammations of the heart in infants; more often with rheumatism of it.

Finally, there is the mild form of rheumatic fever, connected with only a slight degree of swelling, or merely with rheumatism, in most of the cases either of one of the knees, or of the costal pleura, the mediastinum, or fibrous and nervous textures of the trachea, all without inflammatory action, with little or no danger, but not seldom a good deal of annoyance to us.

The mildest form being the most frequent in young children, and almost the only one to which I have seen even nurslings to be subject, I will therefore just give you a few outlines of it. Under a sudden change of temperature, even without having been directly exposed to cold, the infant shows, in most cases in the afternoon or evening, the already described precursory and following symptoms of a primary paroxysm in more or less moderate or vehement degree. Vomiting is not unfrequent. Soon after the onset of fever, seldom later than ten or twelve hours, the child moans interruptedly at first, and by-and-by continuously; it has a restless sleep; when taken up in the arms, his breathing appears to be shorter than usual, or even cut short by pain. The child is irritable and holds languidly his head; it bursts easily into crying, which in some instances of the kind is prevented by pain, when on close examination, we find the presence of pleurodynia; but sometimes we cannot verify it. Either with or without this, now and then the infant coughs—a short, superficial, dry, and evidently painful cough. By-and-by, perhaps, there may appear the signs of pain with little or no swelling of one of the knees, or nothing of the kind. Now, as to the first night, that pleurodynia, if present, may pass into pleurisy, or that dry and painful cough, at first without other physical sign, may be the forerunner of bronchitis. But frequently you will find that the next twelve, or twenty-four hours, will bring on a critical and beneficial perspiration, and ere twenty-four hours are past the child will be restored to health. This comes very near ephemera in every appearance. If this be not the immediate issue, at least the character of remission and exacerbation will throw some light upon the disease,—the signs of pleurodynia will persist, and that dry and painful cough will continue so, without any material indications on auscultation or percussion. Perhaps some slight swelling of one of the joints, or pain under pressure and bending, will likewise persist, with peevishness or disposition to crying. The dry and painful cough, sometimes remarkably intermittent, may return, and persist for a few days or weeks, with slight febrile alterations, partly with dry and hot, and partly with moist skin.

This cough, with little or no bronchial râles, but more pain on coughing, (*i. e.* under the concussion of

the chest) than in bronchitis, I may be allowed to call "rheumatic cough." It is not bronchitis, or bronchial catarrh. I cannot exactly point out its seat, whether it be in the muscular and fibrous tissue, or the nerves of the windpipe. You will easily find out what I mean, and form for yourself a clearer idea of the whole form of fever in question, if you bring before your mind the same as it occurs in grown-up patients.

It is not said that the whole group must occur just as I have described it. The same mild form may bring on a more or less acute headache or other pain, fixed or erratic, of the different parts of which I have spoken in my last lecture. In general, rheumatic fever presents in the child as well as in adults, infinite varieties of form, course, and issue. I have seen cases, where rheumatic fever had set in with so much vehemence, that already the second day the child presented that alarming aspect, to which I gave the name of "hypersthenic stage," with 180 and more pulsations, twitching, tremor, and the like. Only the third day the nature of the fever and the seat of pain became clear. In other rare instances the fever continued moderate two days or more, the pulse not above 130—140, and with a remittent type, with simultaneous signs of some pain, of which I could not make out the seat, and only on the third or fourth day one of the knees commenced to swell, and in proportion as the swelling increased the fever abated and ceased. Others again, I remember, in which an alternating relation existed between some local pain, and the paroxysms, or the latter and a serous diarrhoea, each discharge from the bowels being preceded by pain.

Profuse sweat, without alleviation, with a low temperature or even coldness of the skin, is always a bad symptom, but rare in young children. I have seen, however, a few instances of a striking appearance. Spasms of the bladder and dysuria belong also to the occasional phenomena; the child cries vehemently, and then the careful mother notices the urine coming for some time drop by drop, and at last freely, when the child at once will cease to cry. This happens when the urine is exceedingly overcharged with lithate of ammonia, and the case is by far more obvious with children than with adults. This seldom happens before the third or fourth day, and frequently later.

In almost all forms of rheumatic fever of children, you will observe from the second day onwards, remissions once or twice every day. The transition from local rheumatism (acute and febrile) to inflammation, if it has to come, in my experience, happens generally sooner than in adults, and in children under two or three years, the first or second day. Suppurative inflammation of a joint is a rare issue of rheumatism. I remember a few cases only where the disease occurred always in one of the knees. The pulse is in proportion to the languor more frequent than in other fevers. Sometimes you will count 160, 180, and more, where the whole aspect of the little patient would not have led you to suspect it. When it protracts its course longer than a week, with a low remittent type, there is commonly a high degree of nervousness perceptible in children. Intoler-

ance of medicine is also more frequent here than in other kinds of fever. The recovery will almost constantly be announced or connected with equable gentle perspiration (instead of profuse) with an adequate general temperature of the skin. Sometimes, however, particularly within the first three days, also profuse sweat proves critical and beneficial, provided it be equable, and connected with an adequate temperature of the skin. If in ratio to the cessation of the fever follows swelling of a joint, which is neither very hot nor painful, this I found to consist merely of thin serosity, and it vanishes easily by absorption.

Transitions or issues, in less favourable cases, which of course are very variable in themselves, are much dependent upon the constitution of the child. The worst transitions happen in the scrofulous. Rheumatic fever, however high, seldom exhausts the vital powers so far as to cause death, merely by the febrile action. I have seen only a few cases, in which the little patient died apparently by collapse, without equivalent anatomical changes, though, as far as I can recollect, in most of these cases, sudden and profuse serous diarrhoea had occurred, or the child was extremely tender and weak.

Rheumatic fever passes occasionally into tuberculous phthisis, or better to say, contributes to the development of scrofula or tuberculosis, by those profuse unwholesome sweats.

I have seen typhus complicated with local rheumatism at the beginning of the fever, but do not remember instances of transition from rheumatic fever into typhus. But I have noticed in some cases the transition into remittent gastric fever, or what you may call the *infantile remittent*. These transitions took place when the rheumatic fever was connected with abdominal rheumatism; a bad kind of diarrhoea rendered the consecutive remittent form dangerous, and sometimes fatal to the child. This happened in such children as were under the third year of age. A similar transition I have seen also from the articular form but rarely. I remember an instance of this kind, in which the swelling of the joints disappeared in proportion as the low remittent form developed. This case ended in death.

Inquiring into the transitions and issues caused more directly by the rheumatic local affections connected with the fever, nothing is more dangerous, and more frequently the cause of death amongst all kinds of local rheumatism in infancy, than profuse serous diarrhoea; and this is not always in proportion with anatomical signs of congestion or inflammation in the intestines. I am sure it can merely be muscular or nervous rheumatism, and the discharge effected by sympathetic action. Dangerous, and eventually even fatal, I saw to be also the rheumatism of the substance of the heart at its very onset. I have seen cases of the kind in young children, (I believe three or four,) and although it was, and it will be, impossible to demonstrate in these cases the cause of death anatomically, I have the fullest conviction it was rheumatism of the muscular tissue of the heart. One case may serve you as example. I could describe it with minuteness, but will only in a

few words mention that it was the child of a friend of mine, twenty months old. After visible rigor, considerable dry heat, with an extremely frequent pulse. Soon after the beginning of the fever, (perhaps five or six hours,) the moaning got a very painful expression, then the respiration from hour to hour heavier, sometimes a short dry cough, increasing palpitation, when at the same time the pulse became intermittent and irregular, from time to time fainting, lips livid, extreme expression of anxiety and pain in the countenance. On auscultation and percussion over the heart, no endocardial murmurs, no frottement. Palpitation and some irregularity in the pulsations. I could ascertain, by careful exploration, the total absence of pleurodynia. After prescribing I went away; next morning I heard of the fatal issue. The parents told me that the little girl, from pain, became blue in the face, respiration at once stopped, and death followed in a slight convulsive movement, about fourteen hours after the beginning. In the night, though the results of auscultation were negative, I thought it might become pleurisy or pneumonia, and therefore ordered leeches; but they were too late, and insufficiently applied. On *post-mortem* inspection I could detect nothing, except a great coagulum in the left ventricle, proving that the heart must have, for some time before death, imperfectly expelled the blood, and the other secondary changes—congestion of venous blood in the lungs and brain.

Now, I think, it would be erroneous, to regard this as commencing endo- or peri-carditis, because in this case fifteen hours would be sufficient to produce changes in the envelopes, visible and unequivocal enough; but I think I am right in supposing rheumatism of the heart as the cause of death. And when I say, acute rheumatism—although inflammation frequently at once joins it—still I do not identify it with inflammation. Rheumatism of any muscular texture may persist very long as pure pain, without causing visible changes; that of the heart, as I know from adults, causes fits of atrocious pain, with occasional contractions. Of other cases I have only retained a superficial recollection. That young children may die under an attack of the kind, whilst adults resist it, is, I believe, not to be wondered at.

The transition of local rheumatism into inflammation, which in the joints so frequently causes more or less irreparable damages, causes great danger to life, in young children almost certain death, if this happens in the pericardium.

Dangerous, and sometimes fatal, is also the transition of rheumatism into meningitis, and I really believe that many a simple *peripheric* meningitis may be traced to rheumatic origin. I can state, however, that acute meningitis in my practice always developed itself within the first two days of an acute fever; nor can I remember one single case connected with acute articular rheumatism, in fact I am so satisfied about that, that frequently I did my best to evade leeching, when in the course of acute articular rheumatism symptoms of the head caused alarm. I considered, and do consider, these cases as rheumatism of the scalp, or the meninges.

Hydrocephalus I have seen in the course of a long remittent rheumatic fever, but not real meningitis.

That rheumatism of the pleura frequently passes into pleurisy, is a well known fact. All transitions and issues mentioned till now, are, however, more or less rare in comparison with that into chronic rheumatism in its different forms. These are more or less troublesome, or dangerous to the integrity of the joint or joints, or to life itself, in a long and indirect way. Here again I must point out a difference between childhood and mature age. In the latter, chronic rheumatism, when fixed in the heart, frequently causes exudations of lymph within the cavities, or more specially structural changes in the valve apparatus. This, whatever some respected authors may state, must be extremely rare in young children, nay, rare even in those of four or five years, because I could never verify it amongst so great a number of children in my practice. And I beg to remark, that I have had to attend many cases of chronic recurrent rheumatism of the heart. I have already had to attend here (in Manchester) a case, 4 years of age. But the affection persisted in these cases as mere rheumatism. I think that in adults there is a degree of gouty dyscrasy just as frequent as the scrofulous is in children; and this I believe accounts for the predominant frequency of endocardial deposits in mature patients, just as well as for the predominant frequency of destructive swellings from articular rheumatism in children. In conclusion, chronic endocardial rheumatism, fixed and inflammatory, I regard as rare in the early period of life.

The *pathology* of the disease in question is as yet very obscure. The theory of the lactic acid is exploded. The brick-coloured deposit has been noticed since the remote antiquity as characteristic, and really it is more striking in quantity and aspect than the same kind when it happens under abdominal disorder; but, at the same time, lithates are present (in less quantity) in the healthy urine, and the respective elements always in the blood: so the sediment of lithate of ammonia, in itself, gives no sufficient foundation for the pathology of rheumatism. We know not the rheumatic change in the blood, and I may be allowed even not to look at the dyscrasy of the blood as the pathological source of rheumatism, but probably as secondary to a trouble of innervation by thermo-electric, or electric influence upon the spinal system. Every local rheumatism commences with pain, and frequently persists as severe pain for years. This, it would appear, points at least to an essentially nervous element or source of it. Nor has anatomical pathology of rheumatism attained to a more satisfactory, still less to a specific character. We know of no essentially rheumatic products. In the exudations and swellings all is referred to acute or chronic inflammation in its different degrees, productive of serosity, lymph, pus, and the like, and to complication with scrofula, just as in adults to that with gout. The white swelling of the knee has frequently a rheumatic origin, but, I think, always a scrofulous ground. Those authors who consider rheumatism and gout as identical, ought to study it in children. How is it that

some forms never occur in infancy and early childhood? How is it that the lithate of soda concretions are not formed in the joints of children? And finally, after all that I have seen, I believe it will by and by become established, that the endocarditis of children—in those rare cases in which it happens—is scarcely ever of a chronic nature, and its effects, which are so frequent in adults, and of a particular character on the valves, are scarcely met with in children.

The diagnostic character of rheumatic fever in children, considered in its general febrile symptoms, consists, as in adults, in a *remittent type with profuse perspiration*. The local affections connected with it vary much in their form, intensity, and relation to the fever; their seat is the fibrous, serous, and muscular tissues and nerves; and their commencement is generally pain in these parts.

As in little children local rheumatism is not always at once discoverable, we must consider the whole of the disease together. It happens that sometimes, in the beginning, the fever, with its alarming influence upon the child, is the predominant or absorbing subject of our observation; and it will appear for some time just like any primary fever; but the careful observer will generally find out, within the first twenty-four hours, the presence of some salient local pain. Be it, then, that we cannot discover at once the seat of it; still, as soon as we see that it presents salient remission, with perspiration or profuse sweat, followed again by dry hot skin, with renewed signs of pain,—be it, I say, that we are at that time unable to find out its seat, we may conclude, by the mentioned appearances, upon the rheumatic nature of the fever. If the sweat is profuse without alleviating, then we are certain about it.

The brick-coloured sediment is also of some diagnostic value; but generally this appears only in the further course, when already other enlightening signs have been disposed of; and with little children there is a great difficulty of collecting the urine. We can in this case only look at it on the clothes, both immediately when emitted, and some hours afterwards, by the stain. Thus it may happen that we find at the second inspection the colour of the stain, which was at first reddish, changed into brick-colour, and the cloth thickly scattered with similar-looking little bodies. On the whole, I find the urine is less distinctive of rheumatism in children than in adults.

No doubt pain and irritation in joints or muscles, arising along with, or soon after the beginning of, fever—either fixed, and passing into inflammatory swelling of some joint, or variable in intensity, and erratic—may be considered as eminently indicating the rheumatic nature of the fever. This we can easily ascertain, even in the case of mere rheumatism, provided that it be *fixed*, in a joint or joints. But it is less easy to find out the seat of rheumatic pain in some other parts, during the depressed state of the child by the general effects of a vehement fever. I beg you, therefore, to reflect upon all and every circumstance and acts of investigation I have pointed out to you in previous lectures, as helping to unravel the intricacy of fever in

a speechless child; and more particularly upon what I said of the diagnosis of each of the rheumatic local affections; observing quietly and from a distance, and then near, and changing postures and perform movements; all that will be most requisite in the case in question.

One might object, however,—How are we able to distinguish rheumatic pain, without swelling, from nervous pain or spasm? On this I will speak under the head of chronic rheumatism; here I will merely observe that local pain, arising suddenly in connection with fever, if it is not, or becomes not soon, inflammatory, with swelling or exudation, is very probably of the rheumatic character; and if it happens in a child, almost certainly so.

Although it is not always possible at once to ascertain the rheumatic nature of a fever, it is desirable that all the mentioned symptoms and circumstances together may lead you to suspect it to be so, that you may follow its course with a prepared mind, and watchful eye for all what usually happens in the course of rheumatic fever, or what already may be present in that case, but concealed under the weight of general febrile symptoms, always heavily affecting a little child.

Measles and small-pox, and any other fever, in the beginning, and for some time, may appear just like the rheumatic; wherefore, occasionally we are obliged to suspend diagnosis, or rectify our opinion by the further progress of the disease.

I think I must call your attention also to the particular resemblance which some cases of acute *miliary* tuberculosis have to rheumatic fever, when the disease at once attacks an apparently healthy child. I will on another occasion mention a case of the kind, in which during three days, I could only find signs of pleurodynia. These cases are certainly very rare, at least rare to one skilled in auscultating on children.

Other slower and more ambiguous forms of the tuberculous process, as they occur in adults, or after puberty, in which a slight fever and pains through the chest, like the rheumatic, are for some time the only salient symptoms, before the deposits are sufficient to cause corresponding signs to our ear. Such I have seldom met with in young children. In that age the deposits take place more rapidly; and the younger the child the more prominent a part is taken by the glands, contributing to make the case intelligible.

The *disposition* of children to rheumatic fever and local affections is very extensive, but in general not so considerable as to the acutest form, what I designated the acute general articular rheumatism. Nurslings, I find, have a preponderating disposition to intestinal rheumatism, and to rheumatic cough; between six and eighteen months, I have frequently seen the disposition to rheumatic earache. Children of a delicate constitution and tender skin are more subject to different forms of the disease in question than others, in particular if they are of the scrofulo-nervous habit; then, between five and twelve years, the disposition to rheumatism of the eye is not uncommon in them. Those that have been overdrugged with mercury I observed to be par-

ticularly obnoxious to rheumatic affections of joints, though not of the acute form. Pleurodynia and rheumatic cough frequently occur in all ages of childhood. On the contrary, I find they are not disposed to endocardial rheumatism; at least, according to what I have seen, it can be but of rare occurrence in the first years of life. This fact, and the analogous one, concerning the acute general articular form, may perhaps concert in some way to advance the pathological knowledge of the rheumatic dyscrasy. The disposition once acquired may last for years and years. In some children, however, it ceases entirely as they grow older and stronger towards puberty. In some others, of course, there is no trace of it.

As the *cause*, everybody recognises a sudden change from warm to cold, particularly when the skin is perspiring and damp, cold more than dry. The sudden occurrence of east winds is also very productive of rheumatism. According to this property some countries represent a more fertile soil for this malady. In this respect there may be few countries worse than Hungary and Austria. England, particularly the eastern parts, enjoys also the discredit of being much troubled with rheumatism.

But, it cannot be denied, the mentioned changes of temperature are, as well, productive of catarrhal and parenchymatous inflammations. There must, therefore, be another condition or circumstance besides, special in producing rheumatism instead of pneumonia or catarrh. The electric influence, I believe, is too little known and valued in this respect. I remember many children who, without being exposed to cold, before stormy weather, or some other sudden change of the weather, became affected with rheumatism; and some even when confined to bed, and guarded carefully against "taking cold."

As a *prophylactic* measure, nothing is more proper than to accustom children, judiciously and by degrees, to the vicissitudes of temperature; performing cold sponging of their whole body, strengthening the more obnoxious kind of skin by lotions of a mixture of brandy and water. The custom to dress children lightly, with bare neck, short stockings, and trousers, as a general measure, is also very suitable, in constitutions which allow it.

Amongst *complications*, like as in adults, the rheumatic affections frequently combines with the bilious, the catarrhal, and others; the liability of children to rheumatism during the last stage of, or convalescence from, measles, is, however, very striking. But rheumatism combines also occasionally with other eruptive fevers.

The combination of intermittent fever with rheumatism is, I find, interesting. I have had to attend, at Pesth, many children at once affected with both diseases. The latter was only rheumatgia, more commonly costal pleurodynia, or rheumatic cough, always remittent or even intermittent, and increasing along with the paroxysm. I do not remember one single case in which pleurodynia, or articular rheumatism, when complicating ague, would have passed into inflammation, swelling, or exudation; nor do I know a

single case of genuine inflammation complicating ague. Now let me add to this that I did not see phlegmonous or parenchymatous inflammations, *f. e.*, pneumonia, suppurative pleurisy, acute meningitis with *plastic* or *purulent products*, in connection with an unequivocally-established rheumatic fever, not even with the acutest articular form, which we generally look at as inflammatory, and in which, no doubt, certain degrees and kinds of inflammatory action take place. These are, I believe, facts of some pathological interest. The remissions of the rheumatic fever come sometimes near the intermissions of ague. It stands between the inflammatory and ague.

The most frequent combination of local rheumatism is that with inflammation; thence a modification of the inflammatory process and its products arises, which is not sufficiently studied yet. I have seen only one or two cases of acute arthritis in the knee pass into suppuration; and even in these cases I could not state with confidence that it was originally rheumatism.

An intimate amalgamation of the rheumatic inflammation with the scrofulous dyscrasy, is a common and occasionally sad occurrence in childhood.

Those that have penetrated a little deeper into the difficulties of children's practice, and those of you who intend to do so, will perhaps excuse the minuteness and length with which I have dwelt on the subjects of this lecture. There are some obvious things which it is still suitable to call to mind in various practical connections. I will next speak of the treatment.

ON THE TREATMENT OF CHOLERA

BY CALOMEL AND COLOCYNTH.

By JOHN JONES, M.R.C.S., ENG., DERBY.

WHATEVER may be the nature of the poison which produces this terrible pestilence, or by whatever laws it traverses various regions, countries, and districts, and propagates its pestiferous influence, its primary action is, doubtless, on the nervous and vascular systems; but whether these are simultaneously affected, or in succession, is uncertain. Nervous depression, speedily followed by vascular congestions, particularly of the large veins of the abdominal viscera, seems to constitute the first stage. From the peculiar nature of the choleraic poison, of which nothing certain is known, the important functions of absorption and secretion become suspended, and in some organs altogether stopped. The mucous membrane of the intestinal tube throughout seems to be deprived of its usual secreting and absorbing functions, the mouth and fauces are no longer supplied with their natural moisture, and unquenchable thirst is the consequence. The mucous secretion of the stomach, and of the large and small intestines, is suspended, and seems superseded by a frightful exudation or effusion of the serum of the blood, constituting the copious watery evacuations, both by vomiting and purging, which for the most part are so characteristic of the

disease; mixed with these is, probably, the chyle, which the lacteals, deprived of their natural function, are unable to absorb, giving the evacuations the peculiar and characteristic appearance of rice-water. The liver ceases to secrete bile; for although in *post-mortem* examinations bile has been found in the gall-bladder, none flows into the duodenum. The kidneys secrete no urine, none being found in the bladder, which is usually contracted and empty.

The blood, deprived of its serum, has generally been found to be "black, or dark-coloured, not unlike tar in its consistence, thick, ropy, and semi-coagulated." This state of the blood, together with congestion of the lungs, preventing the usual oxygenation of the blood, sufficiently accounts for the blue colour of the skin, which in some fatal cases becomes nearly black. Arising from defective oxygenation of the blood, and impeding secreting functions, occurs also the reduced temperature, which is so remarkable as to cause the surface of the body to feel as cold as marble, and even the tongue and breath to feel cold.

The symptoms indicating amendment arise from the restoration of the absorbing and secreting functions of the abdominal viscera. Thus the appearance of bile and feculency in the alvine dejections are the harbingers of safety. Simultaneously with this gratifying occurrence, the symptoms of collapse disappear; the characteristic, watery, and light-coloured evacuations become gradually less liquid, frequent, and abundant; cramps subside; thirst is no longer urgent; the pulse rises; the temperature of the skin is restored, accompanied with a warm perspiration; the renal secretions are resumed, and for the first time from the commencement of the attack, micturition occurs.

The same causes which predispose to the production and spread of typhus fever, are also powerful in the production of cholera, when that peculiar and mysterious agency on which it more immediately depends, exists in the atmosphere. These are:—

1. Constitutional peculiarity, which renders some persons naturally more susceptible of the disease than others.

2. Great bodily fatigue, or mental depression.

3. Defective nutrition, arising either from want of nourishment, or from impaired digestion, by which due assimilation of the blood is prevented.

4. A vitiated state of the air, produced by exhalations from putrid animal and vegetable matters, abundantly generated by local nuisances, such as open cess-vaults, pigsties, slaughter-houses, &c.; badly ventilated houses, such as are generally occupied by the poor in back streets, courts, and alleys, and are often found built back to back, as if on purpose to prevent free circulation of the air; filthy, crowded, and badly-ventilated apartments, in which the inhabitants are constantly breathing the noxious air arising from their own lungs in respiration, rendered still more noxious by want of personal cleanliness.

In proportion as individuals have been exposed to the above predisposing causes of the disease during the

prevalence of epidemic cholera, will be their liability to become affected.

In the autumn of 1849 the inhabitants of Derby were thrown into great consternation by a visitation of cholera. In anticipation of its approach, every preparation was made to check its progress, and restrain its ravages. On its arrival the town was divided into districts, and a resident medical practitioner was appointed by the Board of Guardians to undertake the medical treatment of all cases which might occur amongst the poor in his district, and that there might not be unnecessary delay in the treatment, brandy, or whatever else might be required, was obtained by a written order from the medical attendant, addressed to any neighbouring shop, at the expense of the Guardians. This laudable plan was continued for about three weeks, but in consequence of the expense being thought too great, it was discontinued. In the district attended by my partner and myself, including several back streets and courts thickly inhabited by the poor, besides cases of dysentery, which was at the same time prevalent, *thirty-two* cholera cases were treated, and cured, who were affected with rice-water evacuations, together with cramps and symptoms of rapid exhaustion, some of whom were in a state of advanced collapse, with pulse hardly perceptible, surface cold as a corpse, breath and tongue cold, features shrunk, and marked blueness of the skin. The disease in nearly all the cases treated was preceded by neglected diarrhoea, which, after continuing for a few days, suddenly assumed the peculiar character of cholera.

Treatment.—The leading indication in the treatment of this fearful malady, is to restrain the escape of serum from the blood, on which its peculiar and fatal malignity depends. If this important indication can be fulfilled, speedy amendment is the consequence, if not, the progress of the disease becomes fearfully rapid, and certainly fatal, a few hours only deciding the momentous question whether it will terminate in death or recovery.

As diarrhoea usually precedes an attack of cholera, it becomes a matter of the utmost importance to distinguish between this state and actual cholera, in which it may or may not terminate; more particularly as the remedies which are found most appropriate in the one, are diametrically opposed to those which are found most efficient in the other. Chalk mixture, astringents, and opiates, which are so necessary and beneficial in diarrhoea, having no other effect than hastening the fatal catastrophe in cholera. Amongst the multitudinous remedies which have been recommended in the treatment of this fatal disease since its appearance in this country, those which are more or less purgative have been found most beneficial. Amongst these calomel has always been considered pre-eminent. This invaluable remedy in conjunction with the compound extract of colocynth I have found invariably successful, if administered sufficiently early, and before the occurrence of fatal collapse. The direct effect of this combination is to prevent the further escape of serum from the blood, by restoring the functions of the mucous

membrane of the alimentary canal, and in consequence, the functions of the abdominal viscera generally. Pereira, in his "Elements of Materia Medica," says:—"Colocynth, taken in small or moderate doses, acts as a very safe and useful purgative. Its operation is not limited to the acceleration of the vermicular movements, but is extended to the secreting and exhaling vessels of the alimentary canal, whose functions it promotes. Moreover, it stimulates the other abdominal organs, and after the absorption of its bitter acrid principle, it not unfrequently proves diuretic." "These remarks apply to the compound extract, the only preparation of colocynth of which I have personal experience. It would appear partly from observation in the human subject, and also from the experiments of Orfila on dogs, that colocynth is one of those purgatives which exert a specific stimulant influence over the large intestines."

My mode of treatment was as follows:—The abdomen and upper and lower extremities being first well rubbed with turpentine liniment, the patient was immediately wrapped in flannel steeped and wrung out with hot water, over which, and covering the whole body as if swaddled, was applied a warm dry blanket. This fomentation, &c., being repeated every two hours, two of the following pills were directed to be taken immediately, and one repeated every hour till the motions became feculent and more natural.—R. Chlorid. Hydrarg., gr. viij.; Extr. Colocynth. Comp., gr. xij; Ol. Carui, gtt. iij. M. Ft. Pil., viij. If the pills were rejected they were immediately repeated and occasionally accompanied with brandy or hot brandy and water.

Under this treatment a manifest amelioration of all the symptoms speedily occurred; the vomiting became less urgent; the alvine dejections instead of being more frequent as might, *a priori*, be expected as the effect of the purgative pills, becomes invariably less frequent, less copious, of greater consistency, and in a few hours feculent and mixed with bile. When these gratifying changes in the evacuations occurred, speedy and uninterrupted recovery usually followed.

The suddenness of the recovery of patients from being almost apparently in *articulo mortis*, was very remarkable, and in one instance was considered by the friends of the individual, who were "Mormonites or Latter-day Saints," an actual miracle, which they published in one of their tracts as a notable instance of the result of their prayers and laying on of hands! In some cases, however, after the cholera symptoms had subsided, slight fever occurred, which continued only for a few days.

It is a fact worthy of remark, that out of the thirty-two cases of cholera attended, eleven occurred on one side of Agard Street, besides nine cases of dysentery. This is a short street behind which a filthy brook runs, part of which is dammed up for the supply of mills and is generally stagnant; the remainder is very shallow and contains all kinds of noxious refuse. On the other side of the street, into part of which two large silks factories open, and the remainder is open to gardens, not a single case was reported.

When cholera first made its appearance in this country, Derby was not exempt from its visitation, but

compared with other towns its ravages were not great. More than half the cases reported, however, proved fatal. After the epidemic ceased solitary instances occasionally occurred, having all the peculiar characters of the Asiatic disease, which were equally rapid in their progress and fatal in their termination unless arrested by timely and appropriate treatment. Since its last visitation to Derby, in 1849, when its ravages were much greater than on the former occasion, solitary cases have also occurred, having so much the character of Asiatic cholera, that if the disease had at the same time appeared as an epidemic, they would without hesitation have been reported as such. I select the following out of eight cases which have been successfully treated by myself and partner, one of which occurred in October, 1850, a year after the epidemic had ceased, the other in August last.

Case 1.—Ann Jackson, aged 50, after having been affected with diarrhoea for three weeks, was suddenly seized on Monday morning, October 22, 1850, with vomiting, almost incessant purging, and cramps of the arms and legs. Motions passed involuntarily, thin, watery, and light coloured, resembling rice-water. Saw her at nine o'clock A.M., surrounded by her family, who were in deep distress on account of what they considered her hopeless condition, lying on her back, mouth half open; tongue furred and feeling cold to the touch; eyes sunk in their sockets; voice scarcely audible; nearly pulseless; skin of a dark colour and cold as a corpse. Although apparently in a complete state of collapse, she was perfectly sensible. The abdomen, arms and legs, were directed immediately to be rubbed with turpentine liniment and covered with flannels wrung out with hot water, and then to be wrapped or swaddled in a dry blanket. To be repeated every two hours.—R. Chlor. Hydrarg., gr. viij.; Extr. Colocynth. Comp., gr. xij; Sap. Ven., gr. v.; Ol. Carui, gtt. iij. M. Ft. Pil. viij. Two to be taken immediately, and one every hour till the motion becomes natural. Also to take every half hour brandy in sago.

5, P.M.—Is much warmer; has had no return of vomiting or purging, and cramps but very slightly.—Pergat.

Wednesday, 10 A.M.—Has taken the pills regularly, except when asleep; slept for several hours during the night; has had but one motion, not so thin or copious as they have been, but still white.—Pergat.

Thursday.—In much the same state as yesterday; has had a tolerable night; one or two motions (white); reaction fully developed; tongue dry, and much furred.—R. Liq. Ammon. Aciet., oz. ij.; Sp. Æth. Sulph. Comp., dr. iij.; Mist. Camph., oz. vss. M. Cap. oz. j., quartis horis. Pills to be repeated every two hours.

Friday.—Has had a good night, and this morning has passed several dark-coloured motions, and micturated for the first time since Sunday last.

Saturday.—Is much better in all respects; motions have become of a natural colour and consistency.—To take the pills once or twice a-day.

Monday.—Continues convalescent, and feels little more than general feebleness, from which she soon recovered.

Case 2.—Mr. Harvey, clerk of St. Werburgh's Church, aged 54, states that on rising in the morning of Monday, the 29th of August, he was affected with diarrhoea, accompanied with general lassitude, slight pain of the bowels, and faintness; motions very frequent, liquid, and copious. Had taken on the preceding night eel pie for supper, of which he says he eat very sparingly. The whole of Monday diarrhoea continued, with little abatement, for which he repeatedly took brandy. Tuesday morning he had a rhubarb draught, and occasionally took brandy; felt better, and walked about the town transacting business; in the afternoon motions much more frequent, copious, and liquid, with increased faintness. He continued occasionally to take brandy. About 11 o'clock, P.M., on getting out of bed, was seized with cramps of the arms and legs, fell down, and was unable to rise; whilst on the floor had a copious and involuntary motion, passed with great force, and he became extremely faint. On being lifted into bed I was immediately sent for. I found him greatly exhausted, affected with cramps of the upper and lower extremities, extending to the fingers and toes, and across the chest, excited and aggravated by the slightest movement. He had just vomited nearly half-a-potful of dark-coloured watery fluid; pulse full and slow; skin moderately warm, but of a darker colour than usual; eyes surrounded with a dark-coloured areola, and sunk in their sockets.

His feet were directed to be immediately placed in hot water and mustard; the abdomen and extremities to be rubbed with turpentine liniment, and afterwards a flannel, wrung out with hot water, to be applied; he was then wrapped round, as if swaddled, in a warm dry blanket. To be repeated every two hours. Two of the following pills were immediately given him, and one directed to be repeated every hour till natural motions were produced.—R. Chlor. Hydrarg., gr. viij.; Extr. Colocynth Comp., gr. xij.; Camph., gr. viij.; Ol. Carui., gr. iij. M. Fiat Pil. viij.

I remained with him till about five o'clock, and left him in an improved state, although during my stay he had frequently vomited copiously thin, clear, and liquid matters, and passed one or two motions, also copious, resembling milk-and-water, or rather the characteristic rice-water evacuations. Thirst was incessant and unquenchable. Cramps continued, but not so violent. About an hour after having left him, I was sent for in great haste, as the cramps had returned so severely that he thought he could not live; I found him, however, much better, although the cramps had been very severe, in consequence of getting out of bed. He was in a profuse perspiration; the change in the motions was more marked, less liquid, and not quite so white, although still abundant; cramp less severe; vomiting still copious, but not so frequent. The pills to be continued without the camphor, after which the vomiting ceased. In the course of the day (Wednesday) the

motions became more feculent, and slightly mixed with bile, accompanied with corresponding amendment.

Thursday.—Had a good night; motions much more natural, and for the first time since Tuesday has passed urine. The pills were omitted, and the following mixture substituted.—R. Pulv. Chlor., scr. ij.; Mag. Carb., dr. ss.; Mucil. Gum. Acacie, oz. ss.; Sp. Ammon. Arom., Tinct. Hyoscy. utr., dr. ij.; Aquæ Ment., oz. v. M. Cap. oz. j., bis terve die.

From this time convalescence became rapid, and on Saturday he left his room complaining of little more than weakness.

Total amount of calomel taken sixteen grains, and of compound extract of colocynth thirty-two grains.

October 9, 1852.

EXTRANEOUS SUBSTANCES IN THE EYE.

By AUGUSTIN PRICHARD, Esq., BRISTOL.

Read before the Bath and Bristol Branch of the Association, October 7, 1852.

THE detection and treatment of the symptoms produced by foreign bodies in the eye, are matters of considerable surgical interest, dependent upon the value of the organs implicated, the destructive results of inefficient surgical aid, and the thoroughly satisfactory cures obtained by the most simple measures. Besides this, the subject is a surgical curiosity. Having constantly under my care a number of these cases, I have for ten years past always examined with a microscope the minute bodies which I have removed from the surface of the eye, and as might perhaps be supposed, have met with a considerable variety.

It will perhaps make my paper more worthy of a scientific body like the present, if I first give some account of the numbers of accidents to the eyes, in proportion to the whole number admitted to an ophthalmic charity, of the per centage of accidents where a foreign substance still remains in the eye at the period of admission, of the numbers of the different kinds of substances found, and the occupation of the applicants. I will afterwards show to any who feel disposed to examine them, some of the objects I have prepared.

My observations are collected at the Bristol Dispensary for the cure of complaints in the eyes, founded by Mr. Estlin in 1812; and they go back as far as the year 1834, from which time the various injuries have been more distinctly arranged under their separate heads than they were before. This comprises a period of eighteen years, during the first part of which I attended the Eye Dispensary as pupil, and for the last ten years as surgeon.

Thirty-seven thousand one hundred and ninety-nine patients have been admitted during this time, that is about 2100 in every year, upon an average. 2856 of these cases were injuries to the eye, being between seven and eight in every hundred.

From this number of accidents we must take those that bear upon the present subject, and they are the following:—

	Per cent.	Of whole No. admitted.
1.—Injuries from lime	175 = 0.497	
2.—Pieces of iron or steel on the cornea	650 = 1.74	
3.—Other foreign substances ...	524 = 1.40	

I need not particularly describe the symptoms of an extraneous substance in the eye, as all have experienced the sensation, and must know that it leaves little room for doubt as to diagnosis. It must be remembered that the lid is the most sensitive part, and feels in the act of winking the foreign body stuck upon the globe of the eye, and the patient himself always refers to the upper eyelid as the position of the offending substance. The treatment is of course to remove it as speedily as possible, and for this purpose we ordinarily use a silver instrument, shaped like a cataract needle, considerably curved.

There are one or two observations I wish to make respecting the mein of a patient with an extraneous body in the eye. Some of the diseases of the eye are always accompanied by peculiar mein or characteristic gestures on the part of the patient. A child, with strumous ophthalmia, is brought into the room backwards, shrinking from the light, with both eyes screwed up as tightly as possible, with a handkerchief pressed up against them. A man with amaurosis walks in with his eyes widely staring and his brows raised, so as to prevent the possibility of any rays being intercepted in their progress to his insensitive retina. A patient with cataracts has his eyes partially closed, his brows contracted, and his hand raised to shade the eyes, to allow the iris to dilate as much as possible, and in a patient with an extraneous substance in the eye, one is entirely closed, or if opened for a moment is immediately closed again; he shows great incapacity of keeping his eyes open, which gives rise to the peculiar appearance of *intolerance of light with one eye only*, the other being in a great majority of cases quite sound. I have constantly noticed that the mein or general appearance of such a patient, and of the eye, (in a casual examination,) exactly resembles that of a man with *iritis*, which disease most commonly attacks one eye; and if inflammation has been produced by the extraneous substance, the redness is more like that in sclerotic inflammations than the colour of the eye in affections of the conjunctiva. There is another point of resemblance, which is one of particular physiological interest. It is commonly taught and believed that the optic nerve is the only afferent nerve to the third or motor nerve of the iris, *i. e.*, that the pupil contracts only when the optic nerve feels the impression of the light, and takes it back to the brain, sending the message to contract along the third nerve through the ciliary ganglion to the iris. Persons with an extraneous substance adherent to the cornea of one eye, almost invariably have that pupil more contracted than the other, notwithstanding the fact that the eye is kept more closed. The explanation of this is, that the fifth nerve distributed on the lids, feels the irritation and acts as an

afferent nerve to the iris, which immediately contracts. I sometime ago brought forward a proof of this fact, or of one exactly similar in nature, from the Blind Asylum Report. Two other instances have come under my notice recently. A girl completely blind from amaurosis after fever, and unable to distinguish the least light, was exposed to the rays of the sun. I saw the pupils of her eyes instantly contract, as in a seeing eye, and she said that she knew she was in the light from the sensation. With another blind person, whose eyes were completely sunk, and where there was no perception of the light, I performed the same experiment. She had no iris to contract, but she began to wink her eyelids and the tears began to flow from the weakness produced by a bright light, exactly as would happen in a seeing person exposed to the same influence. These facts prove beyond question that the fifth nerve *feels* the light and acts as an afferent nerve to the iris and eyelids as well as to the optic nerve.

I leave out of our present consideration all cases of accident, except where there have been extraneous substances adherent to the surface of the eye, and this is a tolerably numerous class, 1174 having presented themselves, amounting to one out of every thirty-one. I need scarcely say, that very few of these were women.

The artisans of a large city who most commonly come for aid on this account, are the following:—

Smiths, with scales of hot iron, which have struck upon the surface of the eye in hammering red-hot metal.

Stone-cutters, with minute portions of their chisels, or more rarely, of stone.

Millers, who have to chip the millstones, and thus also get struck with pieces of metal, or stone.

Millwrights, with pieces of steel on the cornea.

Boiler makers and engineers, as they call themselves, *i. e.*, engine makers, who are particularly liable to get pieces of iron in the eye, in chipping cast iron, or hammering the rust from old boilers, or in grinding.

Metal turners, as opticians' working men, &c., who are struck with minute points of brass or iron; these generally have thin pointed pieces, like the tip of a needle, driven into the eye, where they penetrate perpendicularly and adhere most firmly.

Carpenters, in hammering or grinding their tools.

Tilers and plasterers and masons, in building and breaking stones, and hammering the plaster from walls; or what is still more frequent, in driving the nails into the laths in their plastering business. The nails generally used are cast and cut by machine, and are extremely brittle.

We see from the country—

Colliers, from the numerous coal mines in the neighbourhood of Bristol, with pieces of coal in the eyes.

Farmers' labourers, who are injured in chopping trees, or hedging, or haymaking.

We must add to these, of course, all the little accidents that occur, as for instance in railway travelling or in a dusty road, which are entirely independent of the patient's employment, and may happen to any of us at any time.

I have encountered objects from the organic and inorganic world,—in fact, animal, vegetable, and mineral substances of various kinds, some one or two of each of which I should like to show you.

Of *vegetable tissues* there have been specimens of wood, in the form of chips, imbedded in the cornea, or under the lid; or minute pieces of bark, which have flown from the edge of the hatchet; portions of nut-shell, seeds, and grass. One specimen of hard woody structure shows the separate wood-cells very distinctly, but from what plant it comes I have not been able to determine.*

The *animal bodies* which I have had occasion to remove from the eye, have been minute flies, of various kinds, more or less entire, and the wing cases of insects,—that is, the hardened case or shell, in which are folded the inner or real wings of the coleopterous tribe of insects. They are concave on one side, and convex upon the other, and adhere very firmly to the cornea, in all probability with the action of the leather sucker by which boys raise stones,—i.e., by atmospheric pressure. An instance occurred in the year 1839, when the patient presented himself, after suffering pain and inflammation of the eye for ten months, and the removal of the wing-case relieved all the symptoms. There is sometimes a little difficulty in detaching them from the surface of the eye. Many of them are very pretty objects for microscopic examination, they are very minute, and I have removed several in an entire state.

Metallic substances.—Pieces of percussion caps,—of iron, brass, or copper, retain their metallic appearance, if they are *entirely* imbedded in the substance of the cornea, and are thus removed from the action of air and moisture, so that after removal they have the glistening appearance of a metallic surface; and in the case of iron, it is attracted by the magnet. Portions of percussion cap are generally more or less imbedded in the eyes, as the accident is always accompanied with considerable force. Pieces of lime and stone will adhere for some time to the cornea.

One of the most remarkable facts connected with these metallic bodies in the eye, is seen when a piece of iron is driven upon the surface of the cornea, and does not penetrate deeply, but is subjected at once to the double force of friction by the eyelid, and oxidation by exposure to the air and tears. If it remains a few days in the eye, an extraordinary change takes place in its form, for it assumes the shape of a minute iron ring, with a clear central hole. Of this curious fact I have numberless proofs in the shape of specimens, which I

have myself removed from the eye, and which I shall be happy to show you. Now, this ring is formed in two ways,—the small piece of iron adheres to the cornea, and the prominent part is gradually rubbed away by the lid until it becomes transparent in the centre, much as an optician grinds a concave lens; the other method is when the circumference of the minute piece of iron adheres as before, to the cornea, and the prominent centre is gradually loosened, and removed *en masse* by nature or art. Of the former of these methods—i.e., the gradual thinning of the minute point, I have proof in specimens showing all the stages until a clear ring is formed; and as to the latter, I have frequently removed with the silver curette, a central point, leaving a ring behind, which I have detached at once, or after a few days. These rings are frequently only oxide of iron, and not metallic iron, the occasional transparency showing that they are then no longer in the purely metallic state. I do not yet understand clearly why these pieces of iron are so generally circular as is the case; they either fly off from before the hammer hot and fused by the violence of the blow, or they are ground of a circular form between the lids and the globe of the eye.

IPECACUANHA AS A RESTORATIVE.

By JOHN HIGGINBOTTOM, F.R.S.

I AM induced to make some observations on the use of emetics, from what has been written on the case of the late lamented Duke of Wellington, in the last number of the *Provincial Medical and Surgical Journal*, page 516. It is there stated:—"Instead of a *depressing potion*, such as an emetic, to void a stomach which, at the utmost, could have little more than gas within it, stimulants, antacids, and sedatives, such as brandy, ammonia, castor, valerian, and opium, with mustard poultices and other rubefacients, or even vesicants externally, were indicated."

For many years I have been in the practice of prescribing an ipecacuanha emetic as a powerful restorative in some cases of exhaustion and sinking, and I read a paper on that subject, before the Nottingham Medico-Chirurgical Society, which was published in the *Lancet* for June 28, 1845.

I prescribe ipecacuanha in preference to any other emetic; for if given in a sufficient dose, as half a drachm of the powder, it produces full vomiting both safely and quickly; it has also the power of raising the system to its normal condition, without producing any unnatural excitement.

I have long discontinued in such cases the use of brandy, ammonia, and opium, considering them only as palliatives. I give the ipecacuanha if I know the stomach is empty, being convinced that the stimulus of vomiting rouses the sinking powers by producing a considerable effect upon the nervous system; that it equalizes the circulation of the blood, removes the

* One piece of vegetable cellular tissue went through a somewhat circuitous route, before it finally rested as one of my microscopic objects. A man presented himself with an acutely-inflamed eye, with puriform discharge, and on everting his upper lid, a foreign substance was seen, and removed, which turned out to be the cellular membrane of some vegetable. The history was this:—A few days before, he met and entered into conversation with a friend, (a butcher's boy), carrying a *bullock's punch* in his hand; from words they came to blows, and my patient was brought down by a heavy flap in the face from his adversary's disagreeable weapon. His eye was painful, and intolerant of light, from that time until the substance was removed, when it speedily recovered. The portion of vegetable matter, having escaped in the process of rumination and digestion, found its way thus abruptly into the man's eye, and thence into my possession.

vitiated secretions, and promotes the healthy secretions of the various organs of the body.

If ipecacuanha would have acted as an emetic in such a case as that of the late Mr. Huskinson, where the nervous system had maintained so great a shock, it might probably have had the effect of restoring the vital powers sufficiently to have admitted the operation of amputation. I consider the ipecacuanha so safe a remedy as an emetic, that I have given it in valvular disease of the heart, when the patient was suffering from indigestion.

Nottingham, October 7, 1852.

Proceedings of Societies.

BATH AND BRISTOL BRANCH.

A special general meeting of the Bath and Bristol Branch of the Association summoned in compliance with the unanimous resolution of the Council, was held at the Royal Western Hotel, Bristol, on Tuesday evening, October 27th, for the purpose of considering if any and what steps should be taken in consequence of the verdict given on the trial of *Bourn v. Cox*.

Mr. Norman, of Bath, presided on the occasion, and there were also present from the Bath District, Messrs. Bagshawe, John Barrett, Bartrum, Bush, Church, Cox, Cowan, James Crang, Finlater Crang, Davies, M.D., Evans, Mason, John Soden, Skeate, Stone, Tunstall, M.D., and Vicary; from the Bristol district Messrs. Coe, Colthurst, Clark, Cross, Budd, M.D., Bryant, Estlin, Godfrey, Green, Hinton, Lancaster, Leonard, Macey, Mayor, Morgan, O'Brien, M.D., Prichard, Sawyer, Smerdon, Symonds, M.D., Swayne, M.D., and H. Swayne. Messrs. Sugden of Westown, Field and Lawrence of Bath, attended as visitors.

Some preliminary objections taken by Mr. Cox, as to the presence of a reporter and the attendance of some gentlemen not members of the Association, having been satisfactorily disposed of,

Mr. COLTHURST, Honorary Secretary of the Bristol Branch, read the minutes of the quarterly meeting, held on the 7th of October.

The PRESIDENT then said,—Gentlemen, you have been called together at this special meeting, as the notice which has been addressed to you states, to consider if any and what steps should be taken in consequence of the verdict given on the trial, *Bourn v. Cox*; and also to consider the propriety of publishing such a letter on medical subjects as was recently done by Mr. John Barrett, in the case of *Bourn v. Cox*. The circumstances which have led to the calling of this meeting, as you are all aware, have arisen out of one of our members being concerned in a lawsuit, which was noticed in our *Journal*, and an invitation given to Mr. Cox to make some explanation about it. In the *Journal* of the 13th of September a letter was published from Mr. Cox,

and the Editor made some strong observations upon it, saying that this branch ought to take some steps in reference to the matter. Accordingly, one of our oldest members wrote to the Bristol Secretary, and suggested the calling together of the Council. They have met, and after a long and anxious consideration they thought the best step would be to call the whole branch together, well knowing that at such a meeting there would be that cool judgment and proper feeling of justice towards a fellow-member which, while it would uphold the honour and dignity of the profession, would also do justice to the gentleman concerned.

Mr. Cox: Mr. President, before the question is gone into, I would beg to make a few remarks. My letter has already been before every member of this Association, through the *Journal*; but I would beg in addition to add, if it were not sufficiently expressed in that letter, that I acknowledge that in my conduct in the affair against my patient Bourn, I was indiscreet and hasty in my proceedings. I appeal to those present whether I had not much provocation thereto. Further than this I am not prepared to acknowledge. I am come here to night, and if any man has to charge me with anything else, I am here prepared to answer it. I am not aware, that in this affair—indeed I know that I have done nothing that I am ashamed to look any man in the face for. I have already said that I have been indiscreet, and if I have done anything that ought to incur the censure of the profession, I know that here I shall have a fair tribunal before which to answer any charge. I know that I shall have fair play; I ask for no undue favour. I know that I may rely on fair play and good feeling from every member, and with that feeling I leave the case in the hands of this Association, and whatever sentence they may pronounce, I am ready to submit to it.

Mr. J. B. ESTLIN, of Bristol, said he felt bound to state briefly the reasons which induced him, unsolicited, and without consulting any one, to take the initiatory step which had led to the summoning of that meeting. He confessed that he felt in some degree disarmed, by the observations which had fallen from Mr. Cox, and hoped that nothing would be said by him out of that spirit of fairness which Mr. Cox had claimed. Having, however, received Mr. Cox's letter, and feeling that one of the members of the Association, in a court of justice, had been accused criminally, he might say, (because the accusation, though not one of perjury, was that of having procured a malicious arrest,) he felt that it was a matter which ought to be brought before this Society. He had heard from various quarters, that it was the desire of many of the members that the matter should be so brought forward, and this desire was expressed not only by those who took a view of the matter adverse to Mr. Cox, but also by those who thought he had been hardly used. He (the speaker) thought it was the duty of some one not belonging to the Bath Branch, to bring the matter forward, and have it canvassed, and therefore being one of the senior—he believed almost the oldest—member of the Bristol Branch, and feeling strongly the duty, as he advanced in life, to uphold the

respectability of the profession, not only for his own interest, but for the benefit of the junior members, he did not hesitate to send the letter on which the present meeting had been called. There was also another reason which weighed with him. At a former meeting the medical case was brought forward in a paper in which certain opinions were broached, but on which, interesting as they were, there was no discussion. A few days after that meeting he saw, in the Bristol papers, that a paper was read by Mr. Cox upon the question, with his opinions upon it; and that as no discussion took place, (he did not pretend to quote the exact words,) it was clearly left to be understood, that Mr. Cox's views on the subject were confirmed by the meeting. Now he looked on this as a false inference. Those who were present would not forget the silence which followed the reading of that paper, and which appeared to him to be an eloquent testimony of the Society to Mr. Cox's conduct. Thus it appeared to him that their Branch had been used to support certain views in favour of the defendant in the case of *Bourn v. Cox*. He (Mr. Estlin) was reluctant to speak at all on the present occasion, but it would be unfair in him not to allow that there were circumstances of great aggravation in this case. After a matter was passed, it was easy to say what was best to have been done, and this had induced him to view the matter with great indulgence. And he should rejoice if, in the course of this discussion, anything should occur to make Mr. Cox's conduct appear in a less unfavourable light, especially as he had now been induced to express his regret for the course he had taken. But, Sir, (continued Mr. Estlin,) we are very touchy about the successes of homeopaths, and hydropathists, and mesmerists, who take away our best patients, and probably those who are most remunerative; but they cannot take away our respectability—it is only by our own acts that we can lose our respectability. I must say that the trial at Bath, and the disgusting reports and comments which have appeared in the newspapers respecting it, have inflicted a wound upon the profession more deep and serious than all the professors of the novelties to which I have alluded have been able to effect. Sir, I did not think to take any other step than to bring forward the subject, but it may be necessary to have some specific resolution before the meeting, and therefore, having no personal feeling in the matter, I have no objection to read a motion, and to support it; I will do so, and will then leave the meeting to say whether it adopts the view which, after much reflection, I have come to. It is this:—"That it is inconsistent with the honour of the Association, to retain upon its list of members any individual against whom a verdict, casting a serious imputation on his professional conduct, has been recorded in one of her Majesty's courts of law, and that whereas Mr. W. A. Cox at present lies under this stigma, and has not taken any proceedings to reverse the verdict, he be requested to withdraw from the Association."

Dr. O'BRIEN suggested that the meeting should hear all that was to be said, before putting such a resolution.

The PRESIDENT: At present there is no question before us, and this resolution is put in to raise the discussion, but nothing can be done until it is seconded.

Dr. SYMONDS, (Bristol,) if Mr. Estlin saw no objection to a slight alteration, would second the motion, with a view to bringing the matter before the Society. Coming there, as he did, to hear the evidence to be brought before them, and having formed no strong opinion upon the subject, if Mr. Estlin had no objection, he would propose to alter the latter part of the resolution thus:—"That, whereas, Mr. W. A. Cox at present is under this stigma, and has not taken any proceedings to reverse the verdict, he be requested to declare whether it is his intention to take such proceedings, and if not, to show reason why he should not cease to be a member."

Mr. ESTLIN.—I am perfectly ready to adopt this as my resolution.

The PRESIDENT was about to put the resolution to the vote, when

Dr. O'BRIEN suggested that the Judge's summing up should be read, so as to bring the facts before all present.

After some observations from Mr. Godfrey (Bristol), Mr. Colthurst, and Mr. Clark (Bristol), the suggestion was not pressed, and

The PRESIDENT said, if no gentleman had any further observations to make he would put the resolution, and if it were carried he would then call on Mr. Cox for any statement he had to offer. The resolution having been put, and carried unanimously, the President continued:—"And now, Mr. Cox, I have to call on you for an answer to this distinct question. The meeting has now decided "that it is inconsistent with the honour of the Association to retain upon its list of members any individual against whom a verdict casting a serious imputation on his professional conduct has been recorded in one of her Majesty's courts of law; and that, whereas Mr. W. A. Cox at present lies under this stigma and has not taken any proceedings to reverse the verdict, he be requested to declare whether it is his intention to take such proceedings, and if not to show reason why he should not cease to be a member." I take it, that this resolution will become a precedent, and will be applicable in future to any member who may fall under its ban.

Mr. COX.—I assure you, Sir, that I am very pleased at having an opportunity of answering that question here before this Association. For I do feel, Sir, and I believe I shall be able to show you and this meeting that the verdict, which I do not admit to be one (as it has been alleged) of fraud, but whatever the verdict may have been, I say that it was arrived at by medical evidence that I challenge the medical witnesses here before a Jury that can understand their evidence to substantiate. I said that I did not admit that the verdict was one of fraud, and I ask gentlemen to consider, taking into account the strong remarks that were made by the Judge, that if I was guilty of what was charged against me it was one of the worst frauds that any member of society could be guilty of. The damages

were laid at £50; the verdict was for £15, the exact amount that was paid to me by the patient. And I leave it to you, that if the Jury thought it such a fraud as was laid before them by the Judge, whether they would not have assessed the damages at the full amount claimed. But upon what medical evidence was that verdict given? I say, that from first to last every one of the medical witnesses, from Mr. Topp to Mr. Bagshawe, did place the case so before the Jury as to lead them to suppose that such a case as I had sent in a bill for could not exist, or was most unlikely ever to have existed. Now, Sir, what was the case? A case of gonorrhœa of two months' standing, with stricture of the urethra, upon which supervenes syphilis and a bubo. That is the case, which I say the medical men led the Jury to believe was exceedingly improbable ever to have existed. I will proceed, Sir, in the first place, with the evidence of Mr. Topp, who was a druggist, and who swears he was for 22 years the apothecary at the Bath United Hospital. He was of opinion that "this was a very simple case; there were not the slightest symptoms of the disorders named by Mr. Cox in his bill. Witness considered that Mr. Cox's mode of treatment, as described in his bill, was most imprudent, and likely to be very injurious to the patient. The general opinion among medical men is, that the two diseases said to be cured by Mr. Cox cannot exist at the same time." This is the report of the proceedings in the County Court. I need not say that the report of the proceedings of county courts are not so accurate as those of the proceedings in assize courts. I shall therefore have to add from my own recollection and notes; and, as there are gentlemen here who were present at the trial, if I state anything incorrectly they will check me. I appeal to their recollection whether Mr. Topp did not lay down the opinion that gonorrhœa was a preventative of syphilis, and that a man could not have one with the other. Mr. Charles Alexander Harries follows Mr. Topp, and he had never observed the two diseases coexistent in the same patient. When he is examined by the Judge, he says the case professed to have been cured could not have been in five or six weeks, as stated; and then, in cross-examination, he says the case was very remarkable, if a real one, but no practitioner in France, England, or elsewhere, ever heard of such a case. If there were any doubt as to this statement having been made, it has been removed by Mr. Harries himself, since, on the Monday after the Saturday of the trial he went about inquiring of medical men—among others, of Mr. Barter—whether they had ever seen a case of gonorrhœa and syphilis coexistent. Mr. Barter replied, "Walk with me a hundred yards, and I will show you such a case." The next witness was Mr. Skeate. He said:—"I never knew a case in which the two diseases mentioned were coexistent together." I would do justice to the fairness with which Mr. Skeate gave his evidence against a brother professional man. It is no more than I should have expected from him, and I am sure the same bias which induced him to give evidence will now induce him to say that it was his opinion that the two diseases could

not coexist. I have seen him since, and he has most kindly lent me his assistance in this matter. But the last time he was still of opinion that the two diseases could not coexist. The next medical witness was Mr. Field, who saw no symptoms of Bourn's having taken large doses of mercury. My memory does not serve me here, but I believe Mr. Field did say, and I ask him now if he did not, that if Bourn had taken the doses of mercury he would have discovered it.

Mr. GODFREY: I don't think any question ought to be put to a stranger.

The PRESIDENT: I think you cannot put any question to Mr. Field.

Mr. Cox: I will waive that point, then, sir; but Mr. Field, when examined by the Judge, says he never saw a case with the symptoms described co-existing; and then in Mr. Field's manner, which is sometimes more forcible than his words, he says:—"It is possible, but in all my experience I never saw such a case." I am speaking of Mr. Field's manner in the presence of gentlemen who saw him examined, and who will understand my meaning. Then, Sir, Mr. Bartrum was examined. In other points he agreed with the other medical witnesses; but he testified to what is not reported, and his evidence was most strong as to my charge against my patient. He testified that where phimosis existed, a bougie could not be passed; and he gave as his reason that in phimosis there was inflammation of the glans. He also testified that a bougie could not be passed in the state in which I had charged for it in my bill. The next witness was Mr. Bagshawe. He said:—"I do not believe that the whole of the diseases mentioned existed at the same time." Now, if any doubt could exist as to the effect of this evidence, we have it removed by Mr. Bush and Mr. Barrett, who, upon hearing it came forward. They were neither of them, either directly or indirectly, asked by me to do so; but seeing that there was evidence before the Jury which they believed to be incorrect, they came forward generously and kindly to the rescue, and gave counteracting testimony. The main gist of their testimony was, that the two diseases could coexist, and that they had seen cases in their practice. If there is any further doubt, you have it removed by the summing up of the Judge, who said:—"As one witness after another was called, they all agreed," (I am quoting from the *Bath and Cheltenham Gazette*, of the 8th of September, 1852,) "As one witness after another was called, they all agreed that they did not believe that such a case ever existed and was treated in the same way. Their evidence, the Jury would see, took a duplex form: they did not believe that the diseases which were specified on the face of the bill ever could coexist in the same patient; and that, supposing the effects, and nature, and symptoms of the patient's case to be truly described, then they maintained that the treatment was incredible." Now, I say that this medical evidence was the evidence upon which the charge against me was founded; and the medical evidence being before the Court, other circumstances were made of importance which they would not other-

wise have had, and received a weight which would not otherwise have been given to them. I do not know that I am attaching greater weight than I ought to this medical evidence? But what were those other circumstances to which I have alluded? for here I shall not shrink from going into every circumstance of the case; and if I attempted to evade doing so, I know that I should not be allowed. I have said that I shall not shrink from going into every circumstance of the case, though there is only one other that I know of to which I need advert, and that is the interlineation of my day-book. I can only say that that day-book had been in the hands of my attorney before the trial: he had seen it, and examined every item; and I put it to him—for as I am not now before a court of law, but am here as before a court of honour, I will mention every circumstance. I said to him:—"Those charges where the interlineations are made, will they not be objected to if taken into the account?" He said, "Oh no, if they were made on the same day." The day-book was put in on the trial. It is here. I have offered any one in Bath to inspect it; and it is here now, open to any one for the purpose who pleases. The next matter was that a bill for £2. 6s. had been sent in to Bourn. Now, in Court that statement entirely failed, and I say that no bill was ever sent in. I don't say that Bourn, before he went away, was not under the impression that he knew something about the charges; and as I am not in a court of law, I will state upon what I believe that impression was founded. Bourn was about to go abroad, and I knew that I was liable to be called upon at a moment's notice for the charges against him. Accordingly as he had his medicine, whatever it was, it was written down on a scrap of paper to avoid having to be picked out from the day book. This piece of paper was in the possession of Mr. Lawrence's brother, but it was not filled up, and there was nothing on it but the mixtures and powders as they were had. The last time Bourn came he had a bottle of mixture, as stated in the bill, and whilst Mr. Lawrence's brother was entering it he looked over the paper, and so, I suppose, formed some rough estimate of what he would owe. On that rough estimate he went away, I believe, thinking that he owed me £2. 6s. I was, as I have stated, never applied to for a bill, and never told Bourn what my charge was, so that it was merely from a glance at the paper that he formed his estimate. This is a circumstance which could not be adduced in a court of law, but here you have it, and with it, I believe, the whole of the case. I believe, sir, that there is nothing else for me to touch upon; but if there may be any circumstance on which further explanation is desired I shall be only too happy to do so. I am not indifferent to the opinion of this meeting, or to anything they may think proper to do to me. I have been now for three months enduring a persecution which few medical men have ever had to endure. I have stood it, however, and I shall stand anything more that I may have to endure, for I know that whatever charges may be made against me in private or in public, I stand here ashamed to look no man in the face. I know that these things are

not ordered by man, but by a higher intelligence than man's; and this conviction which has hitherto supported me will continue to support me under whatever I may have to endure. I now leave my case with the meeting. I ask for no favour, and am very sure that at your hands, Sir, I shall have everything that is just.

The PRESIDENT: There is a portion of the resolution which you have not answered, Mr. Cox, and that is, whether you intend to take any proceedings to reverse the verdict.

Mr. Cox: The time is gone by for that. The law allows twelve days to apply for a new trial and those twelve days are gone by, the money is paid, and the thing is settled. But, if it were not so, I should not have recourse to other proceedings. I should be content to let the case rest where it is. I know too well the harass of law proceedings to involve myself in any further proceedings. With regard to the bill—I mean the form in which the bill was made out—I may state that the bill which was printed and published was a bill which was sent in by me on the application of the attorney for the plaintiff, and that it was not printed or published by me. My attorney, Mr. Slack, advised me to send it in as it is there set out, the better to give the patient's friends an opportunity of knowing what had been done. I admit that I thought it at last equivocal, but I took my attorney's advice in the matter, and I throw the responsibility on him, and he is willing to bear it.

Dr. O'BRIEN said that there was one point of great importance which Mr. Cox had not touched upon, and it appeared to be the main point—the charge of fraud, which was the essence of the whole affair. It appeared that certain entries had been interlineated, but it was not clear whether these entries were not made, as the Judge seemed to have intimated, to make the debt sufficiently large to arrest the patient.

Mr. Cox: With regard to that point, I have no hesitation in saying that if Bourn had come to pay me before he left, I should not have made the charges which I afterwards did. The Judge, in summing up, gave the profession this latitude. He says:—"Every medical gentleman was considered to have a very considerable latitude as to the amount of his charges against his patient. His own prudence and discretion, with due regard to his own interest, would keep him straight in this matter. Mr. Cox, in making out his bill, had a right to consider the willingness or unwillingness of the patient to pay."

Dr. O'BRIEN: The time of the entries is what I allude to.

Mr. Cox: With regard to the time, that can only be arrived at by an inspection of my day-book.

Dr. O'BRIEN: Can you state whether they were made day by day, or all at once to suit a purpose?

Mr. Cox: Day by day, as stated by me in Court on oath. They were made in a subsequent part of the day, after the operations were performed, and that is not an unusual thing, I believe, with medical men.

Dr. O'BRIEN: Is it Mr. Cox's constant practice to interline all cases of this description?

Mr. Cox : Not my constant, but my frequent practice. I would state again, that the bill was not distributed by me, but by the plaintiff's friends before going into Court, to prejudice the case.

The PRESIDENT : Has any gentleman any further observations to make. The question in the resolution has been asked of Mr. Cox, and he has answered it; and if there are any more questions to be put, I apprehend he is quite ready to answer them.

Dr. O'BRIEN : Is it admitted by Mr. Cox, that if the individual had paid in the ordinary way, he did not intend to charge for these operations?

Mr. Cox : Oh! no: not at all.

Dr. O'BRIEN : Then I want to know what the interlineations were made for?

Mr. Cox : They were made daily, as the operations were performed.

Mr. CLARK was of opinion, that although the charge of fraud was not made out against Mr. Cox, there was evidence to show his demand was exorbitant, and that he had been guilty of very great irregularity in making the interlineations in his book.

Mr. COLTHURST asked why the paper, which it was admitted Bourn had seen, and which had led him to expect that £2. 6s. was all he would have to pay, contained an account of the medicines only, and not the charges for attendance and operations which appeared in the day-book?

Mr. Cox : For this simple reason, that I should have charged for the operations in gross. It was on my mind when I went down to him on the evening of his departure to say:—"You are indebted to me for medicines so much," and I would have put it to him as to what he could have afforded to pay me for the operations. But when I was driven to make out my bill, I had to charge for every one separately. I believe, now, however, that it would have been more prudent if I had not done so.

Mr. JOHN BARRETT, in justice to Mr. Cox, would state that when Bourn saw the paper in question, he was under the impression that he owed £2. 3s. 6d.; that he had another mixture at that time which made up £2. 6s. 0d. Now, it appeared that altogether that he had thirty-nine mixtures, so that it required no great acquaintance with Cocker, to perceive that he must have owed something like double £2. 6s. 0d. Unless, therefore, they were prepared to say that these entries which were said to have been made *de die in diem* were all a forgery, and the price of the mixtures was to be at 2s. 6d. each, it was evident that the young man must have made a great mistake as to the amount he had to pay even for medicines. As to the operations, a young man whom he (Mr. Barrett) saw at the Court, named Biggs, who was a dispenser at the Eastern Dispensary, he believed had stated that Bourn had admitted to him that the bougie had been passed. With respect to the interlineations, he had already stated publicly that a fair examination of the book showed that Mr. Cox's statement could not be contradicted, for he found other similar entries in the same book, and he knew that he had done so also in

his own practice. How far it might be regular in a tradesmanlike point of view he did not know, but still their profession was but hybrid in this respect.

Dr. SYMONDS : I think Sir, in the first place, that this meeting is quite competent to consider a verdict given in a court of law. I know there are some who think otherwise, even where the case turns upon medical evidence; but I am of opinion that we, as members of a scientific profession, may very well question the justice of such verdicts. I think, moreover, that it is our duty, as a public body, to consider what is due to our respectability as a body, and to the interests of every medical brother. I think, also, Sir, that we are called upon to interpose, and to defend any member who may seem to us to have been harshly treated in a court of law. I am not prepared to say that that was the case with Mr. Cox, simply because I do not know how medical remuneration is charged in this kind of cases. There seems to me to have been two points put to the Jury; one, that he charged for treating two diseases which did not exist, but which he alleged to be coexistent, and for operations which could not have been performed; I presume this was the impression on the Judge and Jury. The second point was, that a bill had been dressed up in a particular manner, so as to give Mr. Cox a right to call for payment. Now, as to the first point, there was a conflict in the medical testimony; and Mr. Cox rests his defence on the question, whether the Judge and Jury gave sufficient attention to the difference of opinion which existed. On the other point, I think we should not be extreme to press Mr. Cox as to the amount of his charge. It is known that charges are, to a certain extent, indeterminate. We all know of cases where a person has been attended, and the practitioner having given a great deal of attention to the case, has said that having done all he could, he should yet not charge more than the amount of the medicines supplied. Now, supposing this was Mr. Cox's intention with regard to Bourn before he left Bath, he may have afterwards heard that he had left, settling all bills but his; and hearing this, he would naturally feel much aggrieved, and would say that whereas, before, he would only have charged for the medicines, and would have considered the visits and operations as acts of friendship or charity, now he would not remit the charge for all that was fully due. Now, if Mr. Cox could satisfy us that he had made such a reservation in his mind, and that the case was of that kind, I think we might very fairly take it into our consideration; and although there was certainly great haste on his part, and, as it seemed to me at first, harshness and almost cruelty, I say if all the circumstances were as I have put them suppositiously, we might deal with him with clemency, as well as with justice to our own respectability; and I should then consider it not expedient to enforce the resolution which I have seconded *pro forma*.

Mr. Cox : I did not exactly catch what has just fallen from Dr. Symonds.

Dr. SYMONDS : I wish to ask whether, in the first instance, it was intended to charge for the dressings and

operations, or whether they were merely considered gratuitous.

Mr. COX: They would have been charged, but I do not hesitate to say not to the amount, if Bourn had come to pay me in an honest way; and on this point I am justified by the Judge. He says, that in making out my bill I had a right to consider the willingness or unwillingness of the patient to pay; besides, Bourn was about to sail to Australia, owing me this amount of money, and when I came back I told his half-brother, whom I saw at the Commercial Rooms, that I would put him in possession of all the facts of the case, so that if he should hear any reports, he might know how far they were true. I did so, and although he felt annoyed at what had occurred, he said it served his brother right, for he had plenty of money, and he ought to have paid me.

Dr. DAVIS, (Bath): I very much agree with the view which Dr. Symonds has taken of this painful matter. It is quite clear that Mr. Cox has acted with great imprudence and precipitancy, but there is no evidence satisfactory to my mind that he acted at all with fraud; and therefore I think, that in our zeal for our own purity, we should act with some injustice if we included Mr. Cox under the preamble of that motion. I quite agree with that preamble, which is, "That it is inconsistent with the honour of the Association to retain upon its list of members any individual against whom a verdict, casting a serious imputation on his professional conduct has been recorded in one of her Majesty's courts of law." But I certainly think that in this matter there has been sufficient ground shown to make us pause before following up that preamble.

Dr. BUND (Bristol): Sir, I am sorry to be obliged to differ so entirely as I do from the two preceding speakers, for whose opinion I entertain the highest respect. I know how invidious these discussions are. I know how much more desirable it is to go on in a spirit of harmony. But sometimes associations like this have duties to perform: and stern duties. If we are bound by loyalty to our profession to lend our help and support to one of our members who has been aggrieved, and if we must not forget that we have duties to ourselves, I cannot on the other hand help feeling that we have also a duty to the public to perform. Now, I must confess that nothing has grieved me more than to hear from Mr. Cox his explanation of this painful case. I listened with eagerness to him, and, as he went along, I thought that a more distressing failure it had never been my lot to hear. We have called upon him to state why he has taken no proceedings to reverse this verdict, and we have heard his explanation. Now, for my own part, if such a verdict was recorded against me, casting such a foul stigma upon my professional character, I would have spent my last shilling or stripped my shirt from my back to assist me in procuring its reversal. We have asked him why he took no measures for this purpose, and his defence consists for the most part of the most cogent of all reasons why he should have taken such steps. For if he had the weight of medical testimony on his side, and the evidence

adduced against him was erroneous, he not only had the best of all reasons for proceeding but the most absolute assurance that he would have been successful in the attempt. Mr. Cox, however, says that it is now too late. Then, I say he must be allowed to suffer the consequences of his neglect. But, there is a fact which appears to have been lost sight of in the case, and that is that the medical evidence was not all on one side. Two respectable medical men were called for Mr. Cox. I say then, that Mr. Cox has failed in shewing any reason for not taking any steps to reverse this verdict, but he has shewn in the most striking manner that he had motives—paramount motives, for doing so. Will you state to us any palliating circumstances which should induce us to say,—Here is an exceptional case, not falling within the preamble of your resolution? For my part I think Mr. Cox has signally failed to make out that his is a such a case, I say, let any man take up this case and read it from end to end, with the bill appended to it, and then let him say whether Mr. Cox has given any adequate palliation for the course matters have taken in this distressing case. This, Sir, is the conclusion to which I have come, that the only course for this branch to take, not only for its honour but for its continuance, is this:—Mr. Cox having failed in showing any reason why he has not taken any proceedings to reverse the verdict, or to mention any palliating circumstances, the only course, I say, which remains, is to take steps to carry out the resolution which has been passed. These are my views, Sir, come to, I admit, very reluctantly. The matter is a painful one to deal with; but I feel that there is something in the times in which we live which behoves us to maintain the honour and dignity of the profession which we love. And, surrounded by charlatans as we are, with what face can we meet the public unless we keep up our respectability and see that our own hands are clean?

Mr. GODFREY, disagreeing with the view taken by the last speaker, moved "That the whole subject with regard to Mr. Cox be referred to the Council, with a request to them to report on it to the next quarterly meeting."

Dr. SYMONDS seconded this proposition, which, after a lengthened discussion, was carried in the affirmative.

The consideration of Dr. Swayne's motion, in reference to the publication of a letter by Mr. John Barrett respecting the case Bourn v. Cox, was also deferred till the next meeting.

Correspondence.

ON THE RELATIVE VALUE OF MATERNAL AND FETAL LIFE.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—I am very unwilling for you to think that I am dragging you unfairly into a discussion upon an opinion which you had a perfect right to express, in your review

of Professor Murphy's lectures. But I am sure you will permit me a few words in reply to your very courteous remarks upon my last letter. My opinion remains unaffected by your arguments, and I am still prepared to maintain that *any* "mother's life is 'infinitely' more valuable than her unborn child's." It seems to me to be one of those self-evident propositions which admits of no dispute or doubt whatever. It may, indeed, be admitted by any of us, if it could be acknowledged by one of the greatest men that ever lived, under most peculiar circumstances, and where there was every inducement, considering how an empire's destiny depended upon the preservation of the infant life, to sacrifice the maternal existence. When the Emperor Napoleon was told by the accoucheurs in attendance upon Maria Louise that they feared that they could not preserve the life of the Empress and that of the fœtus to which she was about to give birth, and asked him what course they should pursue under such momentous circumstances, he replied:—"Save both if possible, but at all events preserve the Empress." Memorable words, involving the utter destruction of his own and of a nation's hopes, from the most selfish being that ever existed. And well were they rewarded by the birth of the "King of Rome," and the safety likewise of the King of Rome's mother. I cannot help still believing that we are all of us addicted (especially in hospital practice) to set the same value upon the life of a fœtus as upon that of a parturient woman. There is a feeling of satisfaction, and a very proper one too, in having preserved the double life in a difficult and hazardous case. But do we not sometimes overstep the legitimate boundary of delay in our desire to obtain this satisfaction? How many a medical man, looking back upon his experience, can say of such and such a case, "I wish I had applied the forceps sooner," or, "I wish I had perforated at once, instead of hazarding the forceps; those women whom I so well remember, and whom I so often think of, would then have still been here."

You will answer to this that "numberless infantine lives are destroyed by undue interference with the perforator, or by the detachment of the placenta;" and you will yet further urge that "the laws of God and man alike tell us that we shall not kill, and we object to the breaking of those laws without some greater warrant than the mere accidental estimate of the value of the particular life involved." But to this style of argument it may not unjustly (and I hope not immorally) be observed, that the human law which forbids murder holds that there can be no murder without positive proof of the establishment of a *separate existence*. And touching the Divine law, I, for one, will never bring myself to believe that He who breathed into our nostrils the breath of life, will ever hereafter reproach any creature that he has made for having, from conscientious motives, stifled that flame which might have been fanned into a noble being, with a view of preserving the larger and more sacred life, whose continuity for a brief season longer would have ensured so much happiness to a family, a village, a city, or it may yet be—a world.

That can be no life (by comparison) which has never breathed;—that can be no death (by comparison) which

has only involved the sacrifice of the power of beginning a separate and independent life.

You will think, perhaps, that I am too bold in thus broaching, and venturing through your pages to promulgate, such a doctrine. It is truly one which our imperfect social system does not recognise, but which, if ever it is perfect, it will fully comprehend and appreciate. But when *some* professors of midwifery are compelled to talk of "murder," with a view of terrifying their readers into a proper estimate of the value of a fœtal life, it is time for others to lay down, as Dr. Murphy does, that "if we have any doubt about the mother's safety, we are not to hesitate one moment because of the child."

There are ever those who will be ready (I am far from saying that you are, Sir,) to take an ungenerous advantage of such a broadly-propounded doctrine, and attribute improper motives to its supporters. But, in spite of this, believe me the day will come when it will be entirely felt and acknowledged. So fully am I persuaded of it—so strongly am I convinced of the danger of that theory which admits every life to be of equal value, whether it be fœtal or adult, and which gives itself an adventitious colouring by the perversion of both Divine and human laws—that I would rather have to reproach myself with having been premature in the destruction of a fœtus in utero, to the amount of any number you like to mention, than with having sacrificed, through injudicious delay, for the remote chance of infantine preservation, *any* adult and maternal life. I can no more bring myself to believe that all lives are of equal importance, and that medical practitioners are not called to estimate and decide upon their relative importance, than that all men are alike gifted with the good things of this world, or that they are of the same mental or physical calibre. Therefore, can I never assent to a doctrine which teaches that it is murder to destroy a fœtus which has never breathed—which has not yet received the highest attribute of life, when such destruction is only carried into effect to protect and save from the chance of death one who is in a position to appreciate the goodness and acknowledge thankfully the mercies of Him who made us, and daily shields us all.

I am, Sir, your obedient Servant,

EDGAR SHEPPARD,

M.R.C.S. & L.S.A.

Enfield, Nov. 1, 1852.

P.S. It is a great satisfaction to me to state that I have received several letters from practitioners of many years' standing, expressing concurrence in the opinions expressed by me in the last number of your journal.

[Napoleon's order is so closely in accordance with our own sentiments and so opposed to Mr. Sheppard's, that we do not understand why he should be cited by him. But it is unnecessary for us to go over the ground already occupied, and we shall therefore content ourselves with protesting against our correspondent's estimate of fœtal life, merely reminding him that we have never held that the maternal and infant life are of the same value, but that it is necessary to be assured that one life or the other must be sacrificed, before determining to make the selection, which selection should be in favour of the mother.—ED. J.]

CASE OF A FEMALE WITH THREE BREASTS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Can you afford me a corner in our valuable and interesting journal, to record the case of a third mamma which has recently come under my observation. The young lady who is the subject of this singular *usus nature*, was confined several months ago, and a day or two afterwards called my attention to the circumstance. I found, besides the two ordinary mammae, a third, with clearly developed glandular structure, and distinct nipple, with darkened areola. On elongating the nipple, milk, of the same consistence and colour as from the other breasts, flowed from the lacteal vessels. On making reference I find that several interesting cases of the above description, one or two having four distinct mammae, are recorded in Dr. Davis's elaborate work on "Obstetric Medicine."

Yours most obediently,

R. MANNERS MANN,

M.R.C.S., Etc., &c.

Manchester, October 27, 1852.

CORRIGENDA IN OUR LONDON CORRESPONDENCE.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In your report of the first meeting of the Medical Society of London, published in your (yesterday's) journal, you record some observations made by me, on exhibiting to the Society an enlarged spleen. Your correspondent, however, has made two or three mistakes in this part of his report, which you will, perhaps, be so kind as to correct in your next impression. The required corrections are as follows:—

1st. Report says, "that deceased had been ill several weeks." This should read several *months*.

2nd. It is stated that the "nature" of the tumour in the abdomen "had not been recognised" (during life.) This is gratuitous; I did not say so.

3rd. I am made to give an opinion, that the compensating increase of one organ in size, &c., when its fellow is atrophied, "rarely, if ever, occurs after the 30th year." In this instance the words "thirtieth year" should be, *middle period of life*.

I am particularly anxious that this last error should be rectified, because I am quite sure that the compensating process to which I referred, often does happen later than the 30th year, or even up to the 40th year, after which it is, as I believe, of very rare occurrence.

I remain, Sir, very truly yours,

B. W. RICHARDSON.

Mortlake, London, October 28, 1852.

MR. COX'S CASE.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Will you permit us, through the medium of your journal, to request our medical brethren to suspend their judgment on the evidence given by us in the above case, until the report of the Council is before the profession. It will then be seen that we have acted with "honour and integrity," and that we have not "attempted to crush a professional brother" by giving erroneous medical evidence against him before a Jury composed of a major in the army, two retired medical men, an influential brewer, and a landed proprietor, all residing out of the city.

We are, Sir, your obedient Servants,

FREDERICK FIELD,
JOHN S. BARTRUM,
CHAS. ALEX. HARRIES,
EDWIN SKEATE.
EDMUND L. BAGSHAW.

DRAFT BILL,

(As Amended by the Committee.)

"TO PRODUCE UNIFORMITY OF MEDICAL EDUCATION AND QUALIFICATION, AND FOR THE REGISTRATION OF THOSE LICENSED TO PRACTISE IN MEDICINE."

PREAMBLE.—Whereas it is for the good of all Her Majesty's subjects that the knowledge of physic and surgery should be promoted, and that means should be afforded whereby those who have been examined and found skilful by competent authority may be known from ignorant and unskilful pretenders to the same knowledge: And, whereas the laws now in force concerning the profession of physic and surgery require to be amended: Be it enacted, by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by authority of the same:

I. *Repeal of Statutes.*—[3 Hen. 8, c. 11.]—That an Act passed in the third year of the reign of King Henry the Eighth, intituled, "An Act for the appointing Physicians and Surgeons;" and also
5 Hen. 8, c. 6. another Act passed in the fifth year of the same reign, intituled "An Act concerning Surgeons to be discharged of Quests and other Things; and also two
32 Hen. 8, c. 40. Acts passed in the thirty-second year of the same reign, respectively intituled, "For Physicians and their Privilege," and "For Barbers and Surgeons;" and also another Act
32 Hen. 8, c. 42.
33 & 34 Hen. 8, c. 8. passed in the Session of Parliament holden in the thirty-third and thirty-fourth years of the same reign, intituled, "A Bill that Persons, being no common Surgeons, may minister Medicines, notwithstanding the Statute;" and another

1 *Mary, Sess. 2,* Act passed in the first year of
c. 9. the reign of Queen Mary, intituled
 6 & 7 *Wm. 3,* "An Act touching the Corporation
c. 4. of Physicians in London;" and
 also an Act passed in the Session
 of Parliament holden in the sixth
 and seventh years of the reign
 of King William the Third, intituled, "An Act for
 exempting Apothecaries from serving the offices of
 Constable, Scavenger, and other Parish and Ward
 offices, and from serving on Juries;" and so much of
 every other Act as continues the last recited Act; and
 also an Act passed in the tenth
 10 *Geo. 1, c. 20.* year of the reign of King George
 the First, intituled, "An Act for
 the better viewing, searching, and examining of all
 Drugs, Medicines, Waters, Oils, Compositions, used
 or to be used for Medicines, in all places where the
 same shall be exposed for Sale, or kept for that purpose,
 within the City of London or Suburbs thereof, or
 within seven miles circuit of the said City" and so
 much of another Act passed in the
 18 *Geo. 2, c. 15.* eighteenth year of the reign of
 King George the Second, intituled,
 "An Act for making the Surgeons of London and the
 Barbers of London two separate and distinct Corpora-
 tions," as does not relate to the separation of the said
 corporations, or to the master, governors, and com-
 monalty of the mystery of barbers of London; and
 also so much of an Act passed in the
 55 *Geo. 3, c. 194.* fifty-fifth year of the reign of King
 George the Third, intituled, "An
 Act for better regulating the Practice of Apothecaries
 throughout England and Wales," as relates to the
 examination of apothecaries, or to the qualifications of
 persons intended to be examined or to qualify them-
 selves under that Act to practice as an apothecary, or
 to the fees to be paid by apothecaries for the certificate
 of the Court of Examiners, or to the penalties for
 practising as an apothecary without having obtained
 such certificate; and also so much
 6 *Geo. 4, c. 50,* of an Act passed in the sixth year
s. 2. of the reign of King George the
 Fourth as enacts, that all members
 and licentiates of the Royal College of Physicians in
 London actually practising; all surgeons being members
 of the Royal Colleges of Surgeons in London, Edin-
 burgh, or Dublin, and actually practising; all apothec-
 aries certified by the Court of Examiners of the
 Apothecaries' Company, and actually practising, shall be
 freed and exempt from being returned, and from serving
 upon any juries or inquests whatsoever, and shall not
 be inserted in the lists to be prepared by virtue of that
 Act, shall be repealed and annulled.

II. *Interpretation Clause.*—That the words following
 shall have the signification hereby given to them, unless
 there be anything in the context repugnant to such
 signification:—"Medicine" to signify "Medicine,
 Surgery, Midwifery, and Pharmacy;" "Medical" to
 include "Surgical;" "Council" and "Councils" to
 signify severally the Medical Council or Medical Coun-
 cils constituted under this Act.

III. *Appointment of the Medical Council for
 England.*—That a Council shall be established, which

shall be styled—"The Medical Council for England;"
 and that the Regius Professor of Medicine in the
 University of Oxford, the Regius Professor of Physic
 in the University of Cambridge, such one person as
 shall be from time to time designated by the Senate of
 the University of London, the President of the Royal
 College of Physicians of England, and the President of
 the Royal College of Surgeons of England, shall be
 members of the said Council in right of their several
 offices and appointments; and that the other members
 of the said Council shall be five Physicians, to be chosen
 by the Royal College of Physicians of England, five
 Surgeons, to be chosen by the Royal College of
 Surgeons of England, and six medical practitioners, to
 be appointed by one of Her Majesty's principal
 Secretaries of State; each of the said appointments to
 be made within three months after the passing of this
 Act; and the powers and duties vested in the said
 Council by this Act, may be exercised and executed by
 any six members thereof.

IV. *Tenure of Office by Members chosen by the
 Colleges.*—That every member of the said Council
 appointed by the said College of Physicians, the said
 College of Surgeons, and the said Secretary of State
 shall be entitled to be a member of the said Council for
 three years, and shall then go out of office, but may
 forthwith be rechosen; and that upon every vacancy
 among the members of the said Council, appointed by
 the said College of Physicians, the said College of
 Surgeons, and the said Secretary of State, and their
 successors, the said College of Physicians, or the said
 College of Surgeons, or the said Secretary of State, as
 the case may be, shall appoint another person to supply
 such vacancy.

V. *Appointment of the Medical Council for Scotland.*
 —[To be inserted hereafter.]

VI. *Tenure of Office by Members of the Medical
 Council for Scotland.*—[To be inserted hereafter.]

VII. *Appointment of the Medical Council for
 Ireland.*—[To be inserted hereafter.]

VIII. *Tenure of Office by Members of the Medical
 Council for Ireland.*—[To be inserted hereafter.]

IX. *Expenses of the Members to be paid.*—That
 there shall be paid to the members of the said several
 Councils, such reasonable expenses incurred by the said
 members in performance of their duties under this Act,
 not exceeding three guineas for each attendance, and also
 such reasonable allowance for mileage as shall from
 time to time be allowed by the said several Councils.

X. *Each of the said Councils to elect a President
 and Vice-President.*—That the said Councils shall, as
 soon as may be after they shall have been appointed as
 hereinbefore provided, meet at the following places:—
 That is to say, the Council for England at the building
 of the Royal College of Physicians in London, the
 Council for Scotland at the building of the Royal College
 of Physicians at Edinburgh, and the Council for Ireland
 at the building of the King's and Queen's College of

Physicians in Ireland, and shall each of them elect one of their members to be their president, and another of their members to be their vice-president; and in all cases every question brought before any of the said Councils, shall be decided by a majority of votes (the president, or, in his absence, the vice-president, having a vote,) and in the event of an equality of votes, the president, or, in his absence, the vice-president, shall have an additional or casting vote.

XI. *Each of the Councils to appoint an Examining Board.*—That each of the said Councils shall, within three months after their first meeting, appoint such fit and proper persons, not being members of the said Councils, as the said Councils may severally choose to form an Examining Board for the purpose of carrying into effect the provisions of this Act; and every member of such Examining Board shall be paid such yearly salary as the Council by whom he shall have been appointed shall think fit, and shall hold office for such period as the said Council shall determine.

XII. *Provisions as to the appointment of a Treasurer, Registrar and Secretary, and of Clerks and Servants, and for the making of a Seal by each of the said Councils.*—That each of the said Councils shall, within a month after their first meeting, appoint a fit and proper person to be their Treasurer, and also another fit and proper person to be their Registrar and Secretary; and there shall be paid to each of such Treasurers and Registrars such yearly salary as the Council by whom he shall be appointed shall think fit; and each of the said Treasurers and Registrars shall be removable at the pleasure of the Council by whom he shall have been appointed; and each of the said Councils shall also, from time to time, appoint such clerks and servants as they may deem necessary for the purposes of this Act; and every person so appointed shall be removable at the pleasure of the Council by whom he shall have been appointed, and shall be paid such salary as the Council by whom he shall have been appointed shall think fit; and each of the said Councils shall cause to be made a seal for their use in the execution of this Act, and shall cause to be sealed or stamped therewith all licences granted or issued by them in pursuance of this Act, and all such licences and other documents purporting to be sealed or stamped with any such seal shall be received as *prima facie* evidence in all courts and places whatsoever.

XIII. *As to the Registration of Medical Practitioners in practice before the passing of this Act.*—That the Registrar of each of the said Councils shall, within thirty days after his appointment, and shall from time to time, till the first day of February, one thousand eight hundred and fifty-four, proceed to register, in books to be kept for that purpose, on payment of a fee of five shillings, the name and place of abode, together with a description of the testimonials of every physician, surgeon, and apothecary who shall apply to be registered, and who, prior to the first day of November, one thousand eight hundred and fifty-three, shall have taken a degree in medicine in any English, Irish, or Scotch University, or who shall state his place of abode and apply to be registered, and shall produce his diploma, certificate, or licence, or shall produce a duly attested certificate, or such other proof as shall be satisfactory

to the said Registrar, of his having obtained a diploma, certificate, or licence to practise as a physician, surgeon, or apothecary, dated prior to the said first day of November, one thousand eight hundred and fifty-two, and granted by any English, Irish, or Scotch College or Hall, or any Corporation, sole or aggregate, in England, Ireland, or Scotland, legally entitled to grant the same at the time of the passing of this Act; and also to every person who shall apply for the same, and who was actually practising medicine in England and Wales prior to the first day of August, one thousand eight hundred and fifteen, and who shall sign a declaration according to the form in Schedule A, to this Act annexed, and also to every surgeon and assistant-surgeon of the Army and Navy who shall apply for the same, and whose warrant of appointment bears date prior to the said first day of August, one thousand eight hundred and fifteen, and to every person who shall have been registered as aforesaid, the said Registrar shall give a certificate according to the form in Schedule C, to this Act annexed, and which certificate shall be in force till the first day of February, one thousand eight hundred and fifty-four, and no longer.

XIV. *Every Person not Registered as aforesaid to present himself before the Council of his country for Examination. Licences to be granted to those duly qualified on payment of a Fee of £5.*—That each of the said Councils shall meet at least once in every three months for the dispatch of business; and every person not being registered under the provisions of the next preceding section of this Act, or not being a graduate in medicine, or a licentiate in medicine, of one of the Universities of Oxford and Cambridge, who intends to practise medicine after the first day of February, one thousand eight hundred and fifty-four, shall present himself before the Council for the country in which he intends to practise; and if such Council shall consider the person so presenting himself to be properly qualified as hereinafter is mentioned, they shall direct their Registrar to grant to such person a licence according to the form in Schedule B, to this Act annexed, on payment of a fee of five pounds; and every person to whom such licence shall have been granted as aforesaid, shall be entitled to assume the name and title of a Licentiate in Medicine.

XV. *Candidates for Licences to produce Testimonials to the Council.*—That every person who may present himself before any of the said Councils for the purpose of obtaining a licence in medicine, shall produce proofs to the said Council that he has attained the age of twenty-one years, and shall also produce such testimonials as shall be satisfactory to the said Council, that he has passed at least four years in some university or medical school approved of by the said Council, unless he shall have been a pupil to a registered medical practitioner for at least two years, in which case he shall have passed at least three years in such university or medical school; and that he has attended such courses of dissection, such clinical and other lectures, and such hospital practice, and has passed such several examinations before the Examining Board appointed by the said Council, as the said Council shall from time to time appoint.

XVI. *Triennial Medical Congress to be held.*—That

once in every three years each of the said Councils shall depute three of their members to form a Medical Congress, for the purpose of fixing a uniform curriculum of study, in accordance with the next preceding section of this Act, to be gone through by all candidates for licenses to be granted by the said Councils respectively; and such Medical Congress shall meet in London at such place and time as the Council for England shall determine; the first Medical Congress to be held as soon as may be after the election of the said several Councils.

XVII.—*As to Registration of Medical Practitioners who shall not have been Registered under the Thirteenth Section of this Act.*—That the Registrar of each of the said Councils shall, on and after the first day of —, one thousand eight hundred and fifty—, proceed to register, in books to be kept for that purpose, and without any payment whatever, the name and place of abode, together with a description of the testimonials of every physician and surgeon who shall apply to be registered, and who shall produce the diploma or licence to practise in medicine of either of the Universities of Oxford and Cambridge; or who shall produce the diploma or licence of the Royal College of Physicians, or the diploma or licence of the Royal College of Surgeons, of the country in which he applies to be registered, together with the licence of the Council for the same country; or who, in Scotland, shall produce the diploma or licence of the Faculty of Physicians and Surgeons of Glasgow, together with the licence of the Council for Scotland; and to every person who shall have been registered as aforesaid the said Registrar shall give a certificate, according to the form in schedule C, to this Act annexed, and which certificate shall be in force until the first day of February then next ensuing, and no longer.

XVIII.—*Registrars to Issue Annual Certificates to Registered Practitioners, on payment of a fee of 5s.*—That the Registrar of each of the said Councils shall from time to time issue a certificate, according to the form in schedule C, to this act annexed, to every person who shall be registered as aforesaid, and who shall apply for such certificate; and the said Registrars shall issue such certificates for the countries only for which they shall be severally appointed to act; and every person shall, upon his application for such certificate, pay to the Registrar a fee of five shillings; and such certificate shall bear date on the first day of February then next ensuing, and shall continue in force during one year and no longer.

XIX.—*All monies received by the Registrars to be applied for the purposes of the Act.*—That all monies received by the Registrars of the said several Councils shall be paid over to the Treasurers of the said several Councils, and shall be applied to defray the expenses of carrying this Act into execution, in such manner as the said Council shall direct; and if, after paying such expenses, any surplus shall remain in the hands of the Treasurer of the said Councils, such surplus shall be yearly applied for the founding or establishing of medical scholarships or prizes, or in promoting the advance of medical science and literature, in such manner as such Council shall determine.

XX. *Annual Statement of Income and Expenditure.*

—That each of the said Councils shall, once in every year, publish a full account of their income and expenditure for the year then last past, and shall cause their Secretary to transmit a copy of such account to one of Her Majesty's Principal Secretaries of State.

XXI. *Each Registrar to keep a Record of Certificates.*—That the Registrar of each of the said Councils shall duly record an account of every certificate which he shall issue as aforesaid; and in the month of February in every year shall cause to be printed a correct register, in two lists, according to the form in schedule D, to this Act annexed, of the names and places of residence, arranged alphabetically, in each list, of all persons to whom he shall have so issued certificates during the year then last past, according to the provisions of this Act, together with a description of the legal qualification or qualifications, with the date or dates thereof, of all persons registered under the thirteenth section of this Act, and specifying the date of the licence granted by the Council, and the degrees and diplomas with the date or dates thereof, possessed by all persons registered under the seventeenth section of this Act; and such registers shall be respectively called, "The Medical Register for England," "The Medical Register for Scotland," and "The Medical Register for Ireland;" and a printed copy of the Register for the time being, so published as aforesaid, shall be evidence in all courts, and before all Justices of the Peace and others, that the persons therein specified have obtained certificates according to the provisions of this Act; and the absence of the name of any person from such printed copy shall be evidence, until the contrary be made to appear, that such person has not obtained a certificate according to this Act.

XXII. *Registered Persons Entitled to practise where Certificates are Issued; and to transfer their Names to the Register of other parts of the United Kingdom.*—That every person who shall be registered, and shall possess a certificate in force, according to the provisions of this Act, shall be entitled to practise medicine throughout that part of the United Kingdom for which his certificate was issued; and every person who shall be registered in one part of the United Kingdom may transfer his name to the register of any other part of the United Kingdom in which he may be about to practise, on production to the Registrar of the last-named part of the United Kingdom of his licence and certificate for the current year; and the Registrar shall thereupon grant to such person transferring his name a certificate, which shall remain in force till the first day of February then next ensuing.

XXIII. *Registered Persons entitled to Charge for Advice and Visits.*—That all persons who shall be registered and possess certificates according to the provisions of this Act, shall be entitled to demand and recover in any court of law, with full costs of suit, reasonable charges for medical aid, advice, visits, and medicine, rendered or supplied by them to their patients, without any other licence than such registry and certificates.

XXIV. *None but Registered Persons to Recover Charges.*—That, after the first day of February, one thousand eight hundred and fifty-four, no person shall be entitled to recover any charge in any Court of Law

for any medical advice, attendance, or for the performance of any operation, or for any medicine prescribed, administered, or supplied by him, unless he shall prove upon the trial either that he is in possession of a certificate in force, according to the provisions of this Act, or that he was legally practising in the capacity in which he claims such charge at the time when the debt was incurred.

XXV. Persons not possessing Certificates Incapable of Acting as Medical Officers in Public and Other Situations.—That, after the first day of February, one thousand eight hundred and fifty-four, no person who does not possess a certificate in force, according to the provisions of this Act, shall be capable of holding any appointment in any part of the United Kingdom, in the capacity of a physician, surgeon, apothecary, or other medical officer, in any hospital, infirmary, dispensary, lunatic or other asylum, lying-in hospital, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse, or poorhouse, parish, union, or other public establishment, body or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age.

XXVI. Summary Penalty against Unregistered Practitioners.—That, if any person shall, after the first day of February one thousand eight hundred and fifty-four, act or practise as a physician, surgeon, apothecary, or licentiate in medicine, in any part of the United Kingdom, without being duly registered according to the provisions of this Act, and without having a certificate as aforesaid in force at the time of his so practising or acting as a physician, surgeon, apothecary, or licentiate in medicine, he shall, on conviction before any magistrate having jurisdiction in the county, city, or place where the offence was committed, forfeit and pay a sum not exceeding five pounds, nor less than forty shillings, for every such offence, to be recoverable within six months next after the commission of the said offence.

XXVII. Expulsion of Registered Practitioners for Disgraceful Conduct, or Irregular Practice.—That, if three registered practitioners shall at any time complain to the Council of any College or other governing body, that a person who had obtained his licence, diploma, or qualification from such College, or body, had been conducting himself in a manner calculated to bring scandal and odium on the profession, by publishing indecent advertisements or pamphlets, or immoral or obscene prints or books, or had been guilty of any other disgraceful and unprofessional behaviour, or of any irregular practice, the said Council, or other governing body aforesaid, are hereby empowered to cite the person accused before them, first giving him due notice, and a full statement of the charges against him; whereupon the said Council, or other body, having heard the defendant, and on being satisfied that the charges have been proved, or in default of his appearance, having decided that the charges have been proved, they are hereby required to erase the name of such person from the books or rolls of the said College, or other institution as the case may be, and shall transmit forthwith to the registrar of that part of the kingdom to which such College, or other institution belongs, an official report of their decision, authenticated by the

seal of such College; and the said Registrar shall thereupon strike out the name of the offending party from the register in his custody, and it shall ever afterwards be excluded from every register to be kept under the provisions of this Act, unless the Council, or other governing body by whom the name was first erased shall readmit it into the books or rolls of such College, or other institution. Provided always that the name of no person who may be possessed of a licence granted by a Medical Council according to the provisions of this Act, shall be erased from the register, unless the Registrar receive from such Medical Council an official decision to that effect, authenticated by their seal.

XXVIII. Penalty for the Wilful Falsification of the Record of Certificates by any Registrar.—That if any Registrar under this Act shall wilfully make or cause to be made any falsification in any matters relating to any register, certificate, or record aforesaid, every such offender shall be deemed guilty of a misdemeanor in England and Ireland, and in Scotland of a crime and offence; and shall, on conviction thereof, be sentenced to be imprisoned for any term not exceeding six months.

XXIX. Penalty for Obtaining Certificates by False Representations.—That if any person shall wilfully procure, or attempt to procure, a certificate from any Registrar, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing; or shall, by any false or fraudulent means whatsoever, possess, obtain, use, or attempt to possess, obtain, or use, any certificate as aforesaid, every such person so offending, and every person aiding and assisting him therein, shall, upon being convicted thereof, be adjudged guilty of a misdemeanor in England and Ireland, and in Scotland of a crime and offence; and thereupon it shall be lawful for the Court before whom such offender shall be tried and convicted, to sentence such offender to be imprisoned, with or without hard labour, for any period of time not exceeding six calendar months.

XXX. Penalty for Falsely Pretending to be a Medical Practitioner.—That every unregistered person who shall wilfully and falsely pretend to be, or take or use the name or title of a physician, doctor, bachelor of medicine, surgeon, or apothecary, or any name, title, addition, or description, implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or apothecary, or a practitioner in medicine, shall, on being convicted of every such offence, before any Magistrate having jurisdiction therein, pay a sum not exceeding twenty pounds, nor less than five, to be recoverable as hereinafter described.

XXXI. How Penalties are to be Recovered; if not paid, the Offender may be Committed.—That any Justice of the Peace acting in and for the county, city, or place in which the offence has been committed, or any Magistrate appointed by virtue of an Act passed in the second and third years of the reign of Her Majesty Queen Victoria, intitled "An Act for Regulating the Police Courts of the Metropolis," or one of the Justices of Peace Courts in Scotland, may hear and determine any complaint charging any person with practising medicine, without a certificate, as aforesaid, on the oath of one or more witnesses, or by the confession of the accused party, and shall award the penalty or punish-

ment herein provided for such offence; and in every case of the adjudication of a pecuniary penalty under this Act, and of non-payment thereof, it shall be lawful for the said Justice or Magistrate to commit the offender to any gaol or house of correction within his jurisdiction, for a term not exceeding one calendar month, when the sum does not exceed forty shillings, and for a term not exceeding six calendar months when the sum does not exceed twenty pounds, the imprisonment to cease on payment of the sum due.

XXXII. *Application of Penalties.*—That any sum or sums of money arising from conviction and recovery of penalties for offences committed against the authority and provisions of this Act, shall be paid to the Treasurer of the Council for that part of the United Kingdom in which such conviction shall take place.

XXXIII. *Examiners may take Candidates to Hospitals, &c.*—That each of the said Examining Boards, or any members or member thereof, shall be empowered to attend with the candidates for licences in the public hospitals, or other public institutions containing sick and diseased persons, and also in any workhouse, with the view of ascertaining the practical knowledge of such candidates in the science of medicine.

XXXIV. *Provision for existing Students.*—That it shall be lawful for the said several Councils to make regulations for dispensing with such provisions of this Act as to them shall seem fit, in favour of Medical Students who shall have commenced their professional studies before the passing of this Act.

XXXV. *Act not to affect the Trade or Business of Chemists and Druggists.*—That not anything in this Act contained shall extend, or be construed to extend, to prejudice or in any way affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing and vending, drugs, medicines, and medicinal compounds, wholesale or retail, without the giving of medical or surgical advice.

XXXVI. *Registered Medical Practitioners exempted from serving on Juries, Inquests, &c.*—That every person who shall be registered and possess a certificate in force, under the provisions of this Act, shall be exempt, if he shall so desire, from serving on all juries and inquests whatsoever, and from serving all corporate, parochial, ward, hundred, and township offices, and in the Militia; and that the name of such person shall not be returned in any list of persons liable to serve in the Militia, or in any such office as aforesaid; and no person shall be entitled to such exemption as aforesaid, on the ground of being a physician, surgeon, or apothecary, who does not possess such certificate then in force as aforesaid.

XXXVII. *For certain Offences, names of Medical Practitioners to be erased from the Register.*—That if any registered medical practitioner shall be convicted in England or Ireland of any felony, or in Scotland of any crime or offence inferring infamy, or the punishment of death or transportation, or if it shall be found, by the judgment of any competent Court, that any such medical practitioner shall have procured a certificate under this Act by any fraud or false pretence, or that any such medical practitioner has wilfully and knowingly given any false statement, evidence or certificate, in any case in which by law the evidence or certificate of a physician, surgeon, or apothecary is required, the

Registrar of each of the Councils, on the production before him of an office copy or extract of the conviction or judgment of the Court, duly certified under the hand of the proper officer of the Court, or other proof thereof, shall cause the name of such medical practitioner to be erased from the register; and every person who shall have been so erased after such conviction or judgment as aforesaid, shall thereby forfeit and lose all the privileges of a registered medical practitioner provided by this Act.

SCHEDULE A.

Declaration required of a person who claims to be registered as a medical practitioner upon the ground that he was in practice as a medical practitioner before the first day of August, 1815:—

To the Registrar of the Medical Council for England.

I, [Samuel Baker,] residing at [6, Duke Street, Exeter,] in the county of [Devon,] hereby declare that I was practising as a medical practitioner, at [16, George Street, Hastings,] in the county of [Sussex,] before the 1st day of August, 1815.

(Signed) [SAMUEL BAKER.]

Dated this [6th] day of [November,] 1852.

SCHEDULE B.

Licence in Medicine.

This is to certify that [Herbert Jones] has been carefully and deliberately examined as to his skill and abilities in the science and practice of medicine, and as to his fitness and qualification to practise the same, by the Examining Board appointed in pursuance of an Act of Parliament passed in the [] year of the reign of Her Majesty Queen Victoria, intituled "An Act to produce Uniformity of Medical Education and Qualification, and for the Registration of those Licensed to Practise in Medicine;" and the Medical Council for [England] have, by virtue of the powers vested in them by the said Act, directed this Licence to be granted to the said [Herbert Jones,] certifying that he is duly qualified to practise medicine.

(Signed) [JOHN FAIRBROTHER,]

President of the Medical Council for [England.]

(Signed) [HENRY BROWN,]

Registrar of the Medical Council for [England.]

Dated this [3rd] day of [March,] 185 .

SCHEDULE C.

The Medical Register for [England]—Medical Registration Certificate for 185 .

In accordance with the provisions of an Act of Parliament, passed in the [] year of the reign of Her Majesty Queen Victoria, intituled, "An Act to produce Uniformity of Medical Education and Qualification, and for the Registration of those Licensed to Practise in Medicine," I hereby certify that [James Howard,] residing at [No. 15, Ormond Street, Manchester,] in the county of [Lancaster,] (having been in practice prior to the first day of November, 185 , and having produced before me the [Diploma] of [the Royal College of Surgeons of England,] granted to him [April 11th, 1840,] as [a Member of that College,] or [some one of the Diplomats or Licenses specified in the thirteenth section of the said Act,]) or (having signed before me a Declaration according to the form in

Schedule A to the said Act annexed,) or (having produced before me the [Diploma] of [the Royal College of Physicians of England] granted to him the [6th] day of [March,] 185 , together with the Licence of the Medical Council for [England,] granted to him the [4th] day of [February,] 185 ,) he has been duly registered, according to the provisions of the said Act, as a person who is qualified to practise Medicine in any part of [England and Wales,] and that he is entitled to exercise all the powers and privileges conferred by the said Act.

This Certificate to remain in force until the 1st day of February, 185 , and no longer.

(Signed) [HENRY BROWN,]

Registrar of the Medical Council for [England.]

Dated this [1st] day of [February,] 185 .

SCHEDULE D.

The Medical Register for [England], consisting of the names and places of residence with a description of the qualifications and the dates thereof, of all persons legally qualified to practise medicine in [England,] in the year 185 .

The Names of Registered Medical Practitioners, arranged in two lists as Physicians and Surgeons.

PHYSICIANS.

(Arranged Alphabetically.)

NAMES.	Qualifications and their Dates.	Places of Residence.
ADDISON, JAMES	Diploma as a Fellow of the Royal College of Physicians of England, dated 9th August, 1836	No. 16, Tudor Street, Manchester.
ADLARD, HUGH	Diploma as a Graduate of the University of Edinburgh, dated 3rd April, 1845	No. 7, Milton Street, London.
ADNEY, RALPH	Diploma as a Member of the Royal College of Physicians of England, dated 2nd of May, 1854; Licence from the Medical Council for England, dated 5th July, 1855	The Grove, Camberwell.

SURGEONS.

(Arranged Alphabetically.)

NAMES.	Qualifications and their Dates.	Places of Residence.
ADPART, EDMD.	Diploma as a Fellow of the Royal College of Surgeons of England, dated 4th September, 1833	No. 40, Tolville Street, Leeds.
ADWIN, GILBERT	Declaration as required by Law, of having practised as a Medical Practitioner before the 1st day of August 1815	No. 19, Milcom Street, Manchester.
ANDREWS, JOHN	Licence of the Society of Apothecaries, London, dated 11th June, 1834	No. 8, Hilton Street, Liverpool.
APPLETON, WM.	Diploma as a Member of the Royal College of Surgeons of England, dated 2nd July, 1854; Licence from the Medical Council for England, dated 5th May, 1855	No. 80, George Street, Exeter.

Provincial Medical & Surgical Journal.

WEDNESDAY, NOVEMBER 10, 1852.

THE space occupied by the amended Bill, and the press of other matter, prevents our doing more at present than to draw attention to the chief alterations in the Bill so amended. It will be seen that an Interpretation Clause has been inserted, that a clause has been introduced providing for the publication of an annual statement of accounts, that an alteration has been made in the fifteenth clause in favour of the pupils of registered practitioners, and that the Provident Fund has been entirely done away with.

These important alterations, with some others of less consequence, are in accordance with the suggestions made at a majority of the Branch meetings, and by private individuals; in our next number we shall notice the subject, and hope in the meantime to receive communications from those interested in the question. At the last meeting of the Committee two deputations were appointed, one to confer with the Scottish authorities, the other with the College of Surgeons; we understand the former conference is likely to lead to an arrangement of the contested points.

WE insert the following report partly because we believe an injustice has been committed, although, no doubt, unintentionally, towards Messrs. HILL, EVANS, and Co., but chiefly on account of its intrinsic value and interest to the profession. From our own knowledge of the water from which the vinegar in question is made, we never had a doubt that the Analytical Sanitary Commissioners of the *Lancet*, had confounded in their report, free, with combined, sulphuric acid, but it has never yet been explained why, in the report of August 28th, the vinegars of three other firms are said to contain combined sulphuric acid, whilst the three samples said to be the make of Messrs. HILL, EVANS, and Co., are reported to contain *sulphuric acid not in a state of combination* to the extent of 2.80, 2.57, and 2.13 per 1000.

We have so high an opinion, generally, of the reports of that Commission, that we are unwilling to have our faith in the whole shaken by the

result of any careful examination of a part. But we cannot help fancying, either that the gentlemen conducting the investigation for the *Lancet*, attempted to discriminate combined from free sulphuric acid without the power of doing so, or that they stated as a fact detected by themselves by chemical analysis, that which they had been led to believe, from evidence external to their proper investigation, which of course would be an unjustifiable proceeding.

We do not come to this conclusion from any statements made in the report of the distinguished chemists selected by Messrs. HILL, EVANS, and Co., but from that published in the *Lancet*, for September 18th, in which the Commissioners state, "that with the exception of a very minute quantity, the acid (in the vinegar of Messrs. HILL, EVANS, and Co.,) exists in a state of combination." Now, if all the vinegars noticed, had been said to have been either free from, or adulterated by, sulphuric acid, the error might easily have been explained; but when we find that so small a proportion as '40 per 1000 of combined acid could be detected, *a fortiori*, 2·80 per 1000 might have been ascertained to have existed. This is a question, upon an answer to which the value of these sanitary reports must rest. Hitherto, we confess no satisfactory answer has been attempted, and it remains to be seen whether the confidence which has been reposed by the public is founded upon a satisfactory foundation. We do not assume that one error only, arising from inadvertency, should falsify a whole set of experiments, but we are of opinion that the assumption of more accuracy than chemical analysis will or can afford, is a mistake of the gravest kind. Messrs. HILL, EVANS, and Co., have been put to great trouble and expense, but we have no doubt their sale will be rather advanced than retarded by the publicity given to their process. We do not, therefore, on their account, call for an explanation, but we trust that for the sake of the public, who will either give or withhold their confidence as they find it deserved, the Analytical Sanitary Commissioners of the *Lancet* will be able to explain away the dilemma, in which they are now placed.

"The processes which are usually followed in the manufacture of the acid vinegar, that is, acetic acid, although greatly varied in their details, appear to involve only two important chemical principles. When billets of wood, enclosed in an iron cylinder, are distilled by the heat of a fire, like coal in gas-making, there passes over, in addition to tar, creasote, and such products, much watery fluid, sour from containing acetic acid, but

highly contaminated with the empyreumatic products referred to. This vinegar from wood, called pyroligneous acid, is largely consumed by calico-printers, dyers, and the manufacturers of white lead, who are enabled to make use of it from its comparative cheapness. It is less adapted for the table, from the extreme difficulty of purifying this acid in a perfect manner, and divesting it completely of every trace of its unpleasant accompaniments: while even in its fully purified condition it affords a vinegar destitute of the aroma and flavour which the liquid from other vegetable sources possesses. The absolutely pure wood vinegar bears, to such other vinegars, the relation of diluted alcohol to the wine of the grape and other fermented liquids, each of which possesses a flavour and bouquet of its own, in addition to its spirit.

"The alcohol in wine, beer, and all other fermented liquors, is readily convertible into acetic acid, by a chemical change which is uniformly of the same nature. The acetification of alcohol is, indeed, a process of the greatest simplicity, consisting as it does of nothing more than the absorption of oxygen from the atmosphere. By the addition of this element to the alcohol, that liquid is transformed into acetic acid and water.

"This oxidation of the alcohol is carried out in the most direct and scientific manner, in what is known as the German process, but which appears to have been imagined by Mr. Ham, of Bristol, quite independently, and patented in England about thirty years ago. It is this process which we have had an opportunity of observing in active operation in the vinegar works of Messrs. Hill, Evans, and Co., of Worcester, who were among the first to adopt and carry out Mr. Ham's ingenious ideas. Malt vinegar being the kind here manufactured, the antecedent operations of mashing the grain in water at a temperature of about 154°, and fermenting the sweet infusion thus obtained in large vats, by the aid of yeast, so as to convert the saccharine matter into alcohol, are necessarily the same as those of ordinary brewing, as seen practised in distilleries. The spirituous liquid thus furnished is suitable, without further preparation, for the oxidizing, which appears as a species of aëration, the spirituous liquid being showered upon the surface of a mass of faggots of birch twigs occupying the upper part of a large vat, and, after trickling to the bottom, being returned again and again to the top by the constant action of a pump. The oxygen of the air is continually absorbed by the circulating fluid; and the air, which is admitted by a small aperture in the vat below the level of the faggots, passes away by the openings in the cover of the vat, more or less exhausted of its active element. The process comes to a termination when all the alcohol is oxidized, and this is learned from the progressive rise in the proportion of acid in the liquid being found to cease. The product, when drawn off, is already finished vinegar, but is always kept in store for some time to clarify, or, as it is said, to mature it, before being sent into the market.

"This mode of oxidizing the alcohol, which is rapid and effective, appears to have the incidental advantage of changing and rendering insoluble certain glutinous and albuminous matters in the fermented wort, which are apt, if not got rid of at this stage of the process, to occasion after-muddiness in the vinegar, and to prevent its keeping. It was generally considered necessary in the vinegar trade, at a former period, to add a small portion of sulphuric acid to vinegar in order to counteract this tendency of the liquid to decomposition, and to preserve it from turbidity. This addition of sulphuric acid was permitted to the extent of one gallon of sulphuric acid to one thousand gallons of vinegar, by an excise regulation, and had, therefore, a legal sanction. But sulphuric acid is now known to be unnecessary in properly-prepared vinegars, although still added by some manufacturers, for the purpose of

increasing the strength of their vinegar, or, in some instances merely from habit and the indisposition to disturb the routine of an old-established practice. The presence of sulphuric acid in vinegar should be looked upon as the mark of inferior quality, for it is only where the mode of manufacture is defective that the addition appears to be at all necessary.

"It is the alleged addition of sulphuric acid to the vinegars of Messrs. Hill, Evans, and Co., of Worcester, that has led to the present inquiry, in the performance of which every assistance and facility was afforded to us by these manufacturers in obtaining the information necessary to form a correct judgment. The examination of the journals in which the daily operations of the manufactory are recorded for upwards of twenty years, afforded no trace of such a practice having ever been followed there; and an inspection of the works proved equally satisfactory. Samples were drawn from several vats fixed upon by ourselves, in the extensive stores of the establishment, which represented a stock of several hundred thousand gallons. The fermented wort before acetification, which was at the time in stock, the water employed upon the works in mashing the grain, were also taken for examination. The careful analysis of these products established the following conclusions:—

"That the water used, which is drawn from a well on the premises, is hard and alkaline, and contains a proportion of sulphuric acid in the form of neutral sulphates, principally sulphate of lime, amounting to 1·37 grains in 1000 grains of the water.

"That seven samples of vinegar contained respectively 1·31 grains, 1·33, 1·29, 1·23, 1·26, 1·25, and 1·25 grains of sulphuric acid in 1000 grains. This, it is to be observed, is no more sulphuric acid, or more properly sulphate found in the vinegar, than is contained in the water. Indeed, the proportion of sulphate proves to be somewhat less in the vinegar than in the water used in its preparation, no doubt from the known property of sulphate of lime to precipitate as an insoluble compound with the nitrogenous principles of the grain. This comparison of the water and vinegar have the slightest effect in injuring its quality; and this sulphuric acid, being neutralized, can in no way strengthen the proper acidity of the vinegar due to its acetic acid.

"It is to be remembered, also, that the use of hard water has its advocates among brewers, and that the keeping quality of vinegar made with such water may very possibly be improved, from the more complete removal of nitrogenous matter from the liquid, which, as has been already stated, sulphate of lime contributes to effect.

"The vinegars of Messrs. Hill, Evans, and Co., therefore, demonstrate themselves to be pure malt vinegars, wholly unadulterated with sulphuric acid; while, on the other hand, their strength is not artificially enhanced by the addition of pyroligneous acid, sometimes practised, and which would betray itself by an odour of creosote, when the liquor is heated, of which these vinegars were entirely free."

Medical Intelligence.

(From our own Correspondent.)

LONDON, Nov. 8, 1852.

Mr. Hunt, formerly of Herne Bay, the author of an useful work "On Diseases of the Skin," in which he clearly shows the very great reliance he places on the careful and sustained administration of arsenic in small doses for even a very long period of time, read at a subsequent meeting of the Medical Society of London;* a paper "On the Constitutional Treatment of Tinea, &c." These diseased conditions of the hairy scalp the author was inclined to attribute almost entirely to a constitutional cause, believing that derangement of the system and poverty of the blood, or deficiency of constitutional vigour, were the principal agents in inducing their occurrence. The affection, in all its forms, was believed by the author to be communicable by one and the same contagion, and to be either the consequence or the cause of a vegetable parasite, which, taking root in the hair bulbs, became a source of disease. Consequently, Mr. Hunt placed but little reliance on the efficacy of local remedies, but directed the treatment he adopted to the improvement of the general health, and the destruction of the parasite. Arsenic is with him almost a *sine quâ non* in the management of skin diseases; it is not likely, therefore, he would pass it by in these cases. Accordingly, he mentioned several cases in which he had employed it successfully, using weekly tepid water only, for the sake of cleanliness. He averred that it exerts a specific action on the hair-bulbs, and stated that in some cases of pure alopecia, which he looked upon as caused by the parasitic fungus, it had effected a cure. He concluded by observing that if the same principles of treatment should prove to be applicable for contagious forms of scalp disease, which he had found so practically useful in other chronic cutaneous affections, the difficulties of diagnosis would be reduced to a very simple and easy problem, as far as practice was concerned. For whatever may be the character of the disease, provided it were neither syphilis nor scabies, the only thing necessary was to rectify the general health, and, if that measure failed to restore the healthy condition of the skin, to administer some powerful alterative tonic in suitable doses for a proper time. For this purpose the author preferred arsenic, as being a remedy more manageable and more certain, and more permanent in its effects than any other.

The reading of this paper led to a rather warm attack on the author's ideas of pathology. It was condemned as unphilosophical, and far from being in accordance with the present state of knowledge. Diseases totally dissimilar in origin, nature, and character, and consequently in their treatment, had been confounded together, while local remedies, so essential for the cure of some of these, were almost totally neglected. The use of arsenic was not considered to be advisable in all these diseases, although it might be serviceable in some.

* "ERRATUM.—In the last report, in the title of Dr. Bennett's paper, for "Parulent Pleuro-pneumonia," read "Prevalent Pleuro-Pneumonia."

It is also uncertain in its operation, and injurious in many cases. No clear explanation had been given of the means of diagnosis between the different scalp diseases, nor between those which were contagious and those which were not. On the other hand, some of the speakers were very unwilling to regard the vegetable parasite in any way as the cause, but rather as the result of the inveterate scalp affection, the result of the decomposition of the tissues, leading to the origination of the low forms of life. Some of the speakers, however, defended the constitutional origin of all cutaneous maladies, and the consequent necessity for remedies capable of strengthening the system at large, and restoring it to health. Mr. Hunt's reply was very brief, the chief remark being to the effect that one of his principal objections to local remedies arose from their application obscuring the appearances presented, and thus preventing his observing the effects produced by the internal medication.

Prior to the reading of Mr. Hunt's paper, Dr. Ryan exhibited a portion of an umbilical cord, ruptured during delivery in the upright posture. This bore on a medico-legal question, having reference to the destruction of the life of the fœtus. Dr. Ryan referred to one or two cases in point. Mr. Richardson showed a specimen of internal strangulation of the ileum in a young pig. A brief discussion took place, in the course of which remarks were made on the inaptitude of the lower order of animals to bear up against the inroads of acute inflammation. It was stated that when the horse was attacked by acute pneumonia, veterinary surgeons generally considered the case desperate. In contravention to this, Dr. Ogier Ward alluded to the operation performed on cows, when in the state called "hoven," from eating large quantities of wet clover. The abdomen was freely pierced with a knife, and the distending gas evacuated. Notwithstanding this severe penetrating wound of the abdomen, the animal generally recovered.

While the embers of cholera are still smouldering in Posen and Berlin, and cases are even said to have been seen in Vienna, the reports from the West Indies, and from the more southern districts of the United States, are anything but gratifying. Yellow fever is exceedingly prevalent in Charleston, U.S., and at the Savannah, inasmuch that the Sardinian Board of Health, following the steps of our own wise Government, have decided on adopting quarantine measures against vessels coming from either of those parts. As that horrible disease, "Yellow Jack," is also decimating our troops in Barbados, a similar decree will doubtless be launched by the Sardinians against it. The disease first showed itself in the iron barracks (St. Ann's) occupied by the 69th Regt., and in less than a week it carried off more than twelve privates and two officers; the troops in consequence were withdrawn from the barracks, and encamped on the grounds of the Naval Hospital, at Hastings—a more elevated and healthy situation. This was soon found to be beneficial, and consequently a similar plan was followed at all the other barracks, the whole of the troops in garrison being encamped—a detachment of the 69th at Gun-hill, the Royal Artillery and the 34th on Brittan's-hill; the 69th have been since

withdrawn from the neighbourhood of the Naval Hospital, and they also are encamped at the former place, which is a very elevated and healthy situation. The fever has since assumed a much less malignant character; the cases in the hospital are less in number, several are convalescent, and it is hoped that the disease will soon be entirely eradicated. There are no reports of the fever from the country districts, but it broke out at Bridgetown almost as soon as at St. Ann's. It first appeared among the police, and in a few days it showed itself almost simultaneously in different parts of the city and suburbs, but its victims, considering the large population of the place, have been comparatively few. The latest accounts state that the fever has appeared in St. Phillips parish, and in the Blackrock district. While this epidemic is carrying off our soldiery in this beautiful island, our Government are employed in sending out more pabulum for the fever, in the shape of young unacclimatised soldiery and officers, intended to relieve the island garrison, but apparently destined for the grim clutch and dark embrace of fever and death. The *Megara* bears away this devoted band. Are human lives of no more worth? The mortality in Antigua during the last two months, in the absence of any epidemic, has been almost unparalleled. In British Guiana, the weather has been very dry, with intense heat, accompanied by an epidemic influenza and colds, coughs, and fever, prevailing extensively in the colony. There is a good deal of sickness in the Lucca, and two cases of fever terminating fatally, are recorded. The yellow fever is said to have abated considerably in Martinique.

APPOINTMENTS.

ROYAL SOUTH GLOUCESTER LIGHT INFANTRY REGIMENT OF MILITIA.—Commission signed by the Lord-Lieutenant of the county of Gloucester, of the city and county of the city of Gloucester, and of the city and county of the city of Bristol, Assistant-Surgeon William Philpot B. Brookes, M.D., to be Surgeon *vice* Tate, resigned.

The Honourable Board of Ordnance have appointed Mr. George Moseley, of Sandgate, Acting Ordnance Surgeon in charge of the Detachment of Royal Artillery, Shorncliff Barracks. The Detachment consists of a nine pound field battery.

Mr. William Adams has been elected to the St. Pancras Dispensary.

MEDICAL BENEVOLENT FUND.

The late Mr. J. Terrett, of Tewkesbury, Gloucestershire, has left, amongst other munificent bequests, one of £500 to the above most deserving fund.

UNIVERSITY OF LONDON.

Sixty-one gentlemen presented themselves on the 27th ultimo for examination for the degree of Bachelor of Arts, annually awarded by the Senate of this University. The candidates were examined in mathematics, classics,

moral philosophy, animal physiology, French, and German; the examiners being the Rev. Dr. Jerrard, and T. B. Burcham, Esq., M.A., Barrister-at-Law, late fellow of Trinity College, Cambridge. The examination terminated on Thursday, when those candidates who desire it may enter upon examination for orders, which commenced on Tuesday, Nov. 2, and will conclude on Friday, Nov. 19. There will also be an examination in the Hebrew text of the Old Testament, the Greek Text of the New Testament, and in Scripture history, commencing on Nov. 15. The examination for the degree of Bachelor of Medicine was appointed to commence on Monday, Nov. 1, and that for Doctor of Medicine, on Monday, Nov. 22.

GENERAL HOSPITAL BIRMINGHAM.

Mr. Oliver Pemberton has been elected one of the Surgeons of this Institution, in the place of Mr. Wood, resigned.

CHARITABLE BEQUESTS.

The late Mr. Thomas Croft, of Gravesend, has left £400, and the late Mr. Hunt, of Boxley, £10, to the Kent County Ophthalmic Hospital.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 29th ultimo:—John Armstrong, Manchester; St. John Edwards, Bangor, North Wales; George Davenport Freeman, Bath; William Giles, Sydney; Thomas Hillier, Stroud, Gloucestershire; William Body Mushet, Haverstock Hill, Middlesex; George Russell, Clifton, Bristol; Samuel Thorpe, Manchester; Alfred Tronsdale, Gainsborough, Lincolnshire; Heaten Lloyd Williams, Denbigh, North Wales.

INCOME AND EXPENDITURE.—From the annual report of the receipts and expenditure of the College in the year, from Midsummer-day 1851 to Midsummer-day 1852, it appears that the gross amount of receipts were £25,304. 13s. 6d., derived from the following sources of income:—The Court of Examiners, £8921. 12s.; fellowship, £220. 10s.; admission to Council, £42; sale of lists of members, catalogues, &c., £77. 8s. If to these sums are added the dividends on investments in Government securities, £1,021. 11s. 10d., the interest on exchequer bill, £22. 1s. 8d., and the late Parliamentary grant in aid of erection of additional museums, of £14,999. 10s., it will make a total of £25,304. 13s. 6d., as the total amount of receipts from all sources. The disbursements during the year amounted to £13,267. 3s. 6d.

THE FELLOWSHIP.—The Council of the Royal College of Surgeons have just announced that the next examination in classics, mathematics, and French, will take place at the College, the first week in November, and the professional examinations for the fellowship, the first week in December. We find, from the College list just published, there are at present 172 gentlemen who have undergone the examinations for the dis-

tinction, and 528 honorary and other fellows, making a total of 700. We are glad to perceive that the Council have placed a distinguishing mark to those fellows who have undergone the rigid examinations of the Courts of Examiners. This is an act of justice to which the gentlemen have a claim, and which has been considerably bestowed without any application to the College authorities.—*Lancet*.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Members on the 28th ultimo:—James Askwith Ellis, Bristol; Thos. Beard Farncombe Bishopstone, Sussex; George Bell Poppelwell, North Shields; Henry Tucker, Lyme Regis, Dorset.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

The Central Council of the Association beg to call the attention of those members whose subscriptions are in arrear to the following resolutions passed at the Anniversary Meeting, held at Hull, on the 7th and 8th of August, 1850:—

“But if any Member's subscription remain unpaid twelve months after it shall become due, the *Medical and Surgical Journal*, and other publications of the Society, shall be withheld from such Member till his arrears be paid; and when any Member has been in arrears of subscription for the space of *three years*, application shall be made for the same by the General Secretary, and if the arrears be not paid in *three months*, the name of that Member shall be omitted from the list of Subscribers; but this omission shall not be deemed, either in honour or equity, as releasing any Gentleman from the subscriptions owing during his Membership.”

Those gentlemen who have not yet paid their subscriptions for the CURRENT YEAR, or who are in ARREARS, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association at Worcester.

All post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

J. P. SHEPPARD.

Worcester, October 23, 1852.

Secretary.

ERRATA.

In Mr. Mitchell's letter “On the Acid Treatment of Diarrhoea,” by some unaccountable mistake a wrong signature was attached thereto. Instead of John James Mitchell, L.S.A., it should have been “James Johnston Mitchell, M.R.C.S., and L.S.A., Surgeon to the Western Dispensary of Bath.

TO CORRESPONDENTS.

Communications have been received from Dr. Tilt, Dr. Shapter, Epidemiological Society, Dr. Nelson, Mr. Reid, Mr. Coates, Mr. Collins, and Dr. Oke.

CLINICAL LECTURES
ON THE
PRACTICE OF PHYSIC,

DELIVERED IN THE
THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., EDIN.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c

LECTURE XVII.

ON THE MORBID CONDITIONS OF THE GENERATIVE
ORGANS.

GENTLEMEN,—The domain upon which I am now about to enter is one which has given rise to much disputation in regard to the strict boundaries of physic and surgery, especially amongst those members of the respective faculties who delight in splitting straws, and drawing hair-breadth distinctions; and as such disputations have frequently led, not only to mental contentions, but to ill blood, I think it right to state to you upon what principle we should decide all such questions, and thus furnish you with a touchstone that will test any case in a moment, no matter what part of the body may be involved, and this I shall do by the advancement of two fundamental propositions, viz. :—

Firstly,—That every case is medical which can be most effectually treated by prescription alone, even though requiring some slight aid from manual or mechanical appliances; and

Secondly,—That every case is surgical which can be most effectually treated by the said manual or mechanical appliances, even though requiring to be aided by prescription.

You must be aware, that in ancient times, even this distinction was not drawn, but that every appliance to the cure of disease was considered medical, no matter of what description—it might be a mineral, herb, bath, dietary, or the knife. No doubt there might be many men of a fine genius, similar to designers in painting, architecture and other arts, who might be able to point out with the most consummate skill, what ought to be done in any given case, and yet not possess the manipulative adroitness for carrying their views into practical effect. Such men might chose other persons, gifted with the necessary neatness of hand, to execute their intentions, and thus would arise the first division of labour. Afterwards, in the middle ages, it was deemed derogatory that any one of so high a calling as a physician should pollute his fingers with blood, and other humours, or do anything of a mechanical kind whatever; and therefore it became an universal custom for medical men to call upon an inferior order of persons—barbers and the like—to perform such things under their directions. In due time this state of things became altered, and certain medical men of good education, devoting themselves to the purposes of surgery more exclusively, that faculty began to rise to its present position, as a sister science with physic.

The vocations of these two sisters, therefore, as I have said, ought not so much to be regulated by the locality of the parts diseased, as by the nature of the duties which have to be performed. Nevertheless, custom must rule in all things more or less, and there are certain parts of the body that are commonly treated by the surgeon, even though the treatment be of a purely medical kind. Such parts I view as common ground, liable to be occupied by the physician from the nature of the appliances, and by the surgeon from common custom. Thus the eye, the ear, and the external organs of generation, are wont to be given over to the surgeon, even though the treatment of their maladies should be entirely constitutional; but yet there is no departure from office in the physician treating these parts, if the patient should desire it, and if they need no operative interference. When a gonorrhœa, chancre, and bubo, can be cured by dietary, internal medicines, and lotions, they are quite as much in the province of the physician as an inflammation in the eye, mouth, or rectum, and it is nothing but custom, and the disinclination of many men to deal with such loathsome ailments that send them into other hands, oftentimes extra-professional altogether.

It has been always found convenient in a high state of civilization, to divide professional functions to a certain extent; but while each branch may claim its due share of importance, we must never forget that ancient root or stock upon which they all depend. As the science of architecture is ever paramount in building, whatever may be the subsidiary crafts of masonry, carpentry, smithery, &c., so the science of physic is the one ancient and enduring root, upon which all the other branches of medical art must depend. We have got specific practitioners under the names of obstetricians, ophthalmists, aurists, dentists, syphilists and uterists, &c.; but these can only be useful in so far as they can bring some special skill and nicety of manipulation to bear upon their arts, without losing sight of the supremacy of general physic. This last observation bears particularly upon ophthalmists, whose delicate operations require a peculiar softness and minuteness of touch, which is often denied to the most skilful general surgeons. Without such special manipulative skill and regard to general medicine, however, such divisions would prove very detrimental to true science, and if too much multiplied would reduce the profession to a sort of fraternity of monomaniacs. You may smile at the expression—monomaniacs, but really, if you read the books of certain monographists, and observe how they endeavour to prove that “all the ills that flesh is heir to,” are traceable to their own favourite disease alone, whether it be the deranged stomach, the ulcerated uterus, the syphilitic virus, or the wonderful Hahnemanic itch, and thereby claim all cases for themselves you will perceive that it is not overstrained at all, but strictly just and applicable. The uterists among the female sex, and syphilists amongst men, women, and children, of every age and degree, are especially liable to this condemnation, and some of the latter have recently been writing *ad captandum* books upon this

subject, both in French and English, which our best reviewers have justly designated as a scandal to any honourable profession. In fact, this bastard order of pure or rather impure syphilists, and spermatorrhoeists, for they are not to be ranked as physicians or surgeons, would not only have their own rod, but would make it, like Aaron's, swallow up all other people's rods, and so create a monopoly of all human ailments for themselves. And this sense of self-importance which they are wont to entertain, is all the more ridiculous, when we consider that syphilis is clearly a physicians disease or disease of the blood, when manifesting itself constitutionally, and as clearly a case for the surgeon, when exhibiting itself by external ulcers, &c., and that the worst cases of this kind have only been thrown in an exclusive manner into such persons hands, because the more eminent professionals have not desired to overburden themselves with such filthy and loathsome practice. Such cases will present themselves in every man's career, and we are bound in duty to relieve human suffering in whatever shape it may come before us. It is also well that there are minds so constituted as to take especial interest in such matters, and so relieve the rest from certain sickening duties; but it would also be well if they could understand their true position, and not play "such fantastic tricks," as make men laugh or "angels weep." You will find that Dr. Graves, Mason Good, and in short, all other physicians, in their systematic writings, treat regularly of syphilis, and do not bate one inch the universal domain of physic, and it shall therefore be handled in these lectures as a matter of medical inquiry, though, as a blood disease, it will belong to another part of the course. While conceding to such persons a good deal of the merely practical ministrations, we cannot permit them to ride their hobby-horse of theory and doctrine, or else they may become as great nuisances to society as the old oculists were, when permitted to ride their hobby-horses by the more scientific surgeons of past times, a subject well commented upon by Mr. Middlemore, at the very commencement of his "Treatise on Diseases of the Eye," and in which he further justifies himself by quoting the philosophical views of Mr. Lawrence. Thus much I thought it necessary to say on the question, for, with such persons almost *everything* is viewed as a form of syphilis, and if the patient should positively deny it, the responsibility is forthwith thrown upon the shoulders of his father or mother, or Adam and Eve themselves, rather than give up the opinion.

Notwithstanding these observations, however, I am by no means disposed to appropriate such cases, but have always acted according to custom, though not conceding the principle. Hence I have never treated, except at the express desire of the patient, any affections of the external organs, beyond incipient chancres and buboes, and these only, when they could be managed by constitutional appliances alone. Therefore I shall not now remark upon any disease whatever of the penis, testicles, or vulva, but shall confine myself entirely to the disorders of the ovaries and uterus, admitting their full importance in every inquiry into constitutional

disturbance, and the necessity of carefully studying their diseased conditions, yet not yielding to the morbid rage of the day in tracing every ailment of the female to that source alone, and of subjecting all women, whether married or single, to questions incredibly disgusting, and to unnecessary examinations by hard instruments and other foreign appliances, calculated, by their irritation, to increase existing disease, if not to excite it where not existing before, of which most practical physicians could give too many instances, if the task were not invidious. Like other affections in other parts, they may be classified into nervous or functional disturbances—anæmic or hyperæmic conditions, and degenerations. Amongst the nervous disturbances, we may first consider paralysis.

PARALYSIS, either of the ovaries or uterus, can be but rarely witnessed except as an accompaniment of that universal malady which has been already treated of while discussing the affections of the brain and nervous system. The total paralysis of the ovaries it would be difficult to prove at all, though it sometimes occurs in the womb as an accident during labour, or immediately after it, when, by non-contraction it gives, rise to hæmorrhage and other dangerous consequences requiring instant and decided interference. Most commonly, however, this is but a temporary condition, which is subdued by the usual treatment of confining the uterus within the grasp of the hand, or compressing it within the circumference of a large cup or bowl, applied by force over the abdomen, or by exciting the internal surface by the points of the fingers, and the administration of ergot and other uterine stimulants. That such defect of nervous action is uncommon in the uterus might be readily guessed, considering how very frequently that organ is able to perform all its functions, while the rest of the body, or of the general cerebro-spinal nervous system, is in a state of abeyance or torpidity. Thus it will act quite freely in idiocy, in spinal paralysis, in the stupor of typhus, or apoplexy, or under the influence of chloroform, and even after death itself,—that is to say, somatic death, death of the cerebro-spinal axis, or, conscious being—the ganglionic or vermicular sensibilities, so to speak, being partially effective. Hence, in the dead-house, there has been such a thing as *post-mortem* expulsion of the fœtus, I will not say how long after apparent death, but certainly after the heart and lungs have ceased to act under ordinary stimulants, or after the woman has been considered dead and carried away. But though complete paralysis be a very uncommon occurrence in the womb, torpidity both of that viscus and of the ovaries is by no means unfrequent. Such a condition may arise from original constitutional defect, or from a morbid state of the blood, or from long-continued pressure of the fæces, or common tumours, or certain affections of the brain or spinal cord, communicating their deadning influence to the local ganglionic nerves, and thus blunting their sensibilities. Hence we may have a sexual indifference, with deficiency of the natural passions, and a purely functional amenorrhœa. The girl or woman may, under these circumstances, possess a timid mind, and a weakly

half-developed frame, yet nothing of the truly feminine softness and sweetness of character, and she will have a childish bashfulness instead of the sensitive female modesty, that is to say, if the condition be congenital or permanent.

If it be, on the other hand, only accidental and dependent on the removable causes above indicated, there will only be a temporary blunting of the ordinary feelings, and a partial deficiency of the usual routine processes, which feelings and processes may be restored to their native activity by a removal of such causes. That the start of the ovary into active glandular existence is the primary impetus of all that follows throughout the rest of the female generative system, is now pretty well established, by whatever other secret agency that event itself may be preceded. The chain of sympathy thus established, continues during life, and the order of events—whether morbid or healthy, is always maintained according to the original development of functional activity. Thus the conditions of the ovary are more likely to affect the uterus and external appendages, than those appendages are to control the ovary; though, certainly, the latter is affected in a minor degree by the former, because there is a reflex principle at work, as well as one of central origination. The nervous influences play in a circle, and sweep around that circle both backwards and forwards, but yet the circumference does contain a special point of activity, and that point of activity in this instance, is the governing force of the ovary. The labours of Dr. Tyler Smith in this direction, as bearing upon the practical applications of science to obstetric art, are well worth your study. And Dr. Tilt has also endeavoured to enforce a full consideration for the ovary in all uterine affections. The results of the cases given by him are quite pertinent to the question, though we must guard ourselves from tilting too much against one offending member only, and thus narrowing our vision to an unsafe compass. Viewing the growth of the ovary, then, as the cause of all the other subsequent growths that characterise puberty, and accepting the decided manifestation of sexual preference, as the chief proof of such ovarian growth, you will remember that a case was recently presented to us, which seemed upon the first inquiries to contradict such a theory. The girl, Selina H——n, was about twelve years of age, and was brought by her mother to the hospital in order to be cured of a shaking of her head from side to side. This did not seem a matter of any great consequence, except from its giving her a strange and awkward manner, and exciting amongst observers a painful and impatient desire to put a stop to it. There were other peculiarities, however, which made me retain her as an in-patient and as a physiological curiosity for your observation. She was very short and squat, and her head was preternaturally large, both in breadth, depth, and length, but especially the latter. Her face was childish, and its childish expression was increased by the short crop of hair which she wore; her shoulders were broad and rounded, her bust very full, and the mamma quite as large as those of a stout woman of 40, who had suckled children. The hips and thighs were

proportionally developed; but the legs were like those of a child of about eight or ten years of age. Her mother stated that these growths had commenced when she was about eight years of age, but that she had never menstruated, nor exhibited any sexual propensities. She appeared therefore to be doubly a curiosity; but it soon appeared, from the reports of the nurse and of the other patients, that however she might have deceived her mother, she was not long before she enlightened them, for she seemed to take a peculiar interest in talking upon such subjects, and related to them sundry adventures that she had had with a certain cripple, and some other favourites. A seton behind the neck stopped the shaking of the head, which appeared to have been merely a bad habit, and she soon left the hospital. Everything else seemed to be active here, excepting the process of menstruation, which therefore would seem to be the latest link of the chain. Indeed we generally find the mammæ, &c., well developed, considerably before any appearance of this discharge. Nay, pregnancy itself has occurred without that phenomenon having, as yet, manifested itself.

As to the treatment of this torpitude of the ovaries or uterus, it must depend upon the causes which may give rise to it. If it be simply due to a slowness of development, it may well be left to itself. One may be frequently consulted in regard to girls of 17, 18, or 20, in whom menstruation has never occurred; but in all such cases, unless anything else was detectable, I have invariably prescribed nothing whatever beyond a natural mode of living, and cheerful mixed society. Where anæmia appears to be the cause, carbonate of iron, or some other preparation of steel, is absolutely essential; and it is also advisable to combine such preparation with assafœtida or galbanum, in conjunction with aloes, as special stimulants of the pelvic region. Some physicians have indicated that these latter agents should not be employed in permanence, but should rather be exhibited as adjuvants to the steel at the time when the monthly periods come about. But though this rule may be applicable to women who have already menstruated, and in whom the function has only been arrested, we cannot apply it to those who have never menstruated at all, inasmuch as we do not know their natural time, since the old story of the influence of the full moon has been exploded. Iron and assafœtida, and aloes, therefore, are our chief anchors under such circumstances—the former as a *sine qua non*, the latter as adjuvants. But, should the torpitude proceed from any cerebral or spinal affection propagated to these parts, then we must look to those centres as the primary seat of the malady, and treat them according to the rules laid down while considering nervous diseases. The same advice would apply to any tumours, or other fluids or solids pressing upon the organs, and impeding either their blood-circulation, or their nervous play, though the management would be difficult according to the solidity or the seat of such impediments. Not an uncommon cause of this kind, and one very easily removed, is constipation. Girls at this age are apt to suffer from this complaint on account of their seclusion,

and dulness, and sedentary habits at a school. Nor are they likely to speak of it like older people, but suffer it to go on, as if it were a matter quite natural, and never complain until the portal circulation becomes so impeded as to lead to the secondary and tertiary symptoms of pain, sometimes in the one side, and sometimes in the other, with sickness, indigestion, giddiness, and headache. In such case the abdomen will be found hard, dull under percussion, and perhaps knotty and lumpy along the course of the colon. It is surprising what large amounts of scybalous feces may sometimes be discharged from the bowels during a continued course of moderate purgation for this state of things, and it is the only process by which health may be restored and maintained. The kind of purgatives employed must altogether depend upon the general state of the system. If the patient be plump, strong, and of good colour, the blue pill or calomel at night, with a saline in the morning, may be desirable; but if she be thin, puny, and pale, the warmer purgatives of aloes, colocynth, or scammony should be employed, in conjunction with some stomachic tonic and aromatics. After a brief treatment of this kind, variety of diet, with cheerful companionship, and open-air exercise, will be the best means of avoiding the necessity of recurring to it.

Before leaving this subject, there is one very important caution that I would offer to you in regard to the employment of strong purgatives and emenagogues, under representation of obstinate costiveness and amenorrhœa, received from certain hospital and dispensary patients, and perhaps, also, parochial patients, though these latter are not so apt to practise it, on account of being generally less nice as to their moral reputation. Such representation of costiveness may be made falsely, under a conviction or suspicion that they are pregnant, and in hopes of getting, (to use the words they have used,) "something that may carry it off." Carbonate of iron, and mild aperients, can never do any harm, but I can see no cause for resorting to very powerful medicines in such cases, nor any necessity for prying too curiously into the question of pregnancy. Even when the question is directly put, it is better to evade it, except in the case of a married woman, to whom the fact may be agreeable. Some may feel inclined to exhibit their penetration upon this point, by spontaneously asserting the fact, even when the young women have themselves positively denied it. I conceive this to be not only unnecessary, but dangerous, for they will frequently never visit such practitioner again, but resort to some old witch or other, and forthwith obtain the means of ridding themselves of their burden. Such an uncalled for declaration of the fact of pregnancy cannot, by any imagined possibility, do any good, while it may, undoubtedly, prove suggestive of certain proceedings which shall cut off the existence of one human being, and perhaps encourage the other in a long course of systematic vice and crime. Let such a person but arrive at the fourth or fifth month of her time, and then matters will be so apparent to the world at large, as to leave less fear of any tragical issue. But let us avoid giving the diagnosis at too early a stage in

unmarried women, who may be unprincipled, or very fearful of public shame, for the result in child murder is no fancied evil but one that is constantly arresting our attention, and increasing in this country year by year.

SPASM, or painful involuntary action, does occur in the ovaries, and in the fimbriated extremity of the fallopian tubes, if we are to judge by the phenomena that sometimes present themselves in that quarter, and the dull uneasiness that follows afterwards. In the uterus spasm is a very frequent occurrence, with some women during their whole lives, and, in most women, under certain circumstances, giving rise to any degree of pain, from a slight dull occasional aching, to the most grinding and sickening agony. The spasm may arise from a condition of simple irritability, rendering the organ painfully sensitive to conditions of which it might not otherwise be at all conscious. Of course we are not at all surprised at its spastic action in parturition, or even at its strainings afterwards to expel the vitiated or putrid lochia. But it ought not, in the natural state, to suffer greatly during menstruation, and much less from that simple determination of blood which precedes the discharge; yet that is the period at which this morbid spasm chiefly presents itself to our notice as an object of treatment, or else during the earlier stages of pregnancy, when it is apt to lead to abortion. That it generally proceeds, either from a simple irritability, or from a certain amount of hyperæmia, inducing vitated secretions, and exciting reflex action, is, I think, very apparent, judging from the success of those measures which are directed to the subduction of these conditions. Narrowness of the uterine aperture or passage has been pointed to as the cause of this spasm, and of painful menstruation, but I am persuaded that it is a comparatively rare one. I know that such a condition does occasionally exist, and have treated for such a condition in this hospital, in the person of Mrs. ———, of the top ward; but we should not be justified in using, as some do, the speculum so indiscriminately in all such cases, and introducing dilators and other mechanical forces into the uterus, under some, *a priori*, hypothesis, that there must be physical obstruction in every instance. The cases of dysmenorrhœa and other forms of hystericalgia, which we have had, are too numerous and too uniform in their features to be spoken of individually on this occasion, besides which, they have been almost always observed amongst the out-patients, of whom no very precise records have been kept. Suffice it to say, they have all been characterised by pelvic pains, chiefly recurring during the catamenial periods, that these pains have been felt to extend to the sacrum, round the ilia, and down the thighs, and that they have not been accompanied by any permanent tenderness or soreness on pressure, either over the pubes or at the neck of the uterus, except in those instances where some degree of hyperemia was considered to be the cause.

With the exception of the one patient above alluded to, none of them required any mechanical interference with the os or cervix uteri. Only in a limited number were leeches required to the vulva, and the far greater

proportion of them recovered under sedatives and tonics; the latter being steel and quinine, and the former consisting of belladonna locally applied, with conium, morphia, or aconite internally—the latter, undoubtedly, the most efficacious. The constitutional condition of ANÆMIA is not an unfrequent cause of this hysterical spasm; but, as that is a blood affection, its consideration will be for the present deferred.

HYPERÆMIA is always one of the chief sources of derangement of function, both locally and generally, and is a very common occurrence indeed in the organs of which we are now speaking. It may be arterial or acute, giving rise to positive inflammation; or it may be venous and capillary, inducing a subacute action or passive congestion, the latter being, by far, the more common of the two states. The causes may be either a primary irritability of the parts, or the presence of local irritants or obstruction to the local circulation. The acuter form of the disease will be unmistakable as to its character, though the locality may not be so readily diagnosticated by the inexperienced observer. There will be severe pain in the parts, whether they be the ovaries or the uterus. The pain will be increased under pressure, and the constitutional excitement will be considerable, and more apt to be accompanied with nervousness and hysteria, than when the bowels or bladder are affected. If the disease be in the ovary, the pain will be referred to that quarter; and some degree of heat, and perhaps swelling, may be discovered, if not through the parietes of the abdomen, yet through the vagina or rectum. The pain will be deeper seated than if the gut were diseased, and will also extend more deeply into the back. If the uterus be affected, the pain will be over the pubis, and at the lowest part of the sacrum; and it will not only be increased by pressure in front, but by the gentlest motion given to the cervix by the finger, which will also feel the vagina very hot and dry. The stools, from the swelling of the organ, may be flattened, and will be passed with pain; and you will readily discriminate the disease from inflammation of the bladder, by the state of the retractive discharges, and by the tenderness being less superficial. The symptoms of the chronic or passive forms of this malady, will be altogether the same as those of the acute, excepting that they will be less in degree, more dull and obscure, less apparent, or perhaps not at all apparent, except upon a careful examination. Thus the pains may be so distressing round the sacrum, the ilia, and down the thighs, that the woman herself at once reports them to you, as well as her profuse, or lessened, or suppressed catamenia, or her red or white discharges per vaginam. Here there will be little difficulty in the recognition of a chronic ovaritis or metritis, of which the leucorrhœal discharge is a constant accompaniment; but, on the other hand, the symptoms may be such as to give but a faint indication of what is going on, in fact, they may be more felt in the stomach, and in the general constitution, than in the part primarily affected, and hence the necessity of diligently inquiring into the condition of the ovaries and uterus, whenever you find a woman

complaining of a dyspepsia more obstinate than usual, or of a languor and debility, and general uneasiness not otherwise to be accounted for. In such a case you might go on treating the digestives, and the constitution at large, in vain, for any length of time, unless you addressed yourself to relieve the turgidity of those organs. Accordingly, upon due examination, you may find that there is dull pain, under deep and soft pressure, over the groins or pubes. You may also find some degree of leucorrhœal discharge, and a greater or lesser amount of tenderness or uneasiness upon moving the cervix uteri with the point of the finger. It must be thoroughly understood, however, that all these operations should be particularly delicate and gentle; for any rough fellow might otherwise manufacture all the features of a disease by dint of sufficient poking and jerking. The existence of leucorrhœa, as one of the earliest appreciable symptoms of the disease, should always be inquired into in female cases; and, if such symptom should not readily yield to the common astringent applications, then a more precise examination should be made, for it is then pretty sure to be dependent on a turgid state of the uterus or ovary, and not upon a mere vaginal catarrh. The disease most commonly exists at the os and cervix uteri, which, from its turgid condition, does undoubtedly produce a narrowing of the orifice, though not of a truly organic character, and hence the occasional obstruction to the catamenial flow, which would certainly never be removed by attempted physical dilatation, but rather increased. In the early stage there will be a full, soft, velvety feel around the os, and this may further lead, under impressions from foreign bodies, to desquamation, abrasion, or so-called ulceration of the epithelium. But the action may extend more deeply, and induce exudations of a more permanent kind, in the cellular tissues beneath, which, by their consolidation, may form an indurated mass, which, if neglected, may end in scirrhus, and ultimately, cancer. It is this consideration which constitutes the great necessity for a proper examination at the early stage of the complaint, in order that such terrible contingencies may be warded off. In some of the more serious manifestations of the disease, as exhibited in old indurations, cauliflower excrescences, and corroding ulcers, difficulties will sometimes arise in discriminating these from scirrhus or open cancer; but I shall enter into these questions in my next lecture, when I shall also speak of polypus, prolapsus, and ovarian dropsy. In the mean, time I shall merely indicate the treatment of ovarian and uterine hyperæmia.

First of all, it is desirable that leeches should be applied, and these should be proportioned to the strength of the patient, and the degree of the disease. We are not to be deterred from this course by the presence of any menorrhagia or uterine hæmorrhage, for that frequently depends upon an engorged state of the vessels, and ceases as soon as such engorgement is relieved, as will be illustrated to you in due time by sundry cases. The next step of the curative process will consist in the application of blisters either over the

sacrum, pubes, or groins, according to the seat of pain, and they must be of a size and frequency to meet the particular emergency; at the same time, if the action be severe, mercury may be required, either exhibited internally, or applied by poultice or friction over the morbid part. Along with these appliances, sedatives may require to be employed, such as morphia or aconite internally, or the belladonna plaster externally, following the blisters. If the nausea, or other dyspeptic symptoms be urgent, draughts of columba will be advisable, in conjunction with soda or magnesia, and hydrocyanic acid. When the symptoms of engorgement are subdued, local astringents may then be used, with good effect, but not before; and if decided ulceration exist, of an indolent character, such as cannot be subdued by the above means, nitrate of silver may be necessary, though I would wish to convey to you that, under the condition of much vascular turgescence, such applications as those of the speculum and nitrate of silver, are only likely to increase the mischief, and are not desirable till the vascular action and ulceration have assumed a sluggish and indolent form. If any very solid indurations exist, the potassa fusa may also be of great use, but I shall treat of that when we meet again. Let me only now conclude by observing, that all such inquiries and appliances are to be carried on with the greatest delicacy and regard to the patient's feelings, to whatever rank of life they may belong, but that they are not to be prefaced by foolish apologies, or by formally asking permission to do this or that. All examinations of the kind, when instituted by judicious men of a proper age, are entered upon as a mere matter-of-course duty, the same as in obstetric practice. The woman knowing her sufferings, and having confidence in her attendant, complies with what is requisite in silence; but any unnecessary apologetic requests will only cover her with a sense of shame, and expose you to ridicule, and, ten to one, end in a refusal. Thetact, required, however, in such matters, is perhaps natural, and not to be acquired, for good feelings will produce good manners—good beyond all the artifices of studied refinement.

ON THE DIAGNOSIS OF CHRONIC OVARIAN TUMOURS.

By E. J. TILT, M.D.,

Senior Physician to the Farringdon General Dispensary and Lying-in Charity, and to the Paddington Free Dispensary for Diseases of Women and Children.

"Hydrops ovariorum ut plurimum steriles annosaeque mulieres occupat difficilius cognoscitur et vix sine sectio cadavere."—Boerhaave (*Aph.* 1223.)

(a) *Cysts of the Liver have been mistaken for Ovarian Cysts.*

NUMEROUS cases of this description might be recorded. Mr. Harvey, (*Lancet*, 1849, p. 183,) has drawn attention to a case of cyst of the liver, which was considered ovarian. An amber-coloured fluid was

withdrawn, and extirpation was contemplated, when inflammation set in, and the patient died. On opening the body, the cyst contained pus. In this case there was no jaundice, as sometimes occurs, to help the diagnosis. We know of several similar cases. In one, of cirrhosis of the liver, with extensive ascitic effusion, the abdominal swelling was so far considered ovarian by one of the ovariologists, who prides himself the most on the accuracy of his diagnosis, that he wanted to extirpate the tumour. Thus an ovarian tumour does sometimes assume varieties of form, sufficient to deceive the most experienced. An instance of this came very lately to our knowledge, where several who were consulted, denied altogether the ovarian origin of the tumour, attributing it to the liver, though, after death, it was proved to depend upon the ovary.

How to avoid such errors.—It will not be difficult to do so before the tumour has attained to a great size. It will be found descending from above downwards; and the pain, if any, is referred to the hypochondria, and not to the ovarian region, but sometimes there is no, or but little pain, in the beginning of such cysts; and we are seldom applied to before the diagnosis is complicated by their increased size. Then the patient may help us by affirming whether she previously suffered pain in the hypochondriac region, whether the tumour began in the side, whether jaundice had been one of the incidents in the patient's history. A cyst in the liver may be inferred by the distinct perception of the *fremissement* indicating hydatid bodies which are much more frequent in the liver than in the ovary. In cases of insurmountable difficulty, when the patient has not had jaundice, and is too dull to help one to unravel the intricacies of her case, the decision must be deferred. It must, however, be borne in mind, that hydatid cysts, (if left to themselves,) are in general fatal long before the tumour has attained anything like the enormous size other encysted tumours are capable of. The displacement of the liver has been noticed in some rare instances, and might at first sight be considered a morbid tumour in both sexes, or an ovarian tumour in women, but it could not be displaced without its absence from the right hypochondrium being made visible by the depression of the abdominal walls.

(b) *Cysts of the Spleen may be mistaken for Ovarian Tumours.*

Case.—I have seen, says M. Tavignot, (*Journal des Connaissances Med. Chir.*) a fibrous tumour of the spleen, thirty-five centimetres in length, extending to the brim of the pelvis, and which was taken to be an ovarian cyst. The tumour was evidently fluctuating, still on being punctured not a drop of liquid escaped. On opening the body the cyst was found full of hydatids of all sizes.

Remarks.—We know so little about the functions of the spleen, (and such cysts are so very rare,) that whenever a similar instance occur, it will doubtless be similarly mistaken. One great advantage of the plan we have proposed for the cure of ovarian dropsy, (treating it by the application of potass. fus. c. calce,) is, that in.

case of an error of diagnosis, the treatment applies equally well to the cure of hydatid cysts of the liver and of the spleen. The case just related was most favourable for that plan of treatment. The hydatids might have been evacuated, the mother membrane peeled off, and a cure effected, as in numerous cases of hydatid cysts of the liver so treated, first by M. Recamier, and afterwards by many others, both at home and abroad. There are several well-authenticated instances of the enlarged spleen descending into the abdomen; and as its absence, unlike that of the liver, would not be immediately missed, there would be nothing to indicate the nature of the tumour, while if it occurred in a woman, as it most frequently does, this solid tumour, surrounded by intestines unconnected with the womb, might be thought ovarian, and with difficulty shown to be otherwise. Riolan saw four cases of the enlarged spleen, descending in the hypogastric region, and in two the spleen so adhered to the womb that it could not be removed from the dead body. Morgagni has published a similar instance observed by Maufredi; the spleen weighed three pounds, and was six inches square. In the case of Madame de Pozzi, the spleen for twenty-four years had occupied the hypogastric region, and the woman was safely delivered of three children. The disease has been taken for pregnancy, (Drelincourt.) Morgagni says he has only read of ten cases—six in women, two in men, and two not stated. They were in general painless.

(v) *Encysted Tumours of the Peritoneum may be mistaken for Ovarian Tumours.*

Notwithstanding the assertions of B. Bell, (in his "Surgical Lectures,") of Chopart and Desault, (*Traité des Maladies Chirurgicales*, Vol. 2, p. 348,) of Boyer, (*Traité des Maladies Chirurgicales*, Vol. 8, p. 346,) of Bricheteau, (Art. "Kyste du Die," en 60 Vol.) encysted tumours of the peritoneum are very uncommon, otherwise these authors would have been able to describe the complaint. In the absence of such description, we shall condense a case, which well illustrates this singular disease; it was published by M. Fano, (*Union Méd.*, Vol. 8, No. 106.)

Case.—Claude Blin, aged 48, entered the Hôpital du bon Secours, December 18, 1846. He stated that until the previous April he had enjoyed good health, but then he felt a small tumour in the left hypochondrium, when, as it increased in size, he entered for a short time in July, the Hôpital St. Louis. Here he vomited bile several times, the tumour increased until the December above named, when the circumference of the abdomen just above the umbilicus measured *eighty-six centimetres*, the abdomen being distended by a tumour, which formed a more considerable swelling on the left side. The tumour was irregularly round, and was dull on percussion on the left side, as high as eight centimetres above the crest of the ilium, and in the whole of the left iliac fossa. When grasped with both hands it gave an obscure sensation of fluctuation, and in some points, more particularly at the epigastrium, a *crackling*

sound. Dr. Moneret, in whose wards the patient was placed, determined to open the cyst by *potassa fusa*, and between the 25th of January and the 23rd of February, eight applications were made. The adhesions of the cyst to the abdominal walls being deemed sufficient, M. Denonvillhier plunged a trocar into the eschar, and withdrew about twelve pints of an albuminous liquid, like coffee-grounds. An oval tumour could then be felt, its longest diameter inclining from the left hypochondrium to the right inguinal region. The following days the pulse rose. A mixture of foetid pus and gas came out on pressing the cyst.

March 8th.—Barley water was injected, and repeated daily into the cyst, with good effect. The patient was able to get about, and could take half his portion of food.

April 23rd, and following days.—Injections were made with wine, or weak brandy and water, to effect inflammatory adhesion of the sac. This did not give pain or fever to the patient.

27th.—The female sound did not penetrate easily. Efforts were made to pass it, and when tepid water was injected, the patient felt excruciating pain, and the liquid did not return, as usual, by the sound. The patient died at midnight, after symptoms of acute peritonitis, which nothing could alleviate.

Post-mortem examination thirty-four hours after death.—The pelvis contained a considerable portion of a sero-sanguinolent liquid, in which false membranes floated; the intestinal circumvolutions had an amaranthine colour, and patches of purulent matter were deposited where the injection was greatest. To the left of the abdomen the *gastro-colic* epiploon was lined by a red flesh-like substance, which extended to the adhesions formed all round the fistulous opening, and on passing the sound through the fistula, it became evident that the cyst had been ruptured during the patient's lifetime; all round the orifice of the fistula were solid adhesions, of about the size of a shilling, formed by the peritoneum, so thick as to look fibrous. The cyst was large enough to contain a man's fist, and was formed in the smaller cavity of the peritoneum; it was limited above and in front by the stomach and the transverse colon, laterally by the spleen and the descending portion of the colon, below by the *great epiploon*, and posteriorly by the vertebral column. The cyst itself was not cancerous, but of a cellular structure, and of considerable thickness; it was lined by a dark membrane, contained fragments of the same colour, and exhaled a foetid-odour. The other organs presented nothing unusual.

Remarks.—The form of the abdomen would have excluded all thoughts of ascites. The manner in which this tumour, notwithstanding its growth, left unimpeded all the functions of the body, might perhaps have prevented its being considered to be connected with the liver or the kidney, but certainly if it had occurred in a woman, it would have been set down as ovarian. The uterine sound is our only means of distinguishing such a tumour from an ovarian, and that not by positive

information but by negative signs. "I have found, (says Dr. Simpson) however, advantage from the negative information given in other ways by the bougie, even when the tumour was abdominal in its seat. An example will best illustrate my meaning. In a case sent to Edinburgh a few months ago, for the purpose of having some opium given in regard to its nature, an immense abdominal swelling that was present, and which had been supposed by some medical gentlemen who had seen the patient to be ovarian, was shewn not to be so by sufficient evidence of the following nature. The uterus was displaced obliquely backwards, and the fundus of the bladder was displaced to the right iliac region by the abdominal enlargement, circumstances which were easily ascertained by introducing the uterine sound into the cavities of both these organs. Further, the uterus, although displaced, was quite moveable, and when its fundus was turned by the bougie towards the site of either ovary, the abdominal tumour lifted up as high as possible towards the epigastrium. No obstruction was met with, nor was this great change upwards in the direction of the tumour found to produce any dragging effects upon the uterus, as held by the bougie or its connections, effects which, unless under the improbable supposition of a pedicle several inches long would have inevitably occurred if the diseased mass had originated in, or was connected with, the ovaries or uterine appendages. So far the evidence was negative, but so far important. I may add, that other characters of a more positive nature,—the history, the particular form, and consistence of the tumour, its position in point of substance as ascertained by percussion, &c., seemed to show, seeing that it was not ovarian, to be in all probability one of those hydatigenous tumours that sometimes form in the tissue of the omentum, and whose physical symptoms during life in many respects correspond with those of ovarian dropsy."

(9) *Can a Lumbar Abscess be mistaken for an Ovarian Tumour?*

We know of no case of this mistake, but when on the one hand we reflect on the obscurity and size of some of these abscesses, and remember on the other, that every species of voluminous swelling occurring in woman, has been ascribed to ovarian disease, we should not be surprised at the mistake, the more so as the swelling in both diseases generally occupies the pelvic region; but when these large collections of pus are the result of caries of the vertebrae, or some other bone, there is a deep-seated pain not met with in ovarian dropsy—an inability to walk, a certain amount of vertebral deviation and of acute symptoms so well known, that such a mistake cannot easily be made.

(1) *Various Diseased States of the Intestines may be Mistaken for Ovarian Dropsy.*

It seems strange at first, that a canal formed of such thin tunics should ever be able to represent large ovarian tumours, but when we remember that the canal may be partially obstructed, and its tunics are susceptible of

surprising distension; when we reflect how beautifully their great length is suspended around the small area of the mesentery, so that each fold is perfectly free, so long as its peritoneal covering remains sound, but may become glued to the adjoining folds when the peritoneum is inflamed we are no longer surprised to find that the various morbid states of the intestines have often embarrassed the most eminent, and led the inexperienced into deplorable errors. And here we must recollect to the readers's recollection that the tumour may cap itself with the intestine, and on making a rectal examination, the walls of the rectum were felt so strongly pressed together, that the first impression is, that the tumour is intestinal, so much does it seem to rise from the intestinal surface.

(2) *Tympanitic Distensions of the Intestinal Canal have been mistaken for Ovarian Tumours.*

By referring to Dr. Atlee's table the reader will find that in six cases this strange mistake has subjected the patient to the operation of gastrotoomy, and the operator to the annoying reflection of having made an egregious blunder. Mr. S. Lee says:—"I have been lately consulted by two patients who supposed, and who had been told, that they were labouring under dropsy. At first one was thought to be pregnant, but latterly dropsical. She certainly presented a peculiar appearance. The abdomen was very much distended, almost to the size of the full period of gestation, and her gait was that of a pregnant woman. On examination however, the uterus was found to be healthy, the abdomen greatly tympanitic. This tympanitis has now entirely disappeared, and the patient is as small as ever she was." Dr. Corfe also mentions having seen repeated instances of meteorismus simulating pregnancy, disappear after marriage and childbearing. When the accumulation of air gives rise to such an error of diagnosis, it is generally also accompanied by some temporary accumulation of feces, or by an accumulation of fat in the mesentery and abdominal walls. Hysterical persons are most subject to it. The tympanitis may not necessarily be intestinal, for if the case of M. Josaf, ("Thèse de la Tympanite, 1840,") be not an example of idiopathic peritoneal tympanites, in the rigorous expression of the term, it leaves no doubt as to the possibility of the production of gases in the peritoneal cavity from decomposition of substances effused in its cavity. Other cases are scarcely to be depended upon, for in the best authenticated, such as those mentioned by Combalusier, a mass of hydatids was present in the peritoneal cavity; and that related by Dusseaux ("An. Jour. de Med. Chir. and Phar., tom. li., p. 308, 14, anno 1779) leaves one in doubt of the seat of the pneumatose, whether the intestines or the peritoneum; but whether in the one or the other is a mere object of scientific precision, for its diagnosis with ovarian tumours is equally easy.

How can this error be prevented?—Resonance on percussion may be considered almost an infallible sign because it is only in very rare and evident cases of ovarian disease, that air is introduced into or generated in an ovarian cyst. But in the re-

corded instances of tympanites being mistaken for ovarian tumours, the practitioner was aware of the evidence of tympanites, but he believed that in addition to the distension of the intestines by air there was also some morbid tumour to produce an extensive abdominal swelling. Before examination therefore, it is very important to empty the bowels by a brisk purgative, to give the patient a thorough cleansing out and flushing by Dr. Burns's injection tube, for diarrhoea may coexist with stercoral tumours; the liquid faeces have been known to pass through a tunnel made in the solid faecal tumour, or else between the tumours and the mucous membrane of the intestine. A course of tonic medicine should be given to correct that state of the mucous membrane which causes the stomach to generate wind; ten grains of inspissated ox gall, given every night, has been known to produce the desired effect, and an abdominal bandage will also help the effects of medicine. If the patient be repeatedly examined during this course of treatment, all opportunity of mistake will be avoided. In the same way we have seen a supposed case of ovarian dropsy cured by repeated doses of castor oil. Valsalva and some other writers have seen the stomach so enlarged and distended as to come down within a short space of the pubes, but this could not lead to any error of diagnosis, for the variability of the dimensions of the tumour, its dull sound after repletion, and the extent of tympanitic sound when the stomach is without food, must prevent any mistake.

(1) *Cancerous and other Tumours of the Intestines might be mistaken for Ovarian Tumour.*

Thus Munro (secundus) removed from the colon of a woman an intestinal concretion weighing four pounds, and similar cases have been met with. Cancerous tumours of the intestines are unfortunately still more frequent, and their central position, and their being moveable and surrounded by intestines may lead to an erroneous view of the case.

How to avoid Mistakes.—The implication of the intestines by such tumours gives rise almost always to a frequency of gastro-intestinal symptoms which are not often met with in ovarian disease, vomiting or nausea, deranged digestion, colics, alternate constipation, and diarrhoea are met with, and if the tumour be of long standing, other suspicious tumours may be met with in other regions, and the patient may likewise present the yellowish hue peculiar to those who suffer from that constitutional disease; but in some cases it will still be difficult to distinguish the tumour from the hard irregular ovarian tumour.

(2) *Ovarian Tumours have been confounded with Hernia.*

Case.—A woman, 72 years of age, known to have umbilical hernia, was suddenly taken with abdominal pain and with frequent vomiting. There was also constipation and meteorismus, the pulse was frequent and small, and the features choleraic. As usual, the hernial tumour could not be reduced, but it was soft and

without pain. Many of those consulted proposed *le debridement*, but this was rejected by the majority. The next day the patient died, and on opening the body M. Goyrand found that she had died of acute peritonitis, caused by the rupture of an ovarian cyst, and the effusion of its contents into the peritoneal cavity. ('Vidal Patho. Ext., tom. iv., p. 580.) We have already related a still more interesting case, wherein a prolongation of the ovarian cyst descended into the crural space, and wherein alarming symptoms of intestinal obstruction would have justified the operation for hernia. Such case, by the peculiarity of the symptoms as well as by their extreme rarity, must always puzzle the most intelligent.

11, York Street, Portman Square,

[To be continued.]

CASE OF CANCRUM ORIS,

WITH NECROSIS OF A LARGE PORTION OF THE INFERIOR MAXILLARY BONE, FOLLOWED BY RECOVERY.

By T. HERBERT BARKER, M.D., LOND.,

FELLOW OF THE ROYAL COLLEGE OF SURGEONS.

JOSIAH HILL, of Cope, near Bedford, aged five years and a quarter, was recovering from typhus, which had attacked several members of the family, when a swelling of the right cheek made its appearance, rapidly increasing, and becoming red, hard, and shining. The swelling was the most prominent and tense in the lower part of the cheek, opposite the lower jaw; and the surrounding oedema extended to the nose, right eyelids, (which were closed,) and to the right ear. On examining the interior of the mouth, which was done with some difficulty, owing to the swelling, irregular and jagged ulceration of the cheek and gum was observed, at a point corresponding with the central hardness, and covered with a dark-coloured shreddy slough. On the third day a bright red spot appeared externally in the centre of the swelling, which speedily assumed a purplish hue, and the cuticle became raised by a sanious fluid underneath. At this period there was considerable foetor of the breath, and a flow of offensive saliva from the mouth. The skin was hot, the pulse quick, thirst urgent, and the patient was delirious at night. The central livid spot increased rapidly in size, and on the sixth day was larger than a crownpiece, circular, and with a deep-red colour of the surface surrounding it. On the seventh day a line of demarcation could be detected, and a small quantity of foetid discharge escaped from the slough, which gradually began to separate at its edges. The saliva, which had hitherto been pale, now became of a dirty-brown colour, and extremely foetid, so that the room was scarcely tolerable. The slough gradually loosened, and came away on the sixteenth day, when a large surface of the inferior maxillary bone was found to be denuded, and of a brownish colour. The surrounding oedema gradually subsided, and the febrile symptoms gave way

to those of extreme exhaustion. The large opening through the cheek began to contract in a few days, and the edges to look cleaner, and to be covered with healthy granulations. An offensive discharge continued to flow from the mouth, as well as from the opening in the cheek. In five weeks from the commencement of the swelling, the opening through the cheek had contracted to the size of a shilling, through which the denuded bone was still visible. Soon after this period the patient directed my attention to a jagged edge of bone within the mouth, which appeared just to the right of the symphysis of the lower jaw-bone. The right half of the inferior maxillary bone appeared to be somewhat raised above its natural level, but was not very moveable. This jagged edge of bone became more prominent, and somewhat looser, from day to day; it caused some inconvenience to the tongue, prevented him from closing his mouth, and it was with some difficulty that he could be fed with a teaspoon. In eight weeks from the commencement of the disease it was sufficiently loose to enable me to extract the entire piece of bone. After the separation of the bone, the opening through the cheek gradually contracted in size, and cicatrized, leaving a deep depression, capable of admitting the end of a finger. The necrosed portion of bone is nearly two inches in length, and consists of so much of the body of the inferior maxillary bone as contained five of the temporary teeth on the right side. Two of the permanent teeth, (the canine and first molar,) may be observed, just projecting into the sockets of the temporary teeth. The necrosed portion separated from the living bone anteriorly, just external to the central incisor tooth, and posteriorly immediately behind the last temporary molar tooth, and in front of the ramus of the jaw.

The treatment pursued was the assiduous application of warm fomentations in the first instance, and, on the appearance of the gangrenous spot, of carrot poultices. After the separation of the slough, weak sulphate of zinc lotion was kept applied, by means of lint, covered with oiled-silk, and the edges were touched from time to time with the nitrate of silver. Quinine, and afterwards the carbonate of ammonia, were administered internally, and a liberal supply of strong beef-tea, mutton, broth, and wine, was allowed.

The present appearances of the patient, (five years after the separation of bone,) are the following:—

Externally, a deep cicatrized depression is observed, the site of the original slough; the angle of the jaw on the right side is observed to be an inch and a half nearer the symphysis than on the left side, which gives that side of the face a somewhat contracted and oblique appearance.

Internally, on the right side, only one tooth is observed—namely, the central incisor, which is somewhat below the level of the incisor of the left side; the space between this and the ramus of the jaw is occupied with a narrow line of new bone, which has been thrown out between the two points, and covered with a mucous surface. Mastication is performed efficiently on the left side.

Remarks.—This case corresponds with the second variety of cancrum oris described by Dr. Cuming in the fourth volume of the "Dublin Hospital Reports," and is interesting in consequence of the extent of the disease, and of the necrosis and separation of bone, followed by recovery. Dr. Cuming says, that in every instance that he had met with, this disease had occurred when the constitution had been debilitated by the existence of previous and protracted disease. Dr. Marshall Hall also states, in the fifteenth volume of the *Edinburgh Medical and Surgical Journal*, that in all the cases which had come to his knowledge, it had been preceded by fever, acute disorder of the digestive organs, typhus, inflammation of the lungs, variola, rubeola, or scarlatina, and regards it as a consequence of the exhaustion, debility, or irritation produced by previous disease.

In three other cases which have come under my notice, two occurred after typhus, and one as a sequela of scarlet fever. In every case the mucous membrane was the first attacked, the sloughy ulceration within the mouth having been observed before the external gangrenous spot made its appearance, thus confirming the views of Dr. Cuming, and of MM. Rilliet and Barthez, Baron, and Dr. West, referred to in the excellent "Lectures on the Diseases of Children" by the last author,

All the cases occurred at or about the same age; and two of them terminated fatally with low fever, diarrhoea, and exhaustion, before any line of separation of the gangrenous portion had formed. The other case of recovery was one in which the upper jaw was involved in the disease; and a portion of bone, containing a primary molar tooth, came away through the ulcer in the cheek, leaving a permanent and unsightly cicatrized depression.

In consequence of some resemblance of these cases to the ulceration and inflammation of the mouth produced by mercury, they have frequently been attributed to the administration of that drug; but from the number of cases which have occurred where mercury had not been given, there can be no doubt that there is not necessarily any connection between the two, and certainly this remedy had not been used in any form in the cases under my notice. It may be remarked, that cancrum oris is confined to one side of the face, whereas, from the use of mercury, the gums of both jaws are affected, as well as on both sides. The fœtor, too, produced by mercury, is very different from the highly-offensive and putrid odour of cancrum oris—a difference readily recognised by any one who has noticed the fœtor from both causes.

With regard to the treatment of cancrum oris I have nothing more to state, than that I am inclined rather to have recourse to fomentations, poultices, and the nitrate of silver, than to the strong acids which have been recommended by some practitioners. Internally the cordial and tonic plan of treatment is clearly indicated.

Bedford, September 8, 1852.

CASE OF ABSCESS OF THE RIGHT OVARY

TERMINATING IN RUPTURE INTO THE PERITONEUM AND
DEATH FROM PERITONITIS

By WILLIAM DAVIES, M.D., BATH.

Read before the Bath and Bristol Branch of the Association, October 7, 1852

JULIA REEVES, a prostitute, 21 years of age, was brought to the United Hospital, on the 10th of last September, and admitted an in-patient under my care. She stated that she was taken ill on the morning of the 7th with severe pain in the belly, attended with sickness and vomiting. She had rigors, followed by a hot skin and great thirst. There had been no action on the bowels since the day before her attack—that is to say, the 6th. The urine was very scanty and high-coloured. At the time of her admission her appearance indicated great suffering and distress; the countenance had a pinched anxious look, with considerable flushing of the cheeks; the pulse was frequent and feeble—110 to 120; the tongue was moist, and covered with a thick yellowish fur; the skin was cold and damp; the lower limbs, from the knees downwards, and the hands, of an icy coldness; the breathing was short, quick, and entirely thoracic. She lay on her back, with the body raised, and the limbs stretched out. The belly was tense, tympanitic, and not remarkably intolerant of pressure. There had been no sickness for two days previous to admission.

She was ordered half an ounce of castor oil and five minims of laudanum; an injection of thin gruel, with an ounce and a half of turpentine, to be thrown up two hours after the oil; the belly to be diligently steeped with hot flannels sprinkled with turpentine; warmth to be applied to the extremities, and small quantities of arrowroot to be given at short intervals. Directions were given that if the oil was rejected no further aperient was to be administered, but simply one grain of solid opium to be given every three hours. Should the bowels be relieved by the oil, the opium was to be given immediately thereafter.

I saw her again in the evening. The bowels had been freely moved after the injection, and she had taken one opiate pill. She expressed herself as feeling better; it was, however, quite obvious that she was worse. The countenance looked more pinched and sunken; the pulse was feeble, although some degree of warmth had been restored to the extremities. The opium, with the turpentine steeping, were ordered to be continued, with the arrowroot. There had been no sickness.

11th.—She had passed a tolerably comfortable night, though all the objective symptoms were more unfavourable. The same treatment was continued, with the addition of some wine, and afterwards brandy, in spite of which she sunk gradually during this day and the next, and died from asthenia, death beginning at the heart, on the evening of the 12th (Sunday).

The body was examined thirty-six hours after death. On laying open the cavity of the belly, the usual appearances of the most acute peritonitis were presented, gradually diminishing in intensity from below upwards. Each knuckle of intestine was agglutinated to its neighbour by recently-effused lymph, while the great omentum was glued down to the bowels by a thick layer of what looked like half-solidified honey. There were two or three pints of a puriform fluid with a quantity of flaky lymph floating through it in the cavity. On stripping the layers of lymph off the peritoneal covering of the bowels, the most intense capillary injection of the vessels was observed. The uterus and left ovary were healthy in structure, but the right ovary presented a ragged opening, leading to the irregular walls of an empty abscess, which had evacuated its contents into the sac of the peritoneum, and which had, no doubt, been the immediate cause of the fatal inflammation of that membrane. The organs within the chest were healthy. The head was not examined.*

Remarks.—Abscess of the ovary is a somewhat rare affection, and when it does occur, nature is generally too wise and too careful to allow such an accident as the one I have detailed to happen. Most frequently the serous covering of the ovary becomes inflamed during the progress of the case, and adhesion takes place between it and some neighbouring part, by which, when the abscess does burst, the pus is prevented from making its way into the general peritoneal cavity.

As to the diagnosis in this case, it was very clear that we had one of two things to deal with—either peritoneal inflammation or obstruction of the bowels, most likely ileus. The history of the case, such as could be obtained, rather pointed towards the latter conclusion. There had been no action of the bowels during four days. The attack had commenced with much pain and vomiting. When first seen by me there was no remarkable tenderness on pressure, while there was great distention of the belly. Under these somewhat doubtful circumstances the castor oil and the enema were ordered, whereas, had I been sure that I had a case of unmixed peritonitis to contend against, I should have commenced the opium treatment at once, without any attempt to act on the bowels. Any form of blood-letting seemed out of the question; besides which, had there been more vital power, the period for the advantageous use of that remedy had, in a great measure, passed away, as indeed had all hope of a favourable termination from any kind of treatment.

October, 1852.

* The uterus, with the diseased and healthy ovary attached, were exhibited to the meeting.

Proceedings of Societies.

SOUTH-WESTERN BRANCH.

THE DRAFT MEDICAL BILL.

REPORT OF THE COMMITTEE OF THE SOUTH-WESTERN BRANCH OF THE ASSOCIATION ON THE AMENDED DRAFT BILL.

At the annual meeting of the South-Western District Branch of the Provincial Medical and Surgical Association, held in Exeter on the 13th of August last, the amended Draft Bill, "To produce uniformity of Medical Education and Qualification, and for the Registration of those Licensed to Practise in Medicine," as printed in the *Journal* on the 12th May last, was very fully considered; and as many weighty objections to this measure were then entertained, it was resolved unanimously (especially as this Draft Bill had received the general approval of the annual meeting of the Association at Oxford) to appoint Dr. Pennell, Dr. Shapter, Mr. Barnes, Mr. James, Mr. Delagarde, and Mr. Pridham, a Committee by whom these objections should be duly set forth and submitted to the Central Council for its consideration.

In compliance with the above resolution the Committee begs respectfully to submit to the Central Council the following report.

That the 3rd clause of the Draft Bill is deemed objectionable, because in the appointment of the Medical Council for England no adequate representation of the provincial medical practitioners is ensured, since it neither directs the appointment of any provincial medical practitioners, nor, should such be appointed, (as perchance they might be amongst the number to be chosen by the Secretary of State, or by the College of Physicians, or College of Surgeons,) are the extraordinary expenses, necessarily consequent upon their attendance at the meetings of this body, provided for. The circumstances of medical men practising in the country districts of England widely differing from those of medical men practising in the metropolis, renders it essential to the good government of the profession at large that these former should, in some sort, be represented in the ruling body.

This clause is also objectionable from its entirely passing by all consideration of, and representation by, the Company of Apothecaries; such omission is neither courteous to this Company, which, as the great licensing body of the country, has striven, and most successfully, during many years, to elevate the professional character and social position of the medical profession, nor just to that large body of general practitioners who thence derive their credentials and legal right to practice.

That the 12th clause is objectionable from its not sufficiently securing the monies to be derived directly from the whole mass of the profession; these being, as the clause now stands, vested solely in the Council instead of in trustees thereto specially appointed, and separate from the Council and Examining Board.

This clause is also objectionable from its not suffi-

ciently defining the duties of the Treasurer, nor making provision for the periodical auditing and publishing of the accounts whereby the public may be informed of the monies received, whether by fees, or fines, and of the monies, whether by salaries, or otherwise, ordered to be paid.

That the 14th clause is objectionable, inasmuch as, while (together with Schedule B) it confers the name and title of a Licentiate in Medicine," and grants a "licence to practice medicine" with the express statement that the person so designated and so licensed is "duly qualified to practise medicine," both the title and the licence to practise are, by subsequent enactments of the Bill, (*vide c. xvii. with Schedule C.*) practically set aside.

That the 15th clause is objectionable, as well from its enforcing that of the "four years" to be applied to the study of medical and surgical science "at least three years shall be passed in some University or medical school," as from its omitting to direct previously to the commencing of this required collegiate education some time or form of studentship, together with a matriculation examination, whereby the possession of a previous sufficient elementary medical and general knowledge may be ensured.

This clause is also objectionable from its neither recognizing nor giving any special privilege to the extensive means of education afforded by provincial hospitals, with the exception of those few to which "medical schools" may be attached.

The effect of the above enactment and of these omissions cannot fail eventually greatly to retard the attainment of sound practical information, as well as to be prejudicial to the personal interests of the profession at large. Medical education will thus be virtually, if not actually, transferred to the "Universities," or "medical schools," to the subversion of that excellent and extensive means of practical medical instruction afforded by pupilage in provincial hospitals and apprenticeship under private practitioners, which has so long existed, and which has mainly contributed to form the useful and intelligent class of medical men now practising throughout the country. Doubtless "universities" and "medical schools" are most admirably adapted to convey information in medical science, but they must not be deemed the only sources whence early medical information is to be obtained, and if relied on solely, or even mainly, will fail to produce a useful and practically instructed class of medical men, trained to those habits of business which in the general private practice of this country are no less indispensable to the success of the practitioner than to the safety and satisfaction of the sick he has in charge.

There are also other evils likely to proceed from the exclusively university education. Youth will thus, on the one hand, be too early thrown amongst the excitements of large cities; and, on the other, the cost of this protracted course of a necessarily expensive education may prove so onerous as to render difficult an adequate supply to the country of medical practitioners, while these, having received an extended scientific education, and such as is well adapted, after subsequent practical experience, to form very accomplished physicians and surgeons, will generally be unwilling, or

even perhaps unable, to fulfil the more ordinary and casual requirements of the great mass of the population, and will, moreover, reasonably seek a sphere of utility in other than the more distant and less populous parts of the kingdom where practice is laborious and remuneration inconsiderable. The wants of the public being thus unprovided for, cannot but prove the means of developing a class of irregular and illegal practitioners. In fact, these disadvantages, and from the same cause, are at this very time, to a certain extent, being experienced in the country districts of England.

The 16th clause is objectionable by its withholding from the Council, at its triennial medical congress, all power of altering or modifying that enactment (of the 15th clause) whereby a candidate for the licence to practise shall have "applied himself to the study of medical and surgical science during a period of four years, and that during the aforesaid period the student has passed at least three years in some university or medical school;" it being more than probable (for reasons now stated) that this enactment will prove to be injurious to the interests both of the public and of the profession.

That the 17th clause is objectionable from its peremptorily obliging those who have been examined and licensed by the Council (under the 14th clause) to undergo, in order to registration, a further examination by the College of Physicians or by the College of Surgeons; especially as the Bill in no way provides that these bodies shall be satisfied with the "curriculum" prescribed by the Council as necessary to their own examination. Moreover, by forcibly obliging the "Licentiate in Medicine" to attach himself to one or other of these bodies, it subverts the usage of this country, which has established, both nominally and practically, three divisions of the medical faculty, viz., the general practitioner, the surgeon, and the physician.

This clause, besides rendering those previous clauses of the Bill relating to examination and the "licence to practise" of no practical utility, entirely sets aside that common-sense proposal developed in the Bill formerly framed and "brought in" by Sir James Graham, viz., that, after the completion of a certain course of instruction, and after an examination by a joint board of physicians and surgeons which should qualify for practice, the practitioner so qualified might, after further prescribed study, resort to the College of Physicians, or to the College of Surgeons, and so, after adequate examination, proceed to a higher grade in the profession.

Again, this clause is objectionable from its omitting in any way to allude to or to define the position of those who may in after years have medical degrees conferred on them by the English or other Universities. The degrees thus derived are treated by this proposed Bill, apparently as regards title, and certainly as regards qualification, as worthless; those holding them being actually disqualified from practice unless they shall be registered under this Bill, which can only be effected after an examination by the Council and by the Colleges of Physicians or Surgeons.

The most valid reasons should be assigned for thus obliging, on the one hand, the Bachelors and Doctors in Medicine to undergo these further examinations by

the Council and by the Colleges of Physicians or Surgeons, and, on the other, for withholding the privilege to practise from those whose competency the Council has itself, by its Examining Board, affirmed, and to whom its licence has accordingly been granted.

On reviewing the whole bearings of this clause, it cannot but be regarded as anomalous and unjust; and though its provisions may probably be a means of averting opposition to the Bill generally on the part of the College of Physicians or Surgeons, by guaranteeing to these bodies their present or an increased source of income, yet this will be done at the expense of the future candidates for practice.

That the 18th clause is objectionable, from its obliging medical practitioners annually to apply, and to pay for, the certificate.

That the 19th clause, wherein is directed that "one-half of the monies received on account of the certificates shall be applied to the formation of a Medical Provident Fund," is objectionable in principle, from its making the contributions to a charitable fund compulsory.

J. SHAPTER, M.D., CHAIRMAN,

Physician to the Devon and Exeter Hospital.

RICHARD LEWIN PENNELL, M.D.,

Consulting Physician to the Devon and Exeter Hospital.

SAMUEL BARNES, F.R.C.S.E.,

Consulting Surgeon to the Devon and Exeter Hospital.

JOHN HADDY JAMES, VICE-PRESIDENT,

P. C. DE LA GARDE, F.R.C.S.E.,

One of the Surgeons of the Devon and Exeter Hospital.

EDWARD P. PRIDHAM, F.R.C.S.E.,

Consulting Surgeon to the Exeter Dispensary.

Exeter, October 28, 1852.

[It will be seen that the greater part of these objections have already been met by the alterations made in the Amended Bill, published in our last number.—Ed. J.]

EAST KENT & CANTERBURY MEDICAL SOCIETY.*

Cancer of the Pylorus, Peritoneum, Cæcum, Colon, Omentum, and Pleura.—By Dr. GOOCH.

J. R., aged 60, was admitted into the Canterbury Hospital, February 7th, 1851, in a state of extreme wasting, having for two months rejected every meal, sometimes a few minutes after eating, at other times not for five or six hours. He had several times vomited copiously a fluid of the colour of coffee-grounds, and as frequently a colourless fluid, like that rejected in pyrosis, intensely acid. Severe pain in the stomach preceded each fit of vomiting. No tumour could be felt in the epigastrium. The abdomen was much retracted. He had a clean tongue, which was deeply fissured, but not red or glazed. There had been frequent slimy alvine discharges. The urine was

* Continued from page 195.

scanty, and sedimentous, but acid. Pulse 74, small and feeble. Heart sounds natural. The countenance retained its natural deep-red colour, with no dingy sallowness about it.

He was treated by leeches, blisters, prussic acid, and creasote, with lime-water, at first with relief to the pain and vomiting, so that he could bear a little food; in a day or two, however, he relapsed, looked more worn in the face, and became at times a little delirious. After slight fluctuations of strength and gastric suffering, he died on the eighteenth day after his admission.

Post-mortem appearances.—The body emaciated, and devoid of fat. An irregular, puckered, indented cicatrix over the middle portion of the sternum, to which it was intimately connected; this was evidently the trace of old ulceration of bone which had healed. However, the bone under this cicatrix was enlarged, and its cancellous structure occupied by soft medullary substance, which could be readily turned out by the handle of the scalpel; some part of this substance presented a semitransparent appearance, and resembled beef-jelly in colour and consistence. A firm carcinomatous mass enveloped the pylorus, and matted together the surrounding tissues and neighbouring organs; the pancreas was imbedded in it, but was healthy. This morbid growth extended along the walls of the stomach for a couple of inches, and the surface, which slightly projected into the cavity of the stomach, was ulcerated over the greater part of its extent. A section of the disease exhibited the usual appearances of hard cancer. The cardiac portion of the stomach was so digested by the action of the gastric juice, that the coats gave way in lifting it from its position. A portion of the lower part of the duodenum adhered firmly to the pyloric end of the stomach, and it was found that the disease had advanced into the coats of the bowel. Firm cancerous tubercles, of various size, were scattered over the whole surface of the peritoneum; and in some places, especially around the organs in the pelvis, they were aggregated so as to form large masses, which adhered firmly to similar masses developed on other organs, so as to fix them closely together. And further, this diseased structure penetrated these organs from without, and could be traced in several stages invading their coats and tissues. The omentum was converted into a finely lobulated mass, which was puckered up, and adherent to the ascending colon; at the point of contact a deposit of cancer existed, which involved the entire thickness of the coats of the bowels. The solitary tubercles were flattened discs, vascular around their margins, and causing the neighbouring tissue to be somewhat contracted and puckered. A deposit of cancer was noticed at the ileo-cæcal valve, including the neighbouring portions of the ilium and cæcum. Several cancerous tubercles were formed on the pleural surface of the diaphragm and the contiguous surface of the lung. All the other organs were healthy.

Softened Tubercle in a Fallopian Tube, communicating with the Vermiform Process of the Cæcum, and a softened Bronchial Gland Ulcerating into the Esophagus and Right Bronchus, in the same subject.
—By A. B. ANDREWS, Esq.

E. B., aged two years and a half, having dark hair and eyes, and long eyelashes, was quite healthy till September, 1849, when she was about a year old. She was then attacked with hooping cough, which was not severe, subsiding before winter; a cough, however, continued, and the child did not gain strength, remaining feeble and emaciated, with a relaxed state of bowels, which at times was considerably aggravated. In August, 1850, the diarrhoea became more severe, and symptoms of dysentery appeared:—constant straining, with frequent scanty mucous stools, streaked with blood; red blood alone occasionally passing. Under treatment these symptoms improved, but recurred and continued more or less until she died. She lost appetite, and became very emaciated. About a fortnight before death, she was attacked with vomiting, became exceedingly low, lying in bed, and not liking to be disturbed, or to have her head raised. The day before she died a quantity of blood flowed from her mouth. The cough was present during her whole illness, and her hand was frequently placed upon her right side and over her abdomen, apparently from pain in those parts. There was latterly a coloured discharge from the right ear. Two children of this family had died with disease of the bowels, one at fifteen months, the other at thirteen months.

The body was examined three days after death. The *post-mortem* rigidity was absent, the muscles of the abdomen having a slight greenish tinge. The body was greatly emaciated, the outline of the intestines being visible through the abdominal walls. Small, scrofulous tubercles, many of which presented a vascular appearance, were scattered over the surface of the peritoneum, of the parietes, and of the viscera. The small intestines were agglutinated together, and on their surfaces, and in the uniting medium at the situation of these adhesions, there were numerous small tubercles the size of hemp-seeds. Some of these could be readily detached from the lymph in which they were deposited. Several fine filamentous bands of lymph extended between various parts of the intestines; and in a few of these there were tubercles, looking like beads on a string. Both in the large and small intestines there were numerous scrofulous ulcers. The organs in the pelvis were found fixed together in the same manner as the intestines. The ovaries and the fallopian tubes were much enlarged, and were infiltrated with tuberculous deposit. The fallopian tubes were as large as quills, and were much distorted. The right fallopian tube had become adherent to the vermiform process of the cæcum, into which there was an ulcerated opening, communicating with the softened centre of the tuberculous deposit. The lungs were adherent to the chest, and presented numerous patches

of tuberculous deposit, and cavities, in various stages of progress. The bronchial glands were infiltrated with tubercles; and one larger than the rest had softened, and formed two fistulous passages, one opening into the œsophagus, the other into the right bronchus.

Purpura of the Lungs in a Child affected with Hereditary Syphilis.—By A. B. ANDREWS, Esq.

A male infant, six weeks old, weighing at its birth 10lbs., two days after it was born had purulent ophthalmia, which continued for a month. About the second week an herpetic eruption appeared on the face; at the same time one of the thumbs was scratched near the nail, inflamed, and ulcerated, the nail being destroyed. The other thumb ulcerated without apparent cause, and the nail was also destroyed; the ends of both thumbs remained considerably enlarged. Before the eruption on the face disappeared the fauces and nares became inflamed; a slight discharge issued from the nose, the fauces were congested, and the child breathed entirely through the mouth. The child was very fretful and restless, and gradually dwindled to a mere skeleton.

The mother is a stout plethoric person, and very irregular in her habits, being little else than a prostitute, though married. She has had syphilis in its primary and secondary forms. She has had seven children, of whom only one survives. One child died rather suddenly with symptoms of disease of the head; the other children became gradually emaciated and died.

Post-mortem examination.—The body was very emaciated; the outline of the intestines was delineated on the surface of the abdomen. A few small purple spots were observed in the skin of the arms; none were observed elsewhere; and it was difficult to determine that they were not the remains of flea-bites. There was an absence of fat in all the tissues. The uvula, fauces, and posterior nares were purplish from congestion; this appearance terminated about the glottis. The mucous membrane was not softened or ulcerated. The heart was natural; the foramen ovale was patulous by a valvular slit at its margin, which would admit a large probe; the ductus arteriosus was corrugated and contracted, but pervious. The lungs (more especially the left) presented on their surfaces numerous spots of purpura, varying in size and form; some of them seemed limited to one lobule of the lung, whilst others occupied several; in many the colour diminished in shade towards the margin; the surface of the lung was neither raised nor depressed by these spots, which felt slightly firmer than the surrounding natural tissue of the lung. On making a section of the lung, the deeper tissue was found more extensively discoloured by blood, but still presented a more or less patchy appearance; in the posterior portion of the lower lobes, especially the left, it was difficult to determine that the appearances were not due to an early stage of pneumonia. The trachea and bronchi were natural. About the centres of the upper and lower borders of

the greater numbers of the ribs there were streaks of ecchymosis, some nearly an inch long, which being broad in the middle, tapered to the ends; those placed on the upper margins of the ribs were the largest. The abdominal organs were healthy, and no spots of purpura or ecchymosis were noticed anywhere else.

A Foreign Body declared by a Patient to have become Lodged in the Trachea, and extensive Follicular (?) Ulceration of the Œsophagus discovered,—post-mortem.—By A. B. ANDREWS, Esq.

R. B., aged 84, singular and irregular in his habits, said that twelve months before his death, which occurred on the 19th of March, 1851, that whilst eating some cherries from some cherry brandy, he accidentally swallowed a cherry-stone, which went into the windpipe. Although, from the absence of any peculiar symptoms, he was informed of the improbability of the occurrence, he always maintained his assertion. He experienced uneasy sensations about the throat, which he referred to the presence of the stone; and he often declared that he could feel it in certain parts of his throat. He had a cough, and for some period before his death he hawked up a purulent fluid. On February 19th he was attacked with erysipelas of the foot, from the effects of which he died. In fulfilment of his own request, his body was examined, in order to search for the cherry-stone.

The trachea, bronchi, and lungs were carefully examined: they were healthy, and contained no foreign body. Some long bands of adhesion existed between the pleural surfaces of the right lung. The œsophagus contained some thick muco-purulent fluids, and, from a point just below the termination of the pharynx, to the cardiac orifice of the stomach, was studded with numerous ulcers, most of which were small, had sharp, irregular, abrupt edges, and completely penetrated the mucous membrane; they appeared as if pieces of the membrane had been punched out. The larger ulcers seemed to be formed by the coalition of the smaller ones. The stomach was free from ulceration, but presented several isolated, irregular patches, of vascularity; so intense in some instances as to convey the idea that blood was effused under the mucous membrane. The man had been noted as a great beer drinker during life.

Hydrocephalus, with Spina Bifida.—By MR. RIGDEN.

A female child was born, with the above deformities, April 18th, 1851, being the fourth child of its parents. All the other children had been born healthy, and well developed. The father, soon after his wife had conceived with this child, became afflicted with ascites, from diseased liver, and the mother throughout her pregnancy had been much disposed to dropsical effusion. Both parents are temperate in their habits, and are water-drinkers. The child, when born, though otherwise plump and well-developed, presented a large head, and a spina bifida, about the size of an egg, in the

lumbar region; it was not very prominent, and was covered with thin skin having no cuticle. There was paralysis of the bladder, and of the lower extremities. The child took the breast, and other nourishment, well, but continued to lose flesh, whilst the head increased considerably. The only change that occurred in the tumour of the loins, was an alteration in the appearance of the surface, so that it seemed to be covered with a more natural integument. When the child was about six week's old, a puncture was made with a common needle into the anterior and posterior fontanelles, and also into the sac of the spina bifida; about two ounces of serum escaped, with no apparent benefit to the child. The parents would not allow any other treatment to be pursued, and the child died at the age of ten weeks.

Post-mortem examination.—The bones of the head were separated by considerable intervals, and the entire head was soft and fluctuating. In removing the calvarium the brain was injured, and a large quantity of straw-coloured fluid escaped. The arachnoid appeared natural. There was no trace of the convolutions of the brain, which were flattened out into a uniform surface. The lateral ventricles were dilated into one large sac; a trace of the prominence of the corpora striata, and a still slighter one of the thalami optici, were all that could be distinguished of the objects usually seen. The membrane of this sac was much thickened, soft, puckered, and flocculent. The cerebral substance surrounding this sac was a quarter of an inch thick. The spina bifida occupied the whole lumbar region. There was a fissure in the posterior part of the spinal canal, which included the last dorsal and five lumbar vertebræ. The membranes of the cord were united into one layer, forming the pouch containing the fluid; and the nerve-trunks, which constituted the spinal cord, were spread out in the sides of the sac. There was no lumbar plexus found on dissecting into the psoas and quadratus lumborum muscles; but two or three filaments, which might have represented some of the cutaneous nerves of the abdomen, were found, and branches of the sympathetic nerves could be traced uniting with them at the point where they issued from the spinal column.

BIRMINGHAM PATHOLOGICAL SOCIETY.

JULY 1ST, 1852.

GEORGE YATES, ESQ., IN THE CHAIR.

A very Remarkable Series of symptoms of Disordered Circulation, and finally of Disorder of the Nervous System, from Degeneration of the Heart.—By Dr. RUSSELL.

Miss P., aged about 60. I was called to her about February 9th, 1852. She had been seized with a very severe attack of dyspnoea just after she had gone to bed, before going to sleep. The weather was cold, and

she had no fire in her chamber, and had gone to bed without having her bed warmed, as was her custom. At the time I attributed the occurrence of the attack to this circumstance. I saw her in about half an hour afterwards. She was sitting upon the bed, leaning upon a friend, in great alarm, anxiety, and distress, breathing rapidly and with difficulty, but entirely free from anything like asthma; her breathing gave me the idea of air not passing through in sufficient quantity, or with sufficient rapidity. Her pulse was rapid, quite regular, and remarkably firm and resisting. Her extremities were cold; her face and fingers livid; the veins of her neck were distended with blood. She was perfectly sensible, and had no pain. Though her state was then so alarming, it had been much worse; she was then in process of recovery. The attack set in with severe palpitation, which lasted for five minutes. There was some crepitation at the back of the chest, but no sibilus nor other unhealthy sound. The attack subsided very gradually. She coughed several times, and expectorated mucus, with some blood. Next morning at ten she was coming down stairs, and was pretty well. The present was not the first of her attacks: the first one occurred last April; it came on without warning as she was walking in heavy rain and high winds. It was not very severe, though she was obliged to go into a house for a short time. The second was about three weeks after; it occurred (as did all the subsequent ones) while she was in bed. She was free from them during the summer; but they returned in November; and the first she then had was of great severity. The weather was very cold. After another less severe, there was none of importance until the present one. Her breathing, however, was easily affected; she could not meet the wind; and she found that her breathing was affected if she mounted the stairs before breakfast. She has been obliged to confine herself to the house from this circumstance for the last two months. In December I examined her chest carefully, but could not detect anything wrong. She was under the constant care of my father. She is of spare habit, of a nervous temperament, has a pale complexion, is easily apprehensive and depressed. She has no arcus senilis, but her right eye has an opaque white semilunar band, about a line and a half broad, at the upper and lower edge of the cornea. Her health has been good, excepting that a few years ago she ruptured some of the muscular fibres of one leg, which confined her to the house, I believe, nearly two years. On examining her chest, I found no extension of the ordinary cardiac dulness; the first sound of the heart was decidedly feeble and blunt, the second sound was ringing. Respiratory sounds were natural; the carotids, and especially the artery at the wrist, were remarkably tortuous.

February 12th.—Face beginning to lose its dusky tinge, the remains of the last attack. Her pulse was still quick; it had a remarkable degree of resisting power, which particularly attracted my attention, in contrast with her feeble and distressed state. Two blisters had been applied unsuccessfully; I now tried a

third. Sum. ter die.—R. Tinct. Ferri. Sesqui.-Chlor., gttss. v., to be gradually increased. Nutritious diet, two glasses of sherry, and a fire in the bedroom.

13th.—The third blister did not rise. Pulse unchanged; same lividity; she is very low and depressed. Continue medicine.

20th.—She has been slowly improving, and as she mends her pulse becomes softer. Eats and sleeps well.

24th.—Another attack last night. It came on with oppression; then a rattling in her throat, and violent retching to expel mucus. She expectorated a good deal of mucus. The fit subsided, with copious and frequent micturition, and large development of flatus. My friend, Mr. Simons, who saw her, described the fit as having been of the most alarming character; he thought she would have died. From the great strength of the pulse, and the very loaded veins, I had ventured to suggest a careful trial of venesection in another attack; this, however, Mr. Simons feared to attempt on the present occasion; and leeches to the root of the throat were found impracticable. This morning she is comfortable; no blueness. Continue the iron.

March 3rd.—Again an attack last night, of less severity, but of longer duration.

9th.—An attack last night. Lately she has been complaining of numbness in her hands. Her pulse still presents the remarkable firmness noticed before.

15th.—Again an attack last night. Every attack leaves her much depressed; and her state of depressed spirits and irritability has been a very troublesome symptom.

I made no particular notes until April 11th. She went on much as before; only able to creep up and down stairs; often obliged to sit up in the night for several hours, from short breath and apprehension of another attack. Appetite tolerable; bowels regular; the face is pale, often much worn, sometimes leaden. I found her urine light-coloured, loaded with pink lithates of natural specific gravity, slightly albuminous, but without any particular microscopic appearance. I have continued a tonic treatment, employing various agents, with ammonia and æther occasionally.

April 11th.—She has had an attack on each of the last three nights. For the last week or two her nights have been much disturbed; she has always had an attack every third night or oftener; and is beginning to suffer from want of sleep. She can scarce move up stairs; the day before I witnessed much distress with pallor and palpitation occasioned by mounting a small flight of stairs. She complains of short breath when swallowing food.

13th.—Last night was the fifth night in succession of the occurrence of an attack. She looks quite ghastly from want of sleep; she can scarcely lie down at all.

15th.—In a most distressing state. A pale anxious face, and great mental depression. Examination of chest and abdomen discovers nothing beyond what is stated above. I have feared to give her opium, from her tendency to lividity, and from the fact that a small dose early in her illness caused unpleasant symptoms. I now, however, began with a small opiate every night.

17th.—No improvement. Quite unable to lie down. She has begun to have oedema of the ankles.—R. Morphia Muriatis, gr. $\frac{1}{4}$, h. s.

18th.—The morphia procured sleep, and she lay down while sleeping; but she is still in a wretched state. She says that the shortness of her breath prevents her from uttering many words in succession. She has not had another attack for four nights, since she begun the morphia.—R. Murph. Mur., gr. $\frac{1}{3}$, omni nocte.

24th.—The oedema has increased very rapidly. No return of her attacks. She has some sleep at night; though, when not under the influence of morphia, she cannot lie down. The aspect of her face has improved considerably.

30th.—Had no opiate last night; she could not lie down all night, and she had an attack whilst dressing. She now remains permanently up stairs. Oedema of the legs very great. Urine as before. In talking she has to pause continually for breath.

May 8th.—Last night she took no opiate, and she suffered from dyspnoea for two hours; her friends described it as panting; it was so bad that she thought herself dying. The opiates produce very unpleasant effects; they give her disturbed sleep, but render her quite delirious. She does the most extraordinary things in the night; and during the day their continued influence oppresses her very much.

16th.—In great distress for breath. She sits in a singular posture, with her head much bent forward, constantly panting. A severe attack of dyspnoea the last two nights. She has given up the morphia, on account of its very distressing effects. Her mental state now assumed a peculiar character, which I will describe in a future report.

18th.—She seems dying. There is much fullness of the veins, but lips not leaden. There is less oppression of the chest. For the last three days her inability to lie down has become peculiarly distressing. She sits up constantly, with her head quite bent upon her chest; she never raises her head when she speaks, and she is fed in this posture. Her neck is quite bowed by her strained position. Yesterday there was a good deal of distress in breathing. To-day Dr. Fletcher saw her with me: he detected nothing further in the state of her chest; he especially noticed the tortuous state of the carotids.

19th.—Sits in her chair night and day, her chin upon her chest. Much less leadenness of her face.

23rd.—She is in a state of extraordinary mental derangement. She has had no opiate since the 14th, on account of the extreme disorder it produced by night; but since the 14th she has been delirious each night, but generally rational by day, though disordered at times. She was, however, possessed with the idea, which she constantly maintained, that she was encircled by a galvanic wire; she several times spoke to me about it, and to-night asked me, with great solemnity, if I believed in galvanism. On the night of the 21st, however, she was violently maniacal; she was possessed with the idea that Dr. Fletcher and myself had engaged some one to destroy her. She shrieked out, drove the

servants away, and clung to her friend, with a face expressive of the wildest horror and affright; her entire behaviour is of the wildest description. She called down God's curses upon her persecutors, and exclaimed that the nurse had called in that horrid form to attack her. She had had less stimulants than usual in the evening, for she had told her friend that she was going mad, and made her promise not to give her brandy, of which she usually took a little three or four times a day, if faint. On the night of the 22nd she took a morphia pill (Morph. Acet., gr. $\frac{1}{4}$); the night was passed in her chair, as were the two preceding ones. During the first part she was in a kind of lethargy; early in the morning she again awoke in high excitement, but now with a strongly religious turn; her mind was occupied with the spiritual world, and through the day she talked continually, and to a great extent coherently, on this subject, and in the evening was running on incessantly in a low voice to one or other of us, holding our hands until we removed them, and whispering in our ears, or writing coherently, though quite irrelevantly, upon paper. There is still a sense of danger in her wanderings. Her posture has undergone a remarkable change; from having been constantly bowed down forwards, she now sits erect when she speaks to us, and looks in our face. Her lips are red, her face pale and haggard, pupils small, eyes not congested, pulse not very feeble. She takes brandy occasionally.—Repeat Morphia.

May 25th.—Yesterday and to-day more quiet, though still deranged; last night her nurse induced her to go to bed; she lay flat all night, and does so now, without the least distress; some sleep in the night; face wild; breathing calm; pulse more feeble, 26; lies quite easy; mind still wanders; sinking,

27th.—No sleep last night; mind more collected; lies quietly; much diarrhoea; no opiate last night.

28th.—In consequence of the diarrhoea, the oedema of the leg which was extreme, has entirely disappeared in the last two days. The diminution began with a copious diuresis, which preceded the diarrhoea. She died on the 30th of May.

Sectio-cadaveris 26 hours after death.—Oedema entirely subsided from the leg; decomposition considerably advanced; emphysematous crackling beneath the skin. Some old and firm adhesions at the apex of each lung, two calcareous masses in the upper lobe of the right lung, each the size of a small hazel nut, they were imbedded in the pulmonary tissue, each surrounded by a thin membrane, from which there was some difficulty in separating them. The apex of the right lung was a little puckered, but there was no appearance of a cavity having healed, nor was there any sign of tubercular disease. In the left lung was one small calcareous concretion, about the size of the millet seed. The pulmonary tissue was very dark throughout, and the lower lobes of both lungs were so loaded with blood, and crepitated so imperfectly, that they seemed to be only prevented from sinking in water by the *post-mortem* emphysema. Bronchial tubes quite healthy. The heart was very much enlarged, but was much covered by the

lungs, which had advanced; it had also sunk so as to occupy a lower position in the chest than natural. The right auricle contained a good deal of blood; the right ventricle less; the left side was empty. The enlargement of the heart was caused principally by the left ventricle, which was partly hypertrophied and considerably dilated. The hypertrophy affected the wall and not particularly the carnea columnæ. The left auricle was also very much dilated; the valves were all healthy. The tissue of the heart had a peculiar colour, which would be imitated by a copious admixture of yellow ochre with light red; it was exceedingly flabby, its state of commencing decomposition forbade an opinion of its consistency. The coronary arteries were in their usual numbers, they were much thinner than usual, and unusually capacious; their openings at the aorta were much thrown into folds. The aorta and its primary branches were dilated, this was especially evident in the carotids, which were much larger than usual, they did not present any appearance of tortuosity. In the abdominal aorta there were two or three patches of atheroma, and one or two large patches of complete calcareous degeneration. There was a sparing deposit of atheroma in one or two of the primary thoracic branches. The pulmonary artery was natural. The liver and kidneys were healthy; all the intestines were firmly bound together by cellular adhesions, evidently of very long standing; I could not learn that she had ever had an attack of inflammation of the bowels.

Members of her family have died of consumption, and a brother of diseased heart, it is stated.

The microscopic examinations were not satisfactory, owing to previous macerations and to the decomposition. The heart was placed at once in wood naphtha, and the examination was of necessity delayed for nearly a month. There was no trace of fat among the muscular fascides. The fascides themselves preserved their usual form unchanged; but there was a marked difference between the tissues of the right and left ventricle: of the left ventricle the fascides presented much of their usual appearance; the transverse striæ were not so universally distinct as natural, but this might be due to the action of the spirit. Of the right ventricle, although many of the fascides presented a healthy aspect, the larger proportion of them had their fibrous tissue much confused, and presented little of the transverse striæ. There was an abundance of small globules, with very dark outline; they affected a linear arrangement, each series paralleled the other; but in parts they were irregular, and without any definite direction, more or less completely filling portions of the sheath; between them the tissue presented no marked character. There was a good deal of debris surrounding the specimens. This appearance was less apparent at the apex than at the body of the organ. On account of the uncertainty arising from the heart having been previously macerated for so long, and of the fascides preserving their healthy form and size, and of the absence of fat, I hesitate to draw any inference from these appearances. The difference between the

two ventricles was very decided, and the examination was made with great care. I should have added that acetic acid rendered the structure very transparent, but did not reveal any new element. Supposing the right ventricle to have degenerated, the attacks would be explained by the occasional failure of the right side of the heart, embarrassing the lungs by not sending the usual supply of blood, and at the same time producing congestion in the systemic veins; the state of the large arteries would explain the hypertrophy, and the hypertrophied ventricle explains the peculiar firm pulse. The very remarkable state of insanity at the close of the case, was probably, in part, due to exhaustion from want of rest, aided, perhaps, by the condition of the heart. It is curious, however, that it came on with its chief severity after rest had been given by opiates for some time; it began on the suspension of the opiates, and was relieved again by their readministration. The perfect removal of the distressing posture she was obliged to assume, and the inability to lie down towards the last is very remarkable; certainly it was not due to the resumption of the opiates; and the cause of the inability to assume the recumbent position for so long a time before her death, is itself not explained by the *post-mortem* appearances.

Correspondence.

ON THE RELATIVE VALUE OF MATERNAL AND FŒTAL LIFE.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—On reading your strictures on "Dr. Murphy's Lectures," and Mr. Edgar Sheppard's observations on *maternal and fetal* life, I do not observe much difference between you, as to the *acknowledged importance* of the former, when put into competition with the latter, since each of you allow, that when it is *clearly ascertained* that the sacrifice of one must be made to save the life of the other, that of the *mother must be preferred*. Who then "holds the scales?" Can any practitioner doubt—has any ever doubted, on this point of practice? I boldly answer—No! I have been in very extensive midwifery practice for five-and-forty years; I have never found in the practice of other medical men, who have consulted me in such cases, any hesitation or doubt on the subject, and decidedly never had any in my own.

But you, Sir, seem to infer that such sacrifices may be made hastily, and that by the admission of the mother's life being the most valuable, the comparatively less important one of the unborn fœtus may be mercifully sacrificed! *Credat Judex* No, Sir. I aver that this is a gratuitous assumption: the members of the profession practising midwifery, are too deeply interested, too feelingly alive, too morally inclined, too humanely attached to the infantine life, ever to permit on any occasion, the sacrifice of that life, where their strenuous and earnest endeavours can prevent it. They

do hold the scales, and I hope *pseudo-philanthropy* with them, will ever kick the beam.

You say, also, that it is *not right to destroy* the child, as soon as the mother's life is endangered, that the accoucheur is to *wait* till it really is, for the precarious chance of saving the child's life; and you justly say, "the law of God and man alike tells us, we shall not kill, and that a greater warrant is required, than the mere *accidental estimate* of the value of the life involved." Accidental estimate? No: sound logical deduction from well ascertained premises.

Wait not, when the mother's life is at all endangered, till you are satisfied that it will be sacrificed, before you rescue her by killing her child; if *you do*, and the mother dies, who then has disobeyed the law of God and man? To illustrate this, I report to you three cases that have very recently occurred to me in my practice here with my nephew, Mr. Robert N. Day, M.R.C.S., and L.A.C., at Harlow.

Mrs. H., aged 30, had been delivered of two children at the interval of a year between each, attended by two different gentlemen, and each time craniotomy had been performed, on account of the abnormal projection of the promontory of the sacrum; she was told by each medical attendant, that if she was ever again *enccinte*, it would be necessary, to insure her life, that her labour should be brought on at seven months. On being consulted, I obtained the particulars of her case from her former attendant, and agreed at the proper time to do the needful.

On the 19th of October last, I went with Mr. Day to her house, intending to dilate the os uteri with the compressed sponge tent and probe used for that purpose, but having easily found it over the pubes, I was able to dilate it with my finger, so as to admit the spring stilet, with which I punctured the membranes. In thirty-six hours labour began, but the os being rigid, I smeared it over with the extract of belladonna, mixed with lard, which had the desired effect of relaxing it in an hour, when I gave a dose of the essence of *secale cornutum*, and in another half hour the child was expelled and the case did well.

The second case occurred on the 21st of October last. Mr. Day sent for me to Mrs. B., aged 28, who had borne two children, she had been in labour twelve hours; the pains were severe but the head had not made any progress for more than six hours. There being much hæmorrhage I used the forceps at once, and speedily accomplished the delivery, saving both mother and child.

The third case was a very severe one. Mr. Day sent for me on the 6th of November instant, to a Mrs. C., aged 39, who had borne ten children, but had been injured in her back some eight months ago, and had not been able to move about during the last three months: she had been twenty-four hours in labour, and the head was firmly wedged at the brim of the pelvis, the last dorsal vertebra and the sacrum projecting so much, there was scarcely room for my two fingers to pass; after waiting some time, and the woman becoming much exhausted, I felt assured she would die, unless delivery was speedily accomplished. I failed in endeavouring to pass the vectis, and also the forceps from want of room, and the only alternative was craniotomy.

After using the perforator and passing the crotchet into the cranium, I was unable, though I had a firm hold, to move the head, and after breaking down the os frontis and parietalia, it required very considerable traction to bring it down, which was, however, safely accomplished, and the poor woman is doing well. I mention these cases, and I hope you will publish them, to show by the first that it is "*necessary in all cases,*" where the pelvis is so small as to cause *any danger* from delivery at the *full period*, to bring on premature labour at *seven months*, though you say not! By the second case, where there is danger to both mother and child by procrastination, to advise no time to be lost, but at once to save both by the early use of the forceps. By the third case, to *insist* upon the *fact* that it is *necessary to destroy the child* by craniotomy, to save the mother's life, and this is *not murder*, but if it is *not* done and the mother *dies in consequence*, if it is not murder, it is culpable homicide!

I am, Sir, yours truly,

WM. COLLYNS, M.R.C.S.

Harlow, Nov. 11, 1852.

THE AMENDED DRAFT BILL.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—The appearance of the "Amended Draft of the proposed Medical Bill" in the pages of the last number of the *Journal*, and your invitation for communications respecting it, reminds me of having hitherto neglected to direct your attention to a monstrous abuse peculiar to the medical profession, for which it does not, in my estimation, provide a sufficient remedy. I allude to the practice of charging high prices for medicines as a remuneration for professional services. Clause 23, indeed, empowers registered persons to recover reasonable charges for advice, visits, and medicines, and Clause 24 prohibits any other person from doing so; and this is all very proper and desirable, and would seem necessarily to lead to a discontinuance of the old system; but why leave to chance that which might so readily be reduced to certainty—why not *prohibit* a practice that is in every respect so objectionable? If medical men *will*, or *must*, supply medicines to their patients, being empowered by law to recover for professional services, it surely can be no hardship to require them to supply those medicines at the druggist's price; there need not be *two* prices for the same thing, and if the druggist's price is to be regarded as the fair market price, I would have such to be the only price recognized by law. And suppose it should result that medical men, when properly paid for their professional services as a separate item, should be able to supply medicines for *less* than the druggists' present charge, it may be no loss to the public to discover that their friends the druggists have hitherto made more free with their pockets than fair dealing could in all cases justify. There is no doubt that medicines may be supplied for less than the generality of chemists and druggists now charge for them, and that medical men may be able to supply them at a very low

price without any disadvantage to themselves, when properly paid for their professional services. I would not advocate the supply of medicines gratuitously, but in common honesty they should be supplied at a reasonable profit, and not as heretofore, at double, treble, five, or ten times as much as they are worth. A few additional words in Clause 23 would accomplish my purpose, and at once effectually annihilate one of the greatest evils the profession has hitherto had to deal with. You may possibly argue that the clause as it stands is calculated *ultimately* to do this. I admit that such ought to be its effect, but am unwilling that so important a result should be left to chance. Besides, there would be this advantage likely to arise from the prohibition—it would clearly demonstrate to the public the *necessity* for the change of system, and by placing our professional services in their proper and legitimate position, tend much to enhance the *status* of the profession in public estimation. And if it be objected that the profession will soon cease, after the passing of this Bill, to supply medicines to their patients altogether, I meet the objection by the assurance, that in small country towns and rural districts this will be found for the most part impracticable.

There is another point unprovided for in the Bill, and that is, quackery—quackery in the ranks of the profession: but Sir James Graham, who so unwisely distinguished himself as the patron of quacks and quackery, has, I suppose, rendered these gentry all but invulnerable; they must therefore of necessity, on the present occasion, go free, or be dealt with in a different way. It does, however, appear to be a good opportunity lost, not to invest the Medical Council of Clause 3 with *power* to decide what is legitimate in practice and what is not, and to punish those who are guilty of thus offending, by suspending their licence to practise, and by erasing their names from the registry. Such authority might, too, occasionally prove of great importance in the department of forensic medicine. I offer this latter suggestion, however, with considerable diffidence; and begging the Council of the Association to accept my thanks as one of the medical community for the pains they have taken to bring this long subject of agitation to a satisfactory conclusion, and with every desire to see the consummation of our wishes effected,

I am Sir, yours, &c.,

JAMES COLE.

Bewdley, Nov. 16, 1852.

THE CASE OF MR. COX.

To the Editor of the Provincial Medical and Surgical Journal.

SIR—My attention has been arrested by your report of the "Proceedings" of the "Bath and Bristol Branch" in relation to Mr. Cox, to whom, as well as the other gentlemen who spoke on the occasion, I am a stranger. "To err is human." It is admitted that a surgeon's claims for remuneration are, within reasonable limits, discretionary. A demand made under excitement caused by the misconduct of a patient for services meant at first to be gratuitous, is an offence so venal,

especially when acknowledged with regret, that if the Council wipe it from the tablet of their memory they will not damage "the honour of the Association" half so much as by persisting with affected liberality, but *severity* of intention, in an ill-sustained charge of fraud. The sentiments expressed by Dr. Symonds are entirely my own. Indeed, I may go farther: for though I am not disposed to extenuate the indiscretion of Mr. Cox, I deem him entitled to sympathy, since he has suffered from the groundless assertion that gonorrhoea and syphilis cannot coexist. Several times in my practice has this complication occurred. Last year a gentleman consulted me for a sharp attack of the former: the glans penis could not be fully exposed, chancres remained for some time undetected, and, in due course, secondary symptoms supervened. I doubt not that many of my professional brethren can adduce similar cases, and will acquit Mr. Cox of the graver portion of the charge. In relation to the rest, who shall cast the first stone at him?

I remain, Sir, your obedient Servant,
M.D., F.R.C.S.

SIR,—The Report of the Council will inform your readers that Mr. Cox has *withdrawn* from the Provincial Medical and Surgical Association. This step on his part, in the opinion of the Council, rendered further investigation unnecessary, and therefore we were not called upon to say anything on the subject.

In taking leave of this unpleasant affair, we beg to put before the profession the following statements, to the *truth* of which we pledge ourselves.

We went to the trial of Bourn *v.* Cox reluctant witnesses, without any previous communication with each other, or with the plaintiff, and without the slightest intimation as to what would be the nature of the questions proposed to us. We did *not* assert that syphilis and gonorrhoea could not possibly coexist. We *know* that the Jury were not influenced in their decision by any medical opinions about the coexistence of syphilis and gonorrhoea.

FREDERICK FIELD,
JOHN S. BARTRUM,
CHAS. ALEX. HARRIES,
EDWIN SKEATE,
EDMUND L. BAGSHAW.

Bath, Nov, 16, 1852.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In the report of the Meeting at Bristol in your last *Journal*, p. 589, I have just read with inexpressible surprise the following words of Mr. John Barrett:—"As to the operations, a young man whom he (Mr. Barrett) saw at the Court, named Biggs, he believed had stated that Bourn had admitted to him that the bougie had been passed." In answer to this I have only to declare *most positively and distinctly*, that Mr. John Barrett's statement has not the *slightest foundation in truth*, and is, indeed, exactly contrary to fact, as the only remark I made to Mr. B. was, "that having had a conversation with Bourn relative to his

disease, and *he having omitted all mention of the use of the bougie*, I believed (as I still do) that it had never been employed."

Leaving your readers to judge whether Mr. B.'s statement *could* have arisen from mistake, or whether it had any purpose in view, and relying on your well known impartiality to insert this letter in your next publication,

I remain, Sir, yours very obediently,
ROBERT BIGGS.

Charing Cross Hospital, Nov. 18, 1852.

AN URGENT CASE OF DISTRESS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Under the high sanction of the name of the Treasurer of your Medical Benevolent Fund, I venture earnestly to entreat permission, through the medium of your journal, to appeal to every lady, whose husband is a member of the Provincial Medical and Surgical Association, to co-operate with me in endeavouring to further the cause of benevolence on behalf of the unfortunate widow lady whose case was advertised in your last journal.

I am sure that the heart of every wife and mother must have responded to that touching appeal, and that each one has been ready to exclaim,—“What can I do?” I would humbly beg an indulgent ear to a suggestion which this feeling has prompted in my own mind,—that if each lady were to contribute twelve postage stamps, the sum, though small individually, yet collectively would form a considerable addition to the fund which is now being raised for the benefit of the poor widow and her destitute family, and we should each have the satisfaction of feeling, that by casting in our mite we had assisted towards relieving one of our afflicted sisters from that heavy weight of woe which, from my personal knowledge, is now crushing her to the earth.

The answers of those ladies who may kindly approve of my suggestion, will be most thankfully received by Mrs. D. POWIS, Cookham, Maidenhead; Mrs. T. B. WINTER, 28, Montpelier Road, Brighton; Mrs. NEWNHAM, Farnham, Surrey.

I am, Sir, your obedient servant,
CAROLINE NEWNHAM.

Farnham, November 12, 1852.

Foreign Department.

GERMANY.

THE CHEMICAL CONSTITUTION OF COD-LIVER OIL.

WINCKLER has published his investigations on this subject in a recent number of "*Buchner's Repertorium*." He has ascertained that cod-liver oil presents certain peculiarities of composition which distinguish it from any other fatty remedial agents. When saponified by *potash* it becomes disintegrated into cleic and margaric

acids and *oxide of propyle*; but when saponified by oxide of lead, it separates into the two aforesaid acids, and *propylic acid*; no glycerin (hydrated oxide of glycyle) being set free in either case. Hence, in cod-liver oil the *glycyle* is replaced by *propyle*, which consists of six atoms of carbon and seven of hydrogen. Hence cod-liver oil is the only official oil which can form *propylamine* with ammonia, and as ammonia is contained in certain of the animal juices, this compound is probably formed in them. Winckler has actually detected it both in the sweat and urine. [We may observe that Wertheim has ascertained that the brine in which herrings have been pickled contains very considerable quantities of propylamine; and that Dessaignes has found it in *chenopodium vulgare*—a plant which resembles pickled herrings in smell, and formerly was in great reputation for diseases of the female generative organs. Very probably this compound exists in the secretion of the vaginal mucous membrane.]—*Schmidt's Jahrbücher* Bd. 75, No. 2.

NEW PRESCRIPTIONS FROM THE PHARMACOPŒIA FENNICA—(Ed. 2nda, Helsingfors).

1. *Adeps Benzoinatus*.—Let one pound of prepared lard be melted with two drachms of gum benzoin, and the mixture be strained. The gum benzoin prevents the lard from becoming rancid.

2. *Emplastrum Ammoniac-scilliticum*.—Let forty parts of gum ammoniac be mixed with eight pints of vinegar of squills, and evaporated to the consistence of a plaster.

3. *Emplastrum Saponaceo-plumbicum*.—Let ten ounces of shavings of Castile soap be dissolved in forty-five ounces of olive oil; add nine ounces of white lead (the carbonate,) and a pound and a half of red lead (the red oxide); heat the mixture over a fire till it is perfectly dissolved, and assumes a brown colour; then add an ounce and a half of Venice turpentine.

4. *Emulsio Guaiaci, seu Mistura Antarthritica Bergeri*.—Let two drachms of powdered gum arabic, four drachms of guaiacum resin, and an ounce and a half of white sugar, be dissolved in nine ounces of peppermint water.

5. *Emulsio Salina*.—Let three drachms of tartrate of potash be dissolved in one pint of milk of almonds.

6. *Hydras Magnesicus in Aqua*.—Let three pounds of sulphate of magnesia be precipitated by a solution of potash, and sufficient water be added to the washed precipitate to increase its weight to seven pounds.

7. *Liquor Sulfatis Ferrici*.—Let eight ounces of sulphate of iron be mixed with an ounce and a half of sulphuric acid and eight ounces of water, and be oxidized with nitric acid; let water be then added till the mixture weighs two pounds. From two drachms of this *liquor*, three drachms of water, and seven drachms of the preceding *hydras magnesicus*, we may at once obtain the hydrated peroxide of iron used in cases of poisoning by arsenic.

8. *Syrupus Hydrargyri*.—Let one drachm of metallic mercury be triturated with three drachms of gum arabic, three of sugar, and two of rose-water,

till all metallic globules have disappeared, and then add four ounces of common sugar. Useful in the syphilis of children.

9. *Syrupus Oxycocci*.—Prepared from the fresh juice of the berries of *vaccinium oxycoccos*.—*Schmidt's Jahrb.*, Bd. 75, No. 2.

ON THE NERVES OF THE HEART.

Dr. Cloetta has carefully dissected the nerves in the human heart, and in the hearts of calves and oxen, and his results, in a great measure, confirm the statements of Dr. Robert Lee.

In the mammalia there lies between the pulmonary artery and the aorta a large nervous plexus, from which numerous branches pass to the auricles and ventricles, some running superficially, and others in comparatively thick cords entering the septum. On the auricles and on the auriculo-ventricular septa the nerves form plexuses, and ganglia are present. The superficial nerves may be very distinctly perceived in the hearts of oxen and calves, but are best seen in the heart of the foetal calf; they present little regularity either in their number or in their course. In the calf they form a distinct net-work; in man they are extremely difficult to demonstrate. In the ox and in the calf the superficial nerves present a number of flattened dilatations at the points where they traverse vessels; and these seem (according to Cloetta) to be the structures which Lee regards as ganglia; a microscopic examination shows, however, that they contain no ganglionic cells. The left ventricle is richer in nerves than the right; Cloetta was unable, from the want of any very good specimens, to determine whether in the human hypertrophied heart the nerves grow in the same ratio with the muscular substance. He could often perceive the nerves of the endocardium with the naked eye. He was unable to find the fascia cordis, which according to Lee, must be removed before the nerves are dissected.—*Cloetta in Verhandl. d. Med.-Phys. Ges. zu Würzburg*, vol. iii., No. 1.

ON OPIANINE, A NEW BASE IN OPIUM.

A Vienna apothecary was recently preparing morphia from a specimen of Egyptian opium; with the morphia which he obtained there was mixed another alkaloid, which he supposed to be narcotine, but which Dr. Hinterberger discovered to be a new base, and named *opianine*. It crystallizes in long, colourless, transparent, glistening needles. It contains sixty-six atoms of carbon, thirty-six of hydrogen, two of nitrogen, and twenty-one of oxygen. It is insoluble in water, and only very slightly soluble in boiling alcohol, from which it crystallizes on cooling. In its narcotic action it appears strongly to resemble morphia. A parallel experiment was tried with two kittens (each six months old). To one was given two grains of pure morphia, and to the other an equal quantity of opianine. In the course of eight minutes both kittens presented the following symptoms:—The pupils were very much dilated, the eyes were fixed, the tails were drawn

inwards, and there was foaming at the mouth; afterwards they walked unsteadily, trembled, and vomited, uttered occasional cries, and there was paralysis of the hind legs; they finally lay down, could no longer be roused, and were insensible to the action of caustic ammonia. In the course of a day they both recovered. —*Hinterberger, Sitz.-Bericht der Wien. Akad., der Wissensch. Bd. 7, No. 3.*

Provincial Medical & Surgical Journal.

WEDNESDAY, NOVEMBER 24, 1852.

It was our intention to have made some further comments upon the amended Draft Bill in the present number of the *Journal*, but we have been prevented doing so owing to the severe illness of the Secretary of the Committee (Mr. GEORGE HASTINGS) immediately on his return from Scotland. We may, however, state, that that gentleman, with Mr. NUNNELEY, has had several very satisfactory interviews with Deputations from the Scotch medical bodies, who have agreed to carry out the scheme by the framing of clauses on a similar principle to those already adopted by the Association for this country. We trust that the Deputation appointed to confer with the Council of the College of Surgeons in London, may be equally successful.

ALTHOUGH we have not received the official Report of the Council of the Bath and Bristol Branch of the Association, we understand that Mr. Cox has withdrawn from the Association, and has thus, of course, stopped all further investigation into his conduct. We have already expressed our sentiments upon this painful subject so fully, that there is no necessity to do more than express the hope, that by a rigid course of upright professional conduct, he may regain that *status* which he has now—we hope for a time only—lost. Whilst on this subject we beg to draw attention to the letter of Mr. COLE, published at page 622, which certainly, if attended to, would obviate much of the odium which the public now sprinkle upon us with no unsparing hand. If the profession could only agree upon a scale of charges suited to the varying aspects of medical life, this might—though not easily, be avoided.

OUR correspondent, Mr. COLLYNS, must pardon us for suggesting that his letter does not at all meet the point in dispute between Mr. SHEPPARD and ourselves. It is not that we differ as to the propriety of saving the mother's life, by the sacrifice of the child, but that we are not agreed as to the precise time at which interference is necessary. We fully agree as to the soundness of Mr. COLLYNS's practice, but in all of his cases everything was done to save the child which could be done, and therefore they are not in point. If Mr. COLLYNS, in his second case, had perforated the head, we should say that he would have acted most improperly; as it was, he did what all would advise, and saved both mother and child. The subject is worn threadbare, and we therefore refrain from any further observations upon it, especially as our space is limited by the necessity for accommodating our numerous correspondents before the removal of the *Journal* to London.

Medical Intelligence.

(From our own Correspondent.)

LONDON, Nov. 22, 1852.

I must mention the accident, which occurred at the Zoological Gardens through the folly of one of the keepers who, being intoxicated, began playing with the Indian Cobra di Capello. He was bitten by it on the nose, and dying about an hour afterwards, it has led to the deluging the daily press with letters laying down a plan of treatment to be adopted in such cases, in some of which the method pursued is rather sharply criticised, the writers not having taken into due consideration the state the man was in when he arrived at the hospital. From the account furnished in the columns of the *Medical Times*, it is evident that he was past all hope of recovery, the time having been allowed to elapse in the gardens, during which an attempt ought to have been made, without an endeavour to counteract the animal's poison. The proper plan, if the person is seen soon after the accident, is to cut out the bitten part if possible, to cauterise it, apply cupping glasses, or to suck it, as recommended by the coroner, as the poison may with safety be taken into the stomach; but if that be practised it behoves the operator to make sure that he has *neither cracks, fissures, nor broken surface on his lips*, for if he has, he will assuredly transfer the poison from the victim to himself. The application of *eau de luce* (an old preparation of ammonia and amber), with sal volatile, brandy, or other stimuli given internally, and keeping the person walking about, will generally prove successful; but if the time when this should be done is thrown away, and the patient is not seen till he is in the state that Gurling was, when admitted, then artificial respiration,

and the treatment used in the hospital, with perhaps the forming an atmosphere of ammonia around him, give the only chance for life, and a very poor one it is. Arsenic has been recommended as a curative agent, to be given in large doses; but its action on the system is much too slow to be effectual in cases where death follows in an hour or two. The celebrated Tanjore pill contains a notable quantity of that mineral. Sir E. Home mentions a case of a man bitten by a rattlesnake, who survived the injuries some fifteen or sixteen days, dying afterwards from the effects of diffuse inflammation in the part bitten. To cause a fatal result it is absolutely necessary that the poison be introduced into the blood; if applied to an unbroken surface, or taken into the stomach, it is effete.

An opinion has prevailed that serpents brought from a warm climate lose a great deal of the energy of their poison in the more temperate countries, but this and other cases prove that opinion to be erroneous.

Sad news have arrived from Germany. What Justus Liebig is to chemistry, was Nees von Esenbach to botany and natural history, and yet how different is their fate. The one, in the prime of life, courted by all men who love science, in the enjoyment of a high reputation, and of a lucrative professorship at Munich's famous University, and rich withal. The other, in almost extreme old age, deprived of his professorship for his political proceedings, without property of any kind, save his invaluable herbarium, and dying of starvation in a place no better than a cow-shed in the suburbs of Breslau. The following is the account given of the present condition of this Prince—*facile princeps*—in natural history:—

The *Wiener Zeitung* publishes an appeal on behalf of Nees von Esenbach, one of the most learned German naturalists, who, having lost his professorship on account of the part he took in the political troubles of 1848-49, is now living in the most extreme destitution and misery in Breslau. His deprivations are not comparative; he is literally threatened with death from old age and hunger. The paper states that the Professor, who is in his 76th year, lives in a low suburb of Breslau, in a miserable den that can hardly be called a room, over a cow-stall. His extensive library has been sold to pay his debts, and a large collection of plants, which in some branches is described as unequalled, he has in vain endeavoured to dispose of. It is his only property, and, after the trifle it may realize has been exhausted, there is nothing before the grey-haired *savant* but starvation.

But surely the literary and scientific world, albeit not itself rich, will never permit so sad a fate to overtake the rash politician, the learned, the talented *savant*? Is there no Mæcenas of the present day willing to part with a little of his wealth to rescue Von Esenbach from the horrors of death by starvation? The old man was not idle while his powers of mind could be fruitful. A more valuable or excellent work than his great one in folio, on botany, has never been presented to the world, and now is the time that his services could best be acknowledged. Poor Hancock, of Essequibo, himself an admirable botanist, and a clever and learned physician, after having been plundered by swindlers in

his old age of all he possessed, died sadly in this metropolis of disease, induced by poverty and want in its direst form. Let us not have to record the name of another great botanist as "starved to death!" If Germany will do nothing for one of her greatest sons, let England shame her by rendering efficient and timely aid. Such is our earnest hope and aspiration.

A strange affair took place a few days ago, near the Edgware Road, which has been recorded in the papers under the heading "Perils of a Surgeon." It might as well have been designated "Brutal Freaks of a Madman." A surgeon and his assistant, while engaged, by order of the Coroner, in making the *post-mortem* examination of a female suicide, was attacked by the husband, who, after seizing portions of the body, exhibited them to a mob he had collected outside the house, and after denouncing the medical men as his wife's murderer, called on those assembled to aid him in obtaining vengeance. He then rushed back to the room, tore the clothes from their backs, and made several violent attempts to cut their throats, in avoiding which the surgeon's hands were greatly mangled. The mob finally turned them out of the house. The sole remedy the medical men seem likely to get, is compensation for the destruction of their clothing, the husband being also bound over to keep the peace. Now, this is not enough; the medical men were engaged in the performance of a public duty, ordered by a competent authority, and are as much entitled to protection, while so occupied, as are the police. The fellow should have been taken before the Magistrates, by whom, doubtless, he would have been severely punished, if he were not sent for trial to the Central Criminal Court, for the attempt to commit murder. It was at the best a most gross case of assault. The victim was Mr. Obre, the criminal a carpenter, named Jones.

A singular ceremony took place a few days since at Islington. Mr. Nobbs, who for twenty-five years has been the surgeon, priest, and governor of Pitcairn's Island, in the Pacific, was admitted to holy orders by the Bishop of Sierra Leone, under letters dimissory from the Bishop of London. Pitcairn's Island, supposed to be the original of Byron's poem, "The Island," was first inhabited by the mutineers of the *Bounty* in 1789, and, after many scenes of horror and bloodshed, fell under the dominion of Adams, one of the mutineers, who ruled its population wisely, and well. Mr. Nobbs, who was acquainted with Adams, afterwards became their governor, their medical attendant, and, as already stated, their priest, marrying, baptising, and burying as such, although not ordained to the office. After having fulfilled these duties for a long period of time, he was sent by Rear-Admiral Moresley to Valparaiso, and has travelled thence to England for ordination. It is supposed that in a few weeks he will be received as a priest, and will then return to his happy, virtuous, and simple-hearted subjects. The whole affair, from the first setting sail of the *Bounty*, the brutal misconduct of Lieutenant Bligh to Christian and the others of his crew, the proceedings of the mutineers, the capture, shipwreck, and drowning of some of them, the punishment of others, and the

escape of a few with South Sea Islanders into the wide and wild expanse of the waters, the subsequent discovery of the survivors and their descendants on Pitcairn's Island, the bloody scenes there enacted, the subsequent penitence and beneficial rule of old Adams the mutineer, with the simple, affectionate, and earnest conduct of the inhabitants, and their submission to their pastor and surgeon, constitute one of those romantic chapters in history, which clearly prove that truth is indeed stranger than fiction. That a surgeon should have ruled sway for so long a time, is not so wondrous. Other examples might be adduced, and indeed the foundation of our Indian power is clearly referrible to the influence of an English surgeon over a native prince; but all the circumstances connected with the island are deeply tinged with romance, not the least of which is the filling of the patriarchal office, (for such it is in this instance,) by one who was to the inhabitants at once their ruler, surgeon, priest, and friend. Such a man does, indeed, set an example to the rulers of the earth, and at the same time, causes us to feel proud of our profession, and of his association with it.

During the last few years several inquests have been held on the bodies of persons deceased, who had been previously attended by homœopathic practitioners. In one instance, a married woman died from inflammation of the brain; the physician who attended her, formerly an allopathic lecturer, abstained totally from bleeding, and did not even give a dose of castor-oil, although the bowels were obstinately confined. We do not remember what verdict was recorded in that case, nor in that of a solicitor residing near Tottenham Court Road, who died from some chest affection, while under the care of a well-known homœopath. The principal feature in that case was the total and continued abstinence from food enforced by the disciple of Hahneman. In a third instance, a case of cholera near Camden Town, a similar abstinence, rigidly enforced by the homœopath, who, by-the-by, was the patient's brother, led the Jury, under the direction of Mr. Membury Wakley, the then Deputy-Coroner, to return a verdict of manslaughter, which, however, was set aside at the Central Criminal Court, if our memory mislead us not. Recently an inquest was held by the Coroner himself in Gloucester Place, Bedford Newtown, on the body of a female, 60 years of age, in consequence of a certificate of death as follows:—"Margaret Sedgwick died from inflammation of the lungs, peritoneum, and the liver; and her death resulted from, I believe, the neglect of the homœopathic attendant, and the general nullity of treatment." After hearing evidence, the Jury returned the following sensible verdict:—"Deceased died from inflammation of the lungs; but we are not competent to judge of the medical treatment." In all these cases the disease was acute, and of great severity; in all such cases homœopathy must fail; it is only when rest, a well-regulated diet, and the other means unconnected with real medical treatment, are sufficient for a cure or for relief, that "the general nullity of the treatment" can obtain a credit for usefulness to which it is not in reality entitled. In cases such as those we have mentioned, and in all of a similar nature, Hahneman himself would prove

utterly useless, unless he abandoned his absurd dogmata, and had recourse to the measures placed in our hands by the advance of science.

Disease appears to be extending amongst the products of vegetation. The potato plant and the vine have been for several years subject to a blight which has annually proved to be very destructive; during the present year, the vineyards have suffered more than on any previous occasion, even to their utter destruction in some places. The chesnut and walnut trees in many districts on the Continent have also been included in the visitation. The corn in Canada is the subject of an extensive blight; and here the onion and the apple have suffered. The latest intelligence we have, now represents the pear-tree as participating in this almost universal disease and destruction of vegetation. The malady has shown itself principally among the variety designated the winter pear, and known as the "green bury." Externally the rind is shrunken and depressed in many places; internally the fruit is full of brown spots, which soon cause rottenness. The appearance presented closely resembles that of a diseased potato; the malady is very destructive, and very rapid in its effects. The failure of the apple is very extensive; the crop, it is said, will not be equal to one half that of previous years. What can be the cause of all this, and where is it to end? Famine, and fever, the result of famine, must be the final result of such an extensive destruction of the means by which we live, and it is full time that the most careful and energetic investigations should be made to ascertain the causes of this blight, and also to find out the means by which its progress may be arrested, if within the power of man.

There is a report current that the homœopaths are about to obtain a triumph in Berlin: the celebrated university in that city, the diplomas of which have hitherto ranked among the highest in Germany, equalled perhaps only by those granted by the university of Munich, is, it is said, to be dishonoured by the establishment of a chair of homœopathic medicine. It is to be hoped that the other professors, at least all those connected with medicine, will show their indignation at the insult, by at once resigning their professorships, and that the falling off in the number of the students in medicine will show the authorities how injudicious such a step must be. They could hardly have adopted any other proceeding so likely to lower the value of their diplomas. After this the degree of M.D. (University Berlin) will be considered not only of no value, but absolutely a degradation. Meanwhile we have long had something of the same kind in the University of Edinburgh. When will that far-famed school of medicine be purged of its homœopathy? How, indeed, can the professors reconcile it to their consciences to be co-lecturers with a man, who must hold the opinion that the dogmata they teach are so erroneous, that if carried out they must tend to the destruction of life. And how can he retain his professorship, holding one doctrine and teaching another, or at all events, teaching those, who are imbibing from his colleagues doctrines essentially different and distinct from those he practises. They

are as opposed to each other as oil and vinegar, and cannot amalgamate. If these worthies must have an university and a school of medicine, they should have one of their own. At all events, while a homœopath retains a seat among the professors in the University of Edinburgh, and another is about to obtain a similar berth in the University of Berlin, the dogmata of homœopathy obtain a *quasi* legal status which they ought not to possess, and which the teachers and practitioners of legitimate medicine should exert themselves most strenuously to overthrow.

UNIVERSITY OF ST. ANDREWS.

List of gentlemen who had the degree of Doctor of Medicine conferred upon them, Oct. 22, 1852:— Thomas Allen, M.R.C.S., & L.A.C., London; Samuel Blackmore, M.R.C.S., & L.A.C., London; Leonard Buckell, M.R.C.S., & L.A.C., Chichester; Gustavus Matthews Burton, M.R.C.S., Lancashire; John Courtley, M.R.C.S., & L.A.C., Yorkshire; Maurice Davis, M.R.C.S., & L.A.C., King's Coll., London; Joseph Meldon Dempsey, L.A.C., London; James William Duffy, M.R.C.S., Chili, S. America; Charles Anthony Floyer, M.R.C.S., & L.A.C., Camberwell, Surrey; George Fayer, M.R.C.S., & L.A.C., Essex; Robert Anstruther Goodsir, Fifehire; Richard Hassall, M.R.C.S., & L.A.C., Ext. Lic. Coll. Phys., Surrey; Arthur Newstead Holmes, M.R.C.S., & L.A.C., Yorkshire; Frederick Lewins, M.R.C.S. Ed., Borvie, Kincardineshire; Frederick John Lowes, M.R.C.S., & L.A.C., Gosport; Francis Nottidge Macnamara, M.R.C.S., King's Coll., London; Albert Massey, M.R.C.S., & L.A.C., Camberwell, Surrey; William O'Connor, M.R.C.S., & L.A.C., London; Patrick Pantom, M.R.C.S., & Extr. Lic. Coll. Phys., Turriff, N. B.; John Dungate F. Parsons, M.R.C.S., & L.A.C., Gloucestershire; J. Henry Shorthouse, M.R.C.S., & L.A.C., Surrey; Charles Taylor, M.R.C.S., & L.A.C., Camberwell, Surrey; Charles Jean Tourrette, M.R.C.S., Mauritius; John Turnbull, M.R.C.S., East Lothian; Henry Watts, L.A.C., Staffordshire; William Wightman, M.R.C.S., & L.A.C.; Yorkshire; Simon Armstrong Willis, Lic. Fac. Phys. & Surg., Glasgow, Fermaugh, Ireland. Mr. Joseph Ewart, of Guy's Hospital, passed the requisite examinations, but in consequence of an informality in his certificates, his degree was temporarily deferred.

UNIVERSITY OF LONDON.

M.B. SECOND EXAMINATION, 1852.

First Division.—Thomas Bridgwater, King's College; Thomas Armstrong Cammack, University College; Thomas King Hornidge, St. George's Hospital; Robt. Coane Roberts Jordan, King's College; Joseph Lister, B.A., University College; Thomas Littleton, University College; Frederick William Pavy, Guy's Hospital; Thomas Morley Rooke, G. y's Hospital; John Henry Trouncer, University College.

Second Division.—William Thomas Gaye, University College; Henry Parfitt, King's College; Bernard Rice,

St. Bartholomew's Hospital; Elias Jones Roberts, Richmond Hospital, Dublin.

In accordance with the recent regulation of the Senate, that the examinations shall be conducted "by demonstration from preparations, and by requiring the candidates to report on cases of actual patients,"—

The examiners in physiology required the candidates to name and describe microscopic specimens, illustrating important points in physiological anatomy.

In Surgery, the candidates were examined by demonstrations from dry and wet preparations, illustrative of various surgical diseases and accidents, and of their treatment.

The examiners in Medicine required the candidates to examine patients in the wards of a metropolitan hospital, and afterwards to report in writing on the cases, and also to examine microscopically various specimens of morbid products.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted members on Friday, November 5th:—Jean Valleton de Boissiere, Trinidad; George Bulleid, Oakhampton, Devon; James Ekin, London; George Richmond Ferris, London; Christian August Flemmer, Horsor, Denmark; Thomas Foster, Newcastle-upon-Tyne; Henry James Franks, Whittlesey, Isle of Ely; George Britton Halford, London; Benjamin Kerr, Cowes, Isle of Wight; George Kirkhouse, Merthyr Tydvil; William Knox, Castle Combe, Wilts; Angus Macmillan, Hull; Harry May, Burslem, Staffordshire; John Ray Philip, Canada; William Renwick, Boulogne-sur-Mer; William Saville, Wakefield, Yorkshire; George Spicer, Hammersmith; Sanderson William Mathew Walker, St. Michael's, Azores.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, November 4th:—William Edward Musson, Birkholme, Lincolnshire; George Richard Pratt Walker, Kent.

Gentlemen admitted on Thursday, Nov. 11th:—Henry Lane, Stratford-on-Avon; John Turle, Richmond Villa, Holloway.

OBITUARY.

November 11th, at Bedford, Daniel Bull, Esq., M.R.C.S., and formerly of Cranfield, in the same county. His sufferings were most protracted and extreme, but his end was peaceful. This case excited a great amount of sympathy last year through the medium of the medical journals.

TO CORRESPONDENTS.

As we already have more communications in hand than we shall be able to insert, we must beg our correspondents to forward them in future to DR. CORMACK, unless they require immediate attention.

Communications have been received from Dr. R. Hall, An O. d. Subscriber, Dr. Meret, Dr. H. Johnson, Dr. E. Copeman, Mr. Nunneley.

URGENT CASE OF DISTRESS.

THE Widow of a Medical Man, late of Norfolk, was left with Six Children, in great distress, by the death of her husband three years since, after a protracted period of ill-health, from disease of the heart, which incapacitated him from the active duties of his profession, as well as prevented his making a provision for his Family by Life Assurance; since that time the Widow has been struggling to maintain herself and Family by her own efforts, aided by the kindness of near friends, and is at this moment engaged in fitting herself for a National Schoolmistress, at the Cheltenham Training School; but having exhausted all her resources with failing health and increasing difficulties, she is compelled to make this **APPEAL** to a generous Public, who have always been disposed to listen to the cry of the Widow and the Orphan, and to whom she looks with confidence in the hour of her entire destitution. The case will be vouched for, and any inquiries answered by the Rev. Francis Close, Cheltenham; Rev. Wm. Browne, Aldeby, Beccles; the Rev. — Bromby, Principal of the Training School, Cheltenham; and the Rev. L. P. Hill, Westminster. Subscriptions most thankfully received by Herries, Farquhar, and Co., St. James's Street; T. Hatchard, Esq., 187, Piccadilly; John Churchill, Esq., 46, Princes Street, Soho; Dr. Bernard, M.D., and C. T. Cooke, Esq., Cheltenham; Frederick Rose, Esq., Mattishall, near Dereham; W. Newnham, Esq., Farnham; and the other Gentlemen who have kindly undertaken to answer inquiries.

Subscriptions already received.

TO SURGEONS, DISPENSING CHEMISTS, &c.

SULPHATE OF QUININE, PURE CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of Herring Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is Chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of Commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but **ITS PURITY AND GREAT REDUCTION IN PRICE** are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, as also of the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capsuled with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom; and in quantities of not less than 100 ounces of JACOB HULLE, Jun., Proprietor, Chemical Works, TRINITY STREET, SOUTHWARK, LONDON.

Oct 23, 1852.

NEW WEEKLY SERIES OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

TO COMMENCE JANUARY, 1853.

OFFICE, 37, GREAT QUEEN STREET, LINCOLN'S INN FIELDS,
LONDON.

It is intended that the "JOURNAL," while it retains its Original Character as the ORGAN OF THE ASSOCIATION, should secure, at the lowest possible expense, all those advantages which a Weekly Periodical is capable of affording, and that it should present a faithful Digest of Medical Literature and Science, as well as an attractive Summary of Professional News.

The CONTENTS of each Number will be usually classed under the following Principal Divisions:—

- I. LEADING ARTICLES.
- II. ORIGINAL COMMUNICATIONS.
- III. BIBLIOGRAPHICAL NOTICES.
- IV. PERISCOPIC REVIEW.
- V. REPORTS OF SOCIETIES.
- VI. ASSOCIATION NEWS.
- VII. TOPICS OF THE DAY.
- VIII. OBITUARY.
- IX. APPOINTMENTS.
- X. THE EDITOR'S LETTER BOX.
- XI. ADVERTISEMENTS.

The OFFICE will, on and after the 15th of DECEMBER, be open every day, Sundays excepted, from NINE A.M., to SEVEN P.M., for the transaction of the Commercial Business connected with the "JOURNAL;" and (when not unavoidably prevented by other duties) the EDITOR will attend at the Office, and receive MEMBERS, every WEDNESDAY, from FOUR to a QUARTER-PAST FIVE, P.M.

MR. CHURCHILL'S NEW PUBLICATIONS.

A SYSTEM OF PRACTICAL SURGERY. With Numerous Illustrations on Wood. By WM. FERGUSSON, F.R.S. Third Edition. Foolscap 8vo, cloth, 12s. 6d.

DR. FOWNES'S MANUAL OF CHEMISTRY. Edited by H. BENICE JONES, M.D., F.R.S., and A. W. HOFFMAN, Ph.D., F.R.S. Fourth Edition. Foolscap 8vo, cloth, 12s. 6d.

A HAND-BOOK OF MEDICAL CHEMISTRY. With Illustrations on Wood. By JOHN E. BOWMAN, Professor of Practical Chemistry in King's College, London. Second Edition. Foolscap 8vo, cloth, 6s. 6d.

PULMONARY CONSUMPTION AND ITS TREATMENT. By WILLOUGHBY MARSHALL BURSLEM, M.D., Senior-Physician to the Blenheim Dispensary. Post 8vo, cloth, 5s.

ON THE CONTAMINATION OF WATER BY THE POISON OF LEAD; and its Effects on the Human Body. By JAMES B. HARRISON, M.R.C.S. Second Edition. Foolscap 8vo, cloth, 3s. 6d.

ON RHEUMATISM, RHEUMATIC GOUT, and SCIATICA; their Pathology, Symptoms, and Treatment. By HENRY W. FULLER, M.D., Cantab., Assistant-Physician to St. George's Hospital. 8vo, cloth, 12s. 6d.

ON CONSUMPTION; ITS NATURE, SYMPTOMS, AND TREATMENT. Being the Essay to which was awarded the Fothergillian Gold Medal of the Medical Society of London. By RICHARD PAYNE COTTON, M.D., Assistant-Physician to the Hospital for Consumption and Diseases of the Chest, Brompton. 8vo, cloth, 8s.

LECTURES ON THE DISEASES OF CHILDREN,

DELIVERED IN THE

Chatham Street School of Medicine, Manchester.

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Vienna, etc.

LECTURE XVI.

Treatment of febrile rheumatism in its various forms.

General remarks regarding the first and principal febrile symptoms. Rheumatism of the head may be rheumatism or inflammatory rheumatism. Indications regarding the head:—leeches, cold fomentations, a full dose of calomel, dry covering, mustard poultices, blisters; effects of, and difficulty with, opium; rheumatism of the stomach; absolute abstinence from medicine necessary. Indications in acute stages of rheumatism:—leeches, warm narcotic fomentations, and mild evacuating injections; in smaller degrees, small opiate injections. The precautions necessary. Obscure symptoms of rheumatism of the stomach, which is easily aggravated by medicine. Rheumatism of the intestines and liver, the most frequent amongst rheumatic local affections in childhood; its general characters—of pain and stools. Expectant conduct, if diarrhoea supervenes upon a recent fever. Alleviating qualities of the bilious kind. Symptomatological comparison between simple bilious diarrhoea and that which arises from rheumatism of the liver; different and opposite treatment of both. In simple bilious diarrhoea, no opium, no direct checking, but emetics or castor oil. In children in these cases, ipecacuanha is in general to be preferred to tartarized antimony, with the exception of the acutest articular form. Occasional combination of the acute bilious dyscrasy with rheumatic fever; treatment. Rheumatic bilious diarrhoea—characters and treatment;—the inflammatory form—characters and treatment. Character and changes in the fever connected with the sero-bilious form—issues, complications. The whitish serous diarrhoea—symptoms and dangerous character; death from it; analogy with cholera; pathological uncertainty. Treatment:—minute doses of calomel; energetic external means. Brownish, and other dirty-looking serous stools. The yellow diarrhoea. Catarrhal diarrhoea; its connexion with rheumatism. Peritoneal rheumatism. Recapitulation and general principles of the treatment of febrile rheumatic diarrhoea. Few internal remedies; faults in practice in this respect. Imperfection of our knowledge of diarrhoea of children, and their importance.

GENTLEMEN,—In the treatment of rheumatic fever and local affections connected therewith, I beg to remind you first of those general directions exposed in former lectures, concerning any fever in its commencement before a special character has come forth. Heat and pulse, head and abdomen, attract our attention first in many instances, as in other fevers. You ought not to be too active at the onset, but wait twelve or twenty-

four hours before you take a decided step; even then it will require close and clever examination—in the well-known manner—to unravel, in the speechless child, how far the head-symptoms may be attributed to fever itself, how far to gastric disorder, or to local rheumatism.

Rheumatism of the head, as you know, may be rheumatism, or may take on the inflammatory character. Let me now suppose there are evident symptoms of pain in the head, that you have found out the painful spot, and that the plaintive moaning and drooping down of the head have not diminished, although the bowels have been freely moved. If these be the symptoms during the first day or two, whilst fever runs high, or increases, then prudence commands you to apply leeches and cold fomentations afterwards. Besides, you may order one full dose of calomel, and not many small ones. If the fever and heaviness of the head be less, the signs of rheumatism, on the contrary, severe and evident, then you will do better by applying a mustard poultice to the neck, and then covering the head, or its affected side, with a large piece of thin oiled silk. Thus local perspiration, and by it relief, may be effected, whilst cold fomentations might have increased the pain.

Opium is exceedingly beneficial in the latter instances, only that the diagnosis must come to a decided result before you could use this powerful remedy. Lively expression of pain, with restlessness, total absence of soporose oppression, are sufficient reasons to recognise the fever as rheumatic; these are essential conditions for its use. I have been blamed, in a German periodical, some years ago, for this, as they said, hazardous practice—opium, in a head affection of a child. I think, myself, it is difficult for the young practitioner to take, with security, so important a therapeutic step; but had I now, as I had at that time, a choice of cases before me in a hospital, and skilful sub-physicians to watch carefully the symptoms, I would not hesitate to show you, occasionally, a case, which I might regard as mere rheumatism of the head, in spite of the fever, and the beneficial effects of opium therein; the fever, of course, must not be too high, and the doses only moderate, or small ones. I prescribe Dover's powder in this case, from a quarter to one grain, to children from six months to two or three years' old.

If, by the means indicated, sufficient improvement is not effected on the second or third day, the most promising remedy will always be, a large blister on the neck, as soon as the degree of fever is no longer too high for its use. The state of the abdomen claims not less consideration than the head. Besides the management of the stomach and bowels, by an emetic or purgative, indicated in the case of bilious or gastric derangement in any kind of fever, and already pointed out in previous lectures, there is in the rheumatic sometimes an encouraging or even urgent indication for some strong remedies—like quinine and opium—which, in order to produce the intended good effect, require a healthy condition of the stomach.

Rheumatism of the stomach, if ascertained by the signs indicated in my last lecture, excludes every medi-

cine, be it intended for the stomach itself, or to act, through it, upon some other part.

As to treatment of the rheumatic stomach itself, there is nothing more essential than to abstain from medicine. One single drop, or grain—unless it be of a homœopathic or imaginary kind—will be sufficient to increase the disturbance. The irritability and intolerance of the rheumatic stomach in children exceeds all belief. I have seen two drops of aqua laurocerasi excite sickness; and a few teaspoonfuls of cold water will occasionally have the same effect.

Let us suppose the child to have been affected for only one day with frequent vomiting, tense, tender, and hot epigastrium, in connexion with high fever,—let the child be so much affected that it cannot hold up its head; it moans heavily, with shut, or half-shut eyes; the pulse is about 150 to 170; costiveness, not relieved by castor oil injections. In this case, be it gastritis, or merely rheumatism threatening with it, you must apply leeches, then warm fomentations of a poppy-head decoction, and injections of *small quantities* of warm rice-water, every four hours, with some fresh almond oil. In the absence of those (apparently, at least,) inflammatory symptoms, but with signs of severe pain present, I adopt a different treatment; I recommend a small injection of warm water, with two teaspoonfuls or more of table oil, and half that quantity of sugar; not to be pushed too far up into the rectum, whilst the stomach is to be kept under hot fomentations of the above narcotic properties. When the injection comes away, then it will be seen whether a second of the kind be advisable. Thus, after a sufficient evacuation of intestinal secretions had been effected, I order an injection of one or two ounces of warm rice-water, with a proportionately full dose of tincture of opium, to be repeated after a few hours, if required, or sooner, if a part of it comes away, valuing in this case the quantity which might have remained in the bowels. Do not neglect the importance, in every case, of opiate-injections, if you wish to get an efficient effect without dangerous narcotism. These measures may be repeatedly assisted by one or two leeches; and if all be without effect, as soon as the degree of fever allows it, a blister must be applied—the sovereign local remedy of every form of rheumatism.

According to my experience, acute rheumatism of the stomach, not a frequent affection of children, very seldom takes the real inflammatory character; it generally remains within the limits of rheumatic irritation or rheumatism, and in the majority of cases I saw, was connected with intestinal rheumatism, or that of the liver.

The seat of the affection may be in the muscular or serous coat, or in both together; it seems impossible to establish in the living child a pathological and diagnostic distinction between both. The mucous membrane is consensually irritated, and thrown into functional disorder. In inflammatory degrees, of course, it must share, more or less, in this process too.

In some instances the affection in a child affords very obscure symptoms; we observe no salient pain, no

tenseness of the epigastrium, only the patient is exceedingly restless, thirsty, with occasional appearance of, or continued sickness, and vomiting every small quantity of milk, water, or medicine, which it swallows. There we have to choose (according to appearance) between the emetic or the total abstinence from medicine, and great suffering and mischief ensues, if unhappily you fall into the error of administering the former when the latter is required. I can assure you, however, I have seen in these instances, great inconvenience also from what may be called bland medicine. In rheumatic irritability, as well as in the nervous affection of the stomach, there is no kind of internal medicine which is bland—everything is irritating. A practitioner who is not aware of this, changes his prescription, and changes again, under the continuous increase of uneasiness, sickness, and exhaustion of the patient.

Intestinal rheumatism is, on the average, a little less painful, and more manageable, as far as regards our treatment of it by the mouth and stomach, but still the sufferings of the child are occasionally very great; sometimes it is connected with consensual irritation of the stomach. There is always some expression of uneasiness or pain referrible to the belly, which generally appears bloated, or tense, but from time to time the child bursts into loud painful moaning or crying, under which he draws up, and stretches, his legs alternately, or if not too much depressed by the fever, turns from one side to the other, all signs indicating a more salient attack of pain, and this lasts generally until a strepitous discharge of serosity follows, and appeases the little sufferer for some time, but not so completely as in cases of flatulent or spasmodic pain. The presence and character of fever, besides, assists us in settling the diagnosis. Vomiting is also an occasional symptom, be it from consensual or material disturbance of the stomach. Intestinal rheumatism, with diarrhoea, is a frequent, perhaps the most frequent, form of rheumatism in the early period of life. The seat of irritation, of which diarrhoea is the consequence, may be either in the serous or muscular coat, or in both together, and in acute cases partake more or less of the inflammatory character. In the great majority of cases of rheumatic diarrhoea in this sense, the emitted serosity is thin, mixed with more or less of mucus and bile, and of either a yellowish, whitish, or greenish appearance, according to the predominance of either of those elements.

There is nothing more essential in children's practice, particularly with patients of tender age, than to be for a time inactive observers in recent cases of fever, followed by diarrhoea. In many cases that sudden outbreak of diarrhoea, with or without sickness, will decrease and cease by itself in a day or two. In many instances it will prove beneficial, diminishing fever or pain, when it must not be checked, though the attack is likely to produce an alarming appearance of pallor and languor in the countenance; but you must consider and value not only one or two symptoms, but the whole in their relation.

The alleviating quality of diarrhoea in fevers of every kind, is frequently exhibited by stools containing an

abundance of bile, and my remarks on this—thus far, refer to the rheumatic as well as to any other form of fever. But there may be a great proportion of bile both in the motions produced by rheumatic irritation, when it extended from the intestines to the liver, and in those which are simply bilious. To discern both of these conditions is of great importance. In the former case it would be a fault to attempt checking it by different means, in the latter, not only this, but if not an emetic, at least a dose or two of castor oil may be required. And again, in what we may call the rheumatic-bilious diarrhoea any purgative is improper, and the emetic generally causes a most vehement irritation with pain, hyperemesis and overpurging.

Those who are accustomed or careful to look at these matters more minutely than it was the custom heretofore will at once perceive the importance of the point in question. How to value and manage diarrhoea which supervened upon, or commenced along with, rheumatic fever, in a tender and speechless child, is indeed a question both extensive and difficult enough to realize. I may begin, however, with a few practical hints, in addition to what I said on intestinal rheumatism in the last lecture.

On the average, in bilious diarrhoea of rheumatic origin, the child shows more expressive signs of pain, than in the simple bilious form, (see Lecture XIII., and the belly is more puffed up around the navel and downwards, be it rheumatism of the intestines, peritoneum, or liver. In the latter case, their seat of pain being in the serous envelope, as soon as we exert pressure over the right hypochondrium, the abdominal muscles contract and prevent pressure of our fingers upon the liver, which, if we attempt to do, causes the child at once signal pain. In the bilious state there may be pain, but this is not so severe; there may be fulness or tension of the right hypochondrium, but it is not so great; there may be also a quantity of serum mixed with the bilious discharges, but it is much less than in the rheumatic. Besides these manifestations, I may add, if the character of diarrhoea is so decidedly and strongly bilious as to require instead of checking, an emetic or castor oil, at this stage of it, the fever will be less remittent, and the child, on being lifted up, manifests more decided signs of a heavy head or even oppressive drowsiness. The bilious diarrhoea, if unconnected with rheumatism of the liver, but arising from a certain chemical change in the blood, frequently met with in acute fevers, particularly in summer time, presents neither so much pain as to call for the use of opiates, nor so much loss of liquids as to justify the idea of directly checking it. It supervenes occasionally upon the rheumatic fever, in its more acute degrees, with severe local affections, just as it does in ague, pneumonia, measles, or scarlet fever, commonly within the first two days, when we frequently see after its appearance, a diminution of the leading symptoms; and in this case we neither leave it to itself, or promote gently the evacuation of bile by castor oil; or, if the head of the child appears oppressed, and we find the region of the liver uncommonly full, but no pain under

pressure, we prescribe an emetic. I take it for granted in recommending this, that there is no sign of abdominal rheumatism present, because this would entirely forbid the use of an emetic. In general I may say, if in the course of rheumatic fever in a child, with however slight indication of abdominal pain, an emetic seems to be required, prudence commands us to use ipecacuanha in lieu of tartarized antimony, with the only exception of the acute articular form, by which, besides the joints, also the heart is threatened, and in the first stage of which the more decided effect of tartarized antimony may be desirable. In some instances, (rare in young children, during the hot part of summer or autumn, as we had it here in Manchester this year—1852,) the acute bilious dyscrasy of the blood (over carbonisation) complicates rheumatic fever, and may also cause bilious vomiting or diarrhoea. In this case the treatment must be modified, more or less, according to the principles expressed in Lecture XIII.

But there is a rheumatic-bilious diarrhoea different from the former, when rheumatism of the intestines acts upon the liver, or rheumatism has even its seat in the liver, and thus the secretion of bile becomes increased. It consists of a greenish serosity, but not so dark a green as the former. Pain and other symptoms proper to this state I have already mentioned. There may be evacuated a great quantity of serum by frequent stools, but if the marking green colour and a certain density of the liquid show a great amount of bile, and at the same time a high degree of heat of the skin and heaviness of the head are present, in this case, in spite of the rheumatic character of the diarrhoea, of the severity of pain, and loss of liquids, opium, in whatever form, and however mildly acting, is counter-indicated, and other means must be resorted to, which are the following:—According to the degree and character of the pain and fever, leeches, and afterwards warm poultices must be applied; internally, simply tepid rice-water. No opium, no calomel.

The less we find to be the proportion of bile to that of serosity, and the more the degree of pain to that of the fever and the heaviness of the head, the more the case approaches that kind of rheumatic diarrhoea, in which opium becomes indicated, and in which sinapisms or blisters have an excellent effect. But it will be in its place to call more especially your attention to the

Inflammatory rheumatic diarrhoea, or, in other words, to that form of diarrhoea which is the effect and sign of inflammatory abdominal rheumatism, which we may regard as the first degree of serous enteritis. This character of rheumatic diarrhoea will appear, if it has to come, within the first few days of an acute febrile onset of abdominal rheumatism; tension, and pain, will be so severe as to depress considerably the power of the child. There will be great tension and heat of the belly without remission, the child will lie rather quietly on his back, emit most painful sounds and cry, though sometimes languidly, under our pressing on the belly. In this form, vomiting is also one of the most obvious forms and the stomach may be more or less affected in it, along with the small intestines. Acute rheumatism

may pass into acute enteritis, in which the quantity of serosity becomes less and less, but still continues thin, of a greenish brown or reddish brown colour. Vomiting of muco-bilious liquids frequently takes place, with evidently painful exertions of the child. On close inspection by the eye or microscope, we find in the majority, blood mixed with the sero-bilious or sero-mucous liquid. The seat of this form appears to be most frequently in the lower half of the intestinal tube, in a more or less extensive tract of the serous and muscular coat. In higher degrees, the inflammatory process very soon spreads to the mucous membrane, which, in addition to the serosity, causes the excretion of thick mucous or croupous pieces, with or without spots of blood, in general under severe tenesmus. In fact, tenesmus is infinitely a more characteristic symptom proper to the irritation or inflammation of the mucous than of the serous membrane. But this belongs, not to the present purpose. I wished only to mention the first step of inflammation, when arising from acute rheumatism. The treatment is obvious:—leeches, in sufficient number, and warm linseed poultices; to appease the thirst, and at the same time the best internal remedy, is thin tepid rice-water, and similar injections, but only small, pushed up slowly in a gentle manner, and to be repeated according to their effects twice, thrice, or four times a day. All these are little things, but of consequence in children's practice. They must not be too thick nor too much in quantity at once, in order to avoid the evaculatory movements of the intestines. Besides this, from a scruple to a drachm of the strong mercurial ointment may be rubbed in on the belly at once, but not to be repeated (if repetition should be required) before the third day. If the stomach of the child presents no trace of irritation, we may assist this treatment by from $\frac{1}{12}$ to $\frac{1}{16}$ of a grain of calomel every four hours (for the age from six months to two or three years), with only from two to four grains of sugar, to each dose; and if there be no counter-indication, (*i. e.*, no signs of extensive biliosity, and the head not too much oppressed) from $\frac{1}{12}$ to $\frac{1}{4}$ of a grain of Dover's powder. The complication of gastric rheumatism, however, excludes the use of both.

As to the fever connected with the mentioned varieties of sero-bilious diarrhoea. It may be in some cases very high in the commencement, but unless the intestinal rheumatism passes into enteritis, it soon becomes remittent, and in ratio to the quantity of emitted liquid, the temperature of the skin abates, but the frequency of the pulse increases more or less.

The inflammation from rheumatic diarrhoea is not so frequent in infants and children as the former described, and less so its transition into decided enteritis, although in febrile cases, as soon as intestinal pain becomes salient, leeches are the favourite remedy. But they are more so, I am sure, than required.

The transition into chronic intestinal rheumatism, is not a frequent issue of this form. According to what I have seen, children seldom die from the sero-bilious diarrhoea, except when the rheumatism gives rise to in-

flammation, of which we find well known traces in the dead body. In some cases the emitted liquids assume other colours and properties, of which I will speak by-and-by.

The complication of peritoneal rheumatism with all the various forms of the intestinal and sero-bilious diarrhoea, is an occasional occurrence. I will mention in its place some particulars concerning it. Rheumatism of the stomach is rarely connected with it. We know already the symptoms. Now, I will draw your attention to another acute form of diarrhoea. The less the proportion of bile in the evacuation, the more they assume a whitish colour, and in some cases they are quite white, with a variable quantity of spurious mucosity.

The *whitish rheumatic* diarrhoea presents, of course, like the other, the general characters of rheumatic pain, of sudden and strepitous evacuations, after which the pain becomes less. It is generally very abundant, and differs, according to my experience, from the bilious or sero-bilious, in as far as under the influence of these, in many instances, we perceive a diminution of the fever; this is not the case with the whitish serosity, it lessens the heat of the skin, but without lessening or even augmenting the frequency of the pulse; more than any other it has an evident exhausting effect. It contains occasionally, a striking quantity of albumen. Fainting and vomiting sometimes precede the motions, without local affections of the stomach. It has nothing of the bilious, and not a decided inflammatory character. In fact the pain is on the average more remittent than in the sero-bilious kind, and the languor, in proportion, is more alarming. In some cases pain is excessively severe, I have not been able to come to a satisfactory conclusion on its nature, but assuredly many a child dies from it. I have seen it in Manchester the same as elsewhere. Sometimes after having been profuse it lessens, but the skin and pulse at once show that it is exhaustion of the vital power which causes its decrease or collapse.

This is the only form of febrile rheumatism which, under my own observation, has caused death in a direct way, and without complication. And I have seen, on *post-mortem* inspection in cases where death has occurred in consequence of this, all very young children, where the intestines were white and anæmic, but the liver and spleen tinged with dark venous blood; and like what I have observed in some instances of cholera in children, great quantities of rice-water-like liquids have been evacuated.

The years 1844 and 1845 were the most fruitful in rheumatism at Pesth, and (as I mentioned in my Hungarian work,) hundreds of cases of acute rheumatism were entered at that time in our case-book, amongst which were many with the diarrhoea in question. Simultaneously I have seen many cases also of summer cholera in children, but there was no Asiatic cholera in the country at the time. The fact is, that whilst many of the above-mentioned cases, from the form of fever and character of the pains, were evidently rheumatic, others—partly by the simultaneous serous vomiting, low tem-

perature, piercing cries, and such movements as though they suffered from spasms in the legs—approached more or less completely the form of cholera.

The question arises,—Are such cases rheumatism of the spinal cord? I dare not answer. The fact is, that in many of these cases the belly, between one evacuation and another, resists moderate pressure; and blisters on the belly prove little efficacious. In some fatal cases of acute whitish diarrhoea, with high fever in the commencement, a slower course of exhaustion took place—a transition into what I called (in the 13th and 14th Lectures,) the secondary asthenic stage of fever, but with a longer course—above a week, or even two or three; and in these we find here and there, besides various accidental complications, congestions, or partial inflammations of the serous or mucous coats, follicular erosions and swelling of the mesenteric glands, but nothing characteristic of the rheumatic origin and nature of the disease, nor of any other.

As soon as I perceive abundant whitish motions, in a menacing degree, no fever deters me from applying a large mustard poultice on the belly, and after its removal then to the back, about the dorsal part of the spine. The condition of the skin in this form of fever even requires its being irritated, the more so in proportion to its lower temperature. On both legs I order hot linseed poultices, with or without the addition of $\frac{1}{8}$ to $\frac{1}{12}$ part of mustard powder, to promote energetically active perspiration, after the manner of the French physicians. Internally, every three hours, from $\frac{1}{6}$ to $\frac{1}{12}$ of a grain of calomel, and if there be salient pain and the head not too heavy, or oppressed, from $\frac{1}{12}$ to $\frac{1}{4}$ of a grain of Dover's powder, each dose of it. If the stools become more and more greenish, this I generally found to be a good sign, but alone it is seldom enough, if at the same time we do not succeed in procuring perspiration. The affected children are very thirsty, and they want liquid food. Besides the milk of the breast, of which not too much ought to be given at once, or in elder ones only, a very thin tepid decoction of rice, is the best beverage for these cases.

To promote perspiration by internal remedies, can only be attempted within the first day or two. Dover's powders must at once be left off as soon as we see the belly become more tense and the child restless, throwing its head and hand from one spot to the other. Amongst the sudorifics (besides Dover's powder) I can only recommend a light infusion of lime-tree flowers. There is often an excessive intolerance of both the stomach and the blood-vessels for every medicine. This we must have regard to more than ever in these cases of children's practice, and be studious at the same time to supply by external means.

I beg to remind you of what I said of sponging in the asthenic stage (Lecture XIII.) Besides that, I have to remark, that in cases of the well-characterized rice-water diarrhoea, approaching cholera in its appearance, I have had some good results from energetical blistering along the spine, and rubbing vigorously the whole anterior surface of the body with a mixture of three

parts of water and one of diluted hydrochloric acid, until the skin becomes reddened; after which the child must be covered well over, and the mentioned sudorific leg poultices, and similar means upon the belly, may be applied, to draw away the morbid irritation from within, and promote a beneficial cutaneous crisis.

The complication of peritoneal rheumatism I did not notice with this form. In the majority of cases the tension and pain under pressure of the belly, are less than in the sero-bilious diarrhoea. The belly may even be soft for a while after the evacuation; but this does not exclude severe attacks of pain.

In general these are severe and serious instances of practice. The day before we saw the child restless, the pulse about 150 to 160, the skin hot, each discharge preceded by vehement expression of pain, whitish, but with a green or yellow hue; now it lies quietly on its back, the pulse 180 or more, the temperature lower, the countenance pale and sunken, the oculozygomatic imprinted, and the eyes dull-looking, as if it were affection of the brain; the expression of pain before the motions becomes less, but languid moaning more continuous, accompanied by occasional languid movements of the head and limbs; the quality of the stools changes; it is now of uncoloured serosity, or brownish and exceedingly offensive; the belly less tense than at the commencement. The child presents an alarming aspect. The parents are ready to try everything; but very few remedies can be even tried without damage; though the majority of practitioners yield but too easily to the temptation of multiplied applications. *Complications* seldom do occur in this form.

Under whatever circumstances, and upon whatever ground, profuse white serous diarrhoea may depend, it increases continually the over-carbonization of blood, and not seldom beyond the control of science.

Injections themselves, such as are intended to appease, are frequently but an irritating agency; and internal remedies of any kind may augment the disturbance. I have seen but few children recover from this state; and even in these it was more by external than internal treatment. Minute doses of calomel, if they effect no favourable change within a day or two, their continuance is but a nuisance.

As to the rheumatic character of the form in question, though in the beginning it may have been clearly expressed by the mentioned form and type of fever and abdominal pains, if the serous diarrhoea be profuse, even articular rheumatism or swelling, when present at first, will soon vanish.

The bilio-serous diarrhoea is by far more manageable than this, and has in many instances even a beneficial effect upon the rheumatic fever; when it becomes dangerous, in general it is when it assumes, more or less, the whitish aspect, or some other troublesome colour.

The *brownish serous diarrhoea*, dirty-looking, and of an intense ammoniacal smell, or other badly-coloured liquids, do not commonly appear with the onset of rheumatic fever in children, but rather make their appearance during its course.

Yellow diarrhoea, *i. e.*, more abundant serosity mixed with the usual excrements of infants, though occasionally connected with febrile abdominal rheumatism, is in general not serious, and more manageable than any other. If too abundant, say five or six times a day, and assuming more the sero-mucous or sero-bilious aspect, it may be checked, more or less gradually, according to the degree of fever or rheumatism connected with it, by warm poultices, or sinapisms and Dover's powder. The decoction of *jalep*, more active than warm rice-water, and a real benefit in the obvious catarrhal diarrhoea of children, is little efficacious in the greenish or whitish forms, but will be found useful in the yellow.

Catarrhal diarrhoea, a discharge of almost pure mucosity, more or less united with the yellowish elements, does not frequently complicate intestinal rheumatism, except when this passes into inflammation, when the serum becomes less, and thick mucus appears in the stools, with more or less simple catarrhal diarrhoea, and is by far less connected with pain than the sero-bilious.

Peritoneal rheumatism, of which I forgot to make mention in the last lecture, in its fixed form has about the same objective symptoms in a child as intestinal rheumatism; it acts also upon the intestinal secretion, and produces sero-bilious diarrhoea. I have not been able to discover any other diagnostical distinctions than this. In fixed peritoneal rheumatism the tension of the belly is more conspicuous and continued, and pressure by far less tolerated. Intestinal rheumatism may occasionally be connected with it; but it seems to me impossible to point out diagnostical signs for this case; nor is there great practical interest in the distinction. The treatment is entirely the same as that which I mentioned for the sero-bilious diarrhoea.

A moderate degree of peritoneal rheumatism is scarcely distinguishable from the intestinal; the inflammatory, on the contrary, is more easily recognized, by the more palpable degree of tension, superficial tenderness, and heat. The treatment is obvious:—leeches, the strong mercurial ointment, poultices, minute doses of calomel, and moderate ones of Dover's powders, form the whole therapeutical measures.

I will now briefly recapitulate the treatment of recent acute and febrile abdominal rheumatism connected herewith. First, in mild cases, the internal treatment ought to be either omitted or confined to some moderate doses of Dover's powder, with jalap, and hot poultices on the belly.

The management of the bilious, sero-bilious, or white (in connexion with fever), has been minutely indicated. I cannot repress the repeated caution against the use of many remedies, almost promiscuously and at random applied in diarrhoea of children.

In any kind of febrile rheumatic diarrhoea, I know only of two *directly* useful substances—opium and calomel. The latter being useful in the serous diarrhoea, with *retention* of the bilious elements, *i. e.*, in the whitish serous evacuations, is not available in the opposite condition,—in serosity overcharged with bile.

And in this point the superficiality with calomel is obvious. It is indicated in every form, the most opposite. It is the most flexible remedy. Sir Astley Cooper, whose memory stands high in my estimation, used to say of it, it “regulates” the abdominal secretions and functions. In the present day, I believe, such ideas and expressions are too vague, and in opposition to the consciousness of our *non scire*, and the established spirit of modern inquiry, as to be admissible any more.

The emetic and castor-oil act indirectly, but in appropriate cases (biliosity) efficaciously, against the diarrhoea. I have mentioned their indications, as well as of leeches, poultices, and other external means.

Great mischief, of every day's occurrence in children's practice, is done, in rheumatic diarrhoea, by a number of other remedies. If opium does not soothe, then follows the chalk mixture, or even calumbo, with or without magnesia, and the like. Some of these remedies may be useful in some stages of the catarrhal diarrhoea, but none of them is good in the forms in question. A great principle it is when we treat intestinal rheumatism by opiates to act, at the same time, by every possible means upon the skin.

There are cases not uncommonly met with which improve merely by external treatment after all internal attempts have failed, or been injurious. In spite of the difficulties in diarrhoea of children, by close investigation it is possible to find out the real indications. Biliosity, active or passive congestion in the liver, irritation of its serous coat, and serous mucous inflammations, are the most obvious conditions, and most important to be found out.

I feel the great imperfection of what I have exposed, or attempted to illustrate to-day. I have been severed too soon from a fertile field for inquiry. I shall receive, however, with thanks, every correction of my views. Diarrhoea of children in general is not treated of as it ought to be in works however valuable; and in practice treated superficially. This, nobody will deny: therefore I thought I ought to devote proportionally more time and care to this than to other subjects minutely and laudably exposed in contemporary works. I have—unitedly with my distinguished subordinates—in the Children's Hospital of Pesth, paid great attention to the *clinical* observation of diarrhoea in children, but how far have we been from a satisfactory degree of knowledge of so obvious a derangement, and so dangerous in infancy; I should feel happy, therefore, if my observations answered the mere purpose of giving an impulse here and there to further *practical* inquiry in that direction. Certainly the treatment of diarrhoea in children is of great consequence to human life and professional honour. Next, on some special relations between acute rheumatic fever and diarrhoea in the tender age.

CASES OF
HEPATITIS, DYSENTERY, AND DIARRHŒA,
WITH REMARKS.

By W. T. BLACK,

ASSISTANT-SURGEON TO THE FORCES, SOUTH AFRICA.

CASE I.

THE case of hepatitis occurred in a female, Mrs. M., of a plethoric habit of body, who had been subject to similar attacks while resident in India. The first symptoms inducing a call for medical aid, appeared on June the 11th, 1852, and were of a decided character. They reached their intensity on the 14th, notwithstanding the remedies used; the urine was scanty, thick, bilious coloured; fever high; breathing oppressed; and considerable pain in right hypochondrium. A smart dose of jalep and calomel was then given, which gave much relief, and sweating now took place, which considerably lessened the fever, and may have been caused by the depressing effect of the purgative allowing the diaphoretics previously administered to act easier upon the skin. The purge was repeated the next day, and gave further relief to the local symptoms, and the sweating still continued to keep down the fever. The mouth now showed the effects of mercury, an ointment containing which had been used to dress a blister applied to the side. The intense symptoms now abated, and gradually declined under the use of saline drinks and purgative pills, but the stomach could not bear antimonial medicines since the aggravation of the disease on the 14th, and the patient continued to feel much weakness. From some cause a relapse of the complaint began on the 25th, and the next day had reached as great intensity as ever, with the addition of dyspnoea, and sense of oppression and weight around the the region of the liver; and the bowels became again costive and the perspiration ceased. A large dose of compound jalap powder gave relief to the local symptoms, its action being kept up by a purgative and saline mixture, and perspiration again appeared to subdue the fever. No attempt was made to affect the system with mercury this time, as its action did not even prevent the relapse. The bowels were now kept freely open by colocynth and calomel pills at night, and salines during the day, and as the morbid action seemed to subside, so these means were gradually reduced in strength, and though much constitutional anxiety continued, yet by the middle of July she was quite convalescent. No tonics were given and no addition of stimulating regimen, merely attention being given to keeping the bowels regularly open, so as to allow of nature effecting a healthy reduction of the vascularity of the liver, and a restoration of its normal secretion.

CASE II.

The case of bilious diarrhoea occurred in a bastard man, (Privulf), of strong and healthy appearance, and the first symptoms of engorgement of the liver and

portal system showed itself by complaint of great pain in the loins and side, which were relieved by a Dover's powder at night, and a dose of salts next morning, which caused the evacuation of a large quantity of bile by stool. On the 7th of July they appeared again under the form of nausea, pain and soreness of the belly, loss of appetite and a very white coated tongue. After the exhibition of an emetic, the evacuation of bile manifested itself, and bilious diarrhoea supervened, and continued more or less for several days, sometimes with increase of pain, generally spasmodic, but always attended with soreness of belly. Compound chalk powder and opium pills at night gave most relief. The diarrhoea gradually declined, and the patient by the 10th, was convalescent.

CASE III.

Heathfield's case showed a combination of dysentery and biliousness, the engorged portal circulation seeking relief by either one mode or the other, according to circumstances. He had been five or six days ill before applying for medical aid. The symptoms were dysenteric, with a very white coated tongue, thirst, nausea, &c. June 27th and 28th he had given him two doses of rhubarb, calomel, and nitrate of potass, which relieved the abdominal symptoms very much, and operated gently, no more blood being passed. An attack of abdominal pain occurred next night, which was relieved by opium. On the 30th the bowels were natural, but nausea was complained of, with loss of appetite continuing, and white tongue, the first and last symptom obtaining alleviation from sedleitz powders. On July 2nd, as debility and anorexia seemed now the leading symptoms, decoction of cinchona was ordered, under which he improved, but it caused costiveness and flatulence, which rhubarb and soda relieved. He became convalescent by the 5th of July.

CASE IV.

Almost similar symptoms attended Mrs. W's. case, but rather less intense, and more chronic, which first came under notice June 19th. Biliousness had been present some days, with abdominal pain and white tongue. Colocynth and calomel pills were first given, and then salts, but on the 22nd dysenteric purging appeared with increase of abdominal pain. Pills of calomel and opium were given, without any effect in checking the sanguineous purging, but the tongue was now cleaner, and compound chalk powder was tried instead, and with success. On the 24th the stomach became disordered and bilious, and the tongue white, which a dose of rhubarb and soda mitigated, but did not open the bowels, which was required to be effected with the administration of rhubarb and calomel. As there still seemed a tendency to dysenteric purging when the bowels were moved but likening mucus instead of blood, compound chalk mixture was again given. Powders of small doses of calomel, opium, ipecacuanha, and gum, were next given, to act as an alterative and restore a proper state of the intestinal secretions and

their evacuations, which succeeded. On July 11th a relapse of dysenteric symptoms appeared with abdominal pain, which was relieved by opium pills, followed next morning by a dose of rhubarb and calomel; and on the 13th, as biliousness of the stomach again appeared, a dose of rhubarb and soda was given to relieve it, and convalescence seemed to be established. Subsequently the mouth became sore, and on the 17th of July a severe attack of pain in the belly, with shivering and fever supervened, with costiveness, which was subdued by pediluvium fomentation, followed next day by doses of sedlitz powders, which operated freely, and relief to all the symptoms took place. Soreness of the mouth, and a continued tendency to salivation, however, manifested itself, otherwise the patient is convalescent.

CASE V.

Pure dysentery marked the next case, in Mr. S., who reported himself sick June 23rd, though he had been suffering for a week previous. The symptoms were sanguineous purging, with its accompaniments, and attended by few constitutional symptoms, except loss of appetite. A powder of rhubarb and calomel was given, and relieved for a time all the symptoms, and as he considered himself able to undertake duty he was not put under any medical restraint. Up to the 6th of July he had four of these doses, but the bloody motions generally returned with straining, a day or two after the taking a powder, but the accessory symptoms had now subsided, the appetite had returned, and the tongue became clean. He was now kept to his room, and pills of calomel and opium regularly administered according to the recurrence of bloody stools, which were finally checked and then allowed to become natural, and by the 15th he was convalescent. No affection of the mouth took place. The compound calomel powder so useful in the former case, was tried in this before the pills, but found ineffectual, and the latter were beneficial here, but inoperative in Mr. W's case.

CASE VI.

The last case was a decided one of dysentery, and occurred in an European named Jennings, a groom, who had been ill with it occasionally for a month before, and had usually found relief from doses of rhubarb and calomel, but did not attend regularly. On the 7th of July the symptoms were so intense, that he was taken into hospital. Pills of calomel and opium, beneficial in the last case, were here of no avail, and seemed to increase the symptoms. Opium in pill was tried, to relieve the abdominal pain, but without success; also compound chalk powder, but with no better effect. Two grains of calomel and one grain of opium, in powder, were now given every four hours, and relief at the end of twenty-four hours was experienced. There was no fever and the tongue was not very much coated, and half the above dose was tried, with some cinchona added, but the symptoms again returned as bad as ever. The full dose was again put in requisition every six

hours, with good effect, and after twenty-four hours lessened one quarter, without allowing any return of the severe dysenteric symptoms. On the 12th a blister to the abdomen removed all pain, and an injection of warm water was administered that night, with further relief. There was now mercurial foetor of the breath, approaching to salivation, but no affection of the gums. On the 13th, as I considered the amendment produced was not commensurate with the large and repeated doses of calomel, an alteration in the treatment was ventured upon. A large dose of Dover's powder, a pediluvium, and other accessory means were enforced, to produce profuse perspiration that night, and followed next morning by a purgative dose of rhubarb and soda. On the 14th, great relief was experienced and the balance of the circulation and distribution of nervous fluid seemed to have become more naturally established, the stools were now changed and took on the form of diarrhœa. Small doses of Dover's powder and hydrarg. were given night and morning, with the best effect, and compound chalk powder, should diarrhœa be troublesome, in the intervals. The stools became gradually more natural, more fecal and bilious, and the appetite much improved, and on the 20th of July he was convalescent.

Remarks.—All these six cases will be seen to have occurred in the course of one month, leading to the supposition that similar exciting causes for the diseases were present in each case, or that a single endemic cause prevailed, as they all happened in the same locality at Shiloh. The diseases all implicated the same system of organs—two being developed at one extremity of the intestinal tube, another at the other, three being intermediate. In the case of hepatitis, the hyperæmia of the liver was immediately relieved by strong purgatives, diminishing thereby the fluid contents of the portal system. The hyperæmia of the general circulation or fever, was relieved by the production of profuse sweating. The calibres of the vessels, both local and general, were thus allowed an opportunity to exercise their natural resiliency, and return to a natural size. The pressure on the secreting cells of the liver by the enlarged blood-vessels, is coincident with arrest and nonelimination of secretion, which takes place easier when that was removed. The same would occur in the general circulation. As heat is commensurate with an increase of fibrin in the blood, so is there an increase of fibrin in inflammation and fever. Fibrin is also considered as an excrementitious form of albumen, so that the object of medicine would be to endeavour to get this superabundance eliminated from the system. Its retention in the circulation leads to its deposit in organs predisposed, and in some cases with an impediment to their functions. This elimination of the fibrin can be accomplished by increasing the secretory powers of the different organs. As during inflammation little or no secretion is formed, so the biliary matter, not being liberated from the blood, would accumulate in the circulation, its more essential organic constituents would remain unformed, or in the state of fibrin, and the

colouring matter would appear to tinge the countenance, and flow off by the urine.

That the inflammation of the serous surface ever takes place, independent of any diseased action in the substance of the liver in ordinary cases of so-called hepatitis, would, I think, admit of a doubt. Pneumonia may exist independent of pleurisy, though hepatitis and congestion of the liver could not exist long without involving the serous covering, because morbid effusions have easier egress into the vacant air-cells of the former. Mercury seemed to have no ultimately beneficial effect, as a relapse of the complaint occurred after the affection of the mouth by the mineral, and during its continuance. The same effect towards the relief of the disease was induced in the relapse by medicines containing none of that ingredient, and the cure was permanent, without the mouth being again affected. On theoretical grounds, even mercury would be inconsistent with subduing increased action of the liver, unless on the principle of *similia similibus curantur*. Antimony during the height of the disease proved hostile to the stomach, causing vomiting when given either in the fluid or solid form to induce diaphoresis.

In the bilious diarrhoea most probably there exists hyperæmia of the portal circulation, the vessels of the liver not being in a diseased state at all, and therefore do not give way to dilatation; and this is rendered probable, from the paucity of bile existing in the latent state. The treatment of bilious diarrhoea under the above supposition, must evidently be palliative; the hyperæmia has found a vent, and ought not to be unduly checked. The increased quantity of bile flowing off ought to be shielded from injuring the coats of the intestines in its passage through them. Symptoms will announce if it produces morbid effects on the mucous membranes, by the occurrence of soreness if the mucous membrane has been bared of epithelium, and of pain when the exposed subjacent tissue of muscular fibre is thrown into unnatural spasm. Remedies appropriate to these conditions would require to be exhibited to afford relief, as anodynes to diminish sensibility, and to allay the susceptibility of the nervous fibrillæ. Any matter, as peculiar aliments, tending to increase the contents of the portal blood, should, of course, be avoided, such as admit of absorption by the lacteals being preferable to such as enter the veins. The allaying of the force of the disease would be safer than checking quickly its symptoms. An overloaded portal circulation may also cause its hyperæmia to relieve itself indirectly by the effusion of its overloaded contents from the thinner mucous membranes, as from the colon, producing a form of dysentery. The more depending and enlarged portion of its circulation would suffer first, as in the rectum and sigmoid flexure. The circulation in the colon may be presumed at all times less active than that of the small intestines, as it takes less share in digestion and absorption of aliment; it could not, therefore, relieve itself so easily as the upper parts, from having less activity—local activity of circulation having little to do with the force of the heart.

Want of this property, it is well known, also in a morbid sense, leads to congestion. The epithelial lining of the colon is less liable naturally to change than that of the stomach and small intestines. Should a course of diet, as an animal one, be in use, still less would the shedding and reproduction of epithelium exist, than in cases where a vegetable diet was usual. The chief current, and the strongest of the portal circulation, must be in the afferent and efferent vessels of the stomach and small intestines, that of the colon being tributary to, and more sluggish than, this great stream. Should the portal circulation become hyperæmiated, then would this congestion of the colic vessels be increased, and give a tendency to effusion. This morbid event might be either sudden, when a strong external cause was applied, or gradual, and only show itself when the pressure of the blood had reached a maximum, which would be indicated by such a symptom as a sense of expression in the abdomen. The gradual loss of blood would thus tend to prevent the accession of fever, which would have greater cause to arise when the disease was brought on suddenly before the engorged portal blood had found any relief by effusion. Inflammation would, in a sudden case, be more likely to arise also from the same cause, and be followed sooner and easier by destruction of parts, and arrest of the natural functions, which would be less likely to take place so rapidly, or to that extent and intensity, in a protracted case. Effusion of blood in these cases acts as a naturally local abstraction of blood. When the symptoms have once commenced, the nervous action of the intestinal canal is thrown out of its balance, and becomes concentrated on the diseased part, hence irregularity of peristaltic action, and want of action in the small intestines evidenced in the absence of fecal evacuation, and these of a vitiated character. As the portal circulation has now got a vent for its contents, less bile is formed, which would also arise from the loss of harmony in the action of the abdominal sympathetic nervous power. Hence medicines having the power to increase the bile, would divert the morbid effusion of portal blood, and such as tend to allay spasm would allow of the restoration of the nervous balance. Medicines also which increased the secretions and peristaltic motion of the small intestines, would be beneficial on both suppositions; but such as would increase the bile, and act like the latter, would be supposed to afford greater relief to the overburdened portal circulation, and transfer the normal current of blood, as it exists naturally in a greater amount to the small intestines.

As amylaceous articles of diet seem to be more fitted for nutriment in these cases than animal or albuminous vegetable substances, one may conjecture their peculiar fitness arises from their assimilation requiring a greater activity in the secretory powers of all the salivary system of glands than in those of the liver; and besides, from their absorption in the shape of sugar, not adding to the increase of the fibrinous elements of the portal blood.

Mercury in some form seems to exert a curative effect in dysentery, some constitutions bearing calomel, some

agreeing with hydrargyrum cum creta, &c., better. This effect does not appear to be in every case coincident with the establishment of an affection of the entire system, as evidenced in the gums, though witnessed apparently in one of the above cases. In Mr. S. no constitutional affection from the mineral supervened. The influence must then have been entirely confined to the abdominal organs concerned, and could not have passed through the liver; or, if so, must have returned with the bile, upon which secretion perhaps, after all, the necessary effect has to be produced. In other cases I have witnessed the same, and besides, have seen the mouth affected, and still the progress and violence of the disease not checked materially. The case of Mr. S. got well by checking the complaint, that of another by the supervention of a diarrhœa, either from the transference of increased action to the small intestines, or the transmutation of the dysenteric morbid processes in the colon into those of the saline affection. The occurrence of perspiration in Jennings's case was the turn of the disease, the balance of the circulation and nervous fluid seemed to be restored by it at a critical period, so that the organs essential to a restoration of health had become supplied again with a due share of each, the complaint was thus robbed of its means for carrying on the war, and health had an opportunity of resuming its empire. Whether had the affection of the system with the mercury conducted also to this end? That the mineral in the form of calomel had entered the blood, seemed to be established by increase of the saliva, and mercurial fœtor of the breath, yet the dysenteric symptoms did not very materially change for the better. I am inclined, on the whole, to consider from these cases, and from others previously under treatment, that its curative effect is local, and confined to the organs concerned in the disease in the abdomen. It may be sedative, as when calomel is combined with opium, as in Mr. S.'s case, it is slightly stimulating to the biliary and intestinal secretions, so as to restore the balance of the portal circulation. In the case of Mrs. W. and Heathfield, checking the dysenteric symptoms by simple opium, seemed to occasion biliousness of stomach, inferring that the portal blood desired to relieve itself by that channel instead, and when medicines were given to correct the latter symptoms, they did not appear to bring a return of the dysenteric symptoms. Calomel and opium in Mr. S.'s case evidently acted accumulatively, and together with rest, allowed a natural redistribution of the portal circulation and nervous fluid. The difference of the effect produced by different medicines, in these cases, seemed to have no clearer cause than constitutional peculiarity, and the cause of the difference in treatment arose from the difference in circumstances at the time, and the necessity of counteracting symptoms as they arose. The benefit subsequently shown, must have been derived in these cases of dysentery, from the previous exhibition of purgative doses of rhubarb and calomel, which took off the oppression of the portal circulation by increasing the flow of bile, thus relieving it of its load, and in an early case no doubt would be sufficient to afford nature

an opportunity to restore a healthy state of the economy of the large intestines. The diarrhœa produced in Jennings's case, was apparently of yellow bile, such being the colour of the motions, and this seems generally the colour which the subsequent diarrhœa, under the influence of mercurials, takes on. What difference, then, chemically speaking, exists between yellow and dark-coloured bile? Secretion of dark bile, I fancy, is produced in cases of hepatitis, by purgative doses of mercurials. About the same time as these cases above narrated took place, shewing hyperæmia of the portal circulation, other slight ones happened in other people, as biliousness of stomach, where colocynth and blue pill or calomel, followed by sedlitz or salts, effected cures. The causes of this general indisposition it would be almost futile to endeavour to enter upon; it might be put down to increased diet of meat from scarcity of vegetables at this time of the year; it might be from cold, but that would be just as liable to affect any other system of organs, without a predisposition. Heat is out of the question: so is moisture, as the season is otherwise distinguished, being very dry.

The diet is more vegetable in this country in summer and autumn than in winter and spring, though abdominal complaints prevail more in the latter period than in the former, while in England the prevalence occurs in the autumn, when there is more vegetable food. In this country exclusive animal diet is supposed to be the internal cause of these complaints; in England, a superabundance of vegetable food.

An increased vegetable diet would tend to increase the secretory powers of the intestinal canal, and this carried to excess would lead to such an amount as easily turn into inflammation under proper exciting causes, and the disease would be active. The warmth and dryness of the air here would keep up perspiration in ordinary times, while the coolness and moisture of that of Britain would tend to check and cause revulsion of the general fluids to the mucous membranes generally of the body. A diminished vegetable diet or a correspondingly increased animal one, would demand less than ordinary powers from the mucous membranes, as animal and albuminous vegetable food likewise, becomes easily absorbed direct from the stomach, except fat. The intestines, especially the large ones, would have less call upon them to furnish secretion, and the previous afflux of blood to which they had been accustomed in the summer and autumn, would have no vent on the mucous membrane, the volume of the portal circulation being still maintained. The same under the use of an albuminous diet. The portal blood would thus go to the liver, not much changed, as organic changes take place in it for the production of secretion, and would therefore be of a different constitution than otherwise, and there would also be less call for biliary secretions; so from want of local organic activity the portal circulation would become surcharged with unchanged venous blood, less adapted, at the same time, for the purposes of the liver. Its effusion through the thin membranes of the colon, nature may take as one way of relieving itself, and hence the dysentery be induced. In the

former state of disease the hyperæmia would be active, and probably more arterial, here congestive and venous, as the nature of the evacuated blood demonstrates.

As in the pure cases of dysentery, the overcharged portal circulation finds relief by the direct effusion of its contents, and that taking place at a limited and specified extent of the intestinal canal, so engorgement of the liver and vessels of the upper primæ viæ would occur, less than where this direct uncomplicated effusion did not take place, as in the intermediate cases of Privulf, Heathfield, and Mrs. W. In these the congestion of the portal vessels seemed more general, as there was evidently a tendency to disorder of the upper primæ as well as the lower bowels. The implication of the former being further shown by the earlier and deeper white coating imparted to the tongue, irrespective of the symptoms. The tongue, in this pure dysentery, does not seem to become affected till later in the disease, continuing tolerably clean at the commencement, and then results from the effects of local inflammation taking place in the colon, and the subsequent disorder of the whole primæ viæ. This condition of the tongue in the former cases may be conjectured to result from an arrest of the shedding and reproduction of the epithelial lining of its mucous membrane, an event common to it, and that of the stomach, &c. The old epithelium remains attached, none being fresh formed underneath, which would also occur amongst the numerous mucous glands of similar localities, hence checked secretion and congestive states of the capillaries of the mucous membranes are coincident. The removal of such a state of matters would be the restoration of secretion and of the current of blood to a healthy activity.

ON SAVINE.

By EDWARD COPEMAN, M.D.

PHYSICIAN TO THE NORWICH HOSPITAL.

Read at the August meeting of the Norwich Pathological Society.

THE late trial of Mr. Pascoe, a member of the medical profession, for the crime of procuring abortion, excited, as you all know, considerable interest, and, for a time, no little sympathy, on the part of his professional brethren. It has been since but too surely proved that, whatever might at first have been the opinion as to the justice of the sentence, his crime was of a deep dye, and deserved the punishment awarded. But the medical evidence on which he seemed to have been condemned is still open to criticism, and it is with the belief that practical good may result from a consideration of the principal point involved in it,—namely, the propriety, or otherwise, of employing savine as a legitimate medicinal agent, that I now venture to occupy a few minutes of your time with the subject. I do not remember the exact statements made at the trial by the medical witness; but the purport of his evidence was to impress upon the Jury that savine was now never given by medical practitioners for truly

medical purposes; that it was a dangerous medicine; and that, when used, it was in all probability employed with some sinister intent. It, therefore, becomes a proper medico-legal question whether or not savine can and ought to be employed as a medical agent; for the evidence I have referred to was listened to by the Judge, and probably believed by most of those who heard it; and it is important that no wrong impression on the matter should rest on the minds of Judges and Juries in future investigations of the kind.

Savine is an evergreen shrub, belonging to the natural family *conifera*; and its active qualities appear to reside chiefly in an essential oil of much the same constitution as oil of turpentine. All authorities represent it as a drug possessing considerable power upon the uterine organs; but some describe it as an exceedingly useful and efficient emmenagogue, whilst others speak of it as a dangerous and poisonous medicine. "Savine and its essential oil are emmenagogues; the fresh plant is too frequently employed by the peasantry as an abortifacient, but cannot be employed for this purpose without seriously endangering the life of the mother." (Phillip's Translation, Pharm. Lond., 1851.)—"It is, perhaps, the most powerful uterine stimulant of the materia medica, and is occasionally administered in amenorrhœa, though always requiring the utmost caution, lest it induce inflammatory action." (Brande's Manual of Pharmacy.)—"Savine is a powerful stimulant to the uterine organs, and is employed as an emmenagogue with much benefit in amenorrhœa and chlorosis depending on torpor or deficient action of the uterine system. In consequence, however, of its poisonous properties it should be used with caution; its employment is contraindicated where there is the least tendency to irritation or inflammation of the uterus or any of the pelvic viscera." (Nelson on Medicines.)—Nevin and Pereira recommend it as the most effective of all emmenagogues. I will not, however, occupy your time by further quotations, but proceed to the relation of my own recent experience of the drug.

CASE I.

Amelia Woods, about 18 years of age, was admitted as an out-patient at the hospital on the 4th of October, 1851, for chlorosis and amenorrhœa; of a pallid unhealthy complexion, weak circulation, and inclined to be fat. I ordered her a course of steel; but as her attendance was irregular, and she seemed to derive no benefit from the treatment, I admitted her into the house on the 13th of December, and gave her for a time steel and aloetic medicines. These failing, on the 20th of January, 1852, I ordered a mixture composed of Ol. Sabinæ, gtt. iv.; Mucil. Acac., oz. j.; Mist. Camph., oz. iij.; a fourth part twice a day. On the 24th six drops of the oil were put into the mixture; on the 25th, eight; and on the 30th, ten; which dose—namely, five drops daily—she continued to take until the 4th of February, on which day menstruation commenced and lasted four days, in natural quantity. No uncomfortable effect from the medicine was ever com-

plained of. She was discharged *cured*, and has remained well up to the present time.

CASE II.

Ann Ragg, a stout, plethoric-looking woman, of, I believe, 21 years of age, who had never menstruated but once, was admitted by my colleague, Mr. Norgate, March 20, 1852, for an ulcer on the leg of some standing. After a month's treatment the ulcer showed but little disposition to heal; and under the impression that it depended upon disorder of the general health, Mr. Norgate transferred the case to me.

On the 26th of April, after having tried steel and aloetic purgatives ineffectually, I prescribed Ol. Sabinæ, gts. viij; Mucil. Acac., oz. j.; Mist. Camph., oz. iij. M. Capt. quartam part., bis die. On the 3rd of May twelve drops were put into the mixture; on the 8th, sixteen; 10th, twenty; 15th, twenty-four; 19th, twenty-eight; 20th, thirty; 24th, thirty-four; 29th, forty; viz., ten drops twice a day. I began to despair of its doing any good, and thought of discharging her; but as her health had in no way suffered, and her leg was somewhat improved, I ordered, on the 1st of June, forty-four drops; on the 7th, forty-eight; on the 10th, fifty-two; viz., thirteen drops twice a day; and on the 11th the nurse told me the catamenia had appeared that morning. She was unwell, in a natural way, as to duration and quantity, and was soon after discharged cured, the ulcer being, I believe, also healed. This woman had the appearance of full health, cheeks full of colour, and body generally in good plight; but she suffered not the slightest ill effect, or indeed any appreciable effect, save that of the occurrence of menstruation, from the savine even in doses much larger than were stated at Mr. Pascoe's trial to be dangerous to life.

CASE III.

Sarah Ann Fisher, aged 15 years. Admitted an out-patient, March 20, 1852, complaining of palpitation and general weakness, with anæmic *bruit*, and amenorrhœa. General appearance that of anæmia, with inclination to fatness, with languid circulation and costive bowels. Ordered aperients and compound steel pills.

April 14th.—No better. Capt. Mist. Ferri. c. Omitt. Pil.

28th.—Has complained of headache since taking the mixture. Mist. Ammon. Gent. Omitt. Mist. Ferri.

May 5th.—Still no improvement, and I advised her to get an in-door recommendation, giving her, meanwhile, Decoct. Cinch. instead of other medicine.

22nd.—She was this day received into the hospital, and menstruation took place a day or two afterwards. I gave her no medicine until June 1st, and then only some æther and gentian for her stomach, intending to wait to see what would take place when she ought next to be unwell. She suffered less from palpitation, and seemed in better health.

June 7th.—She complained of uneasiness in her head and stomach, and of feeling very weak. The

bowels were also very costive.—R. Pil. Col. Rhei, Haust. Mag. Sulph. Steel pills.

25th.—Much the same.—R. Pil. Al. Rhei, Decoct. Cinch.

28th.—Pain in the back to day, but has not yet been unwell. Hip bath.

30th.—Same state.—Ordered croton oil, and Mist. Ferri Comp. instead of pills.

July 15th.—As menstruation had not yet taken place, I began the Ol. Sabinæ, in doses of a drop, twice a day. On the 17th the dose was increased to two drops, on the 19th to three, on the 20th to four, on the 22nd to five. Complaints of weakness, but less of pain in the head and stomach, and says her general health is much better. On the 25th she took six drops, bis die. On the 28th she took seven drops. In the night she had pain in the body, and seemed not so well, but I think it was occasioned by some opening medicine taken the day before, which had acted rather powerfully. On the 31st she took eight drops twice a day, on the 2nd of August nine drops; says she feels rather sick after taking it. Not thinking, however, from the absence of pain in the stomach, that her sickness was produced by the savine, I continued it, giving her on the 9th twelve drops twice a day, but on the 11th she told me she felt sick after every dose, and looked more out of health, so I thought it right to discontinue the medicine for a time, and made her an out-patient, no effect upon the uterus having been obtained from the use of the savine in this instance.

In the hospital I have employed savine only in these three cases at present, but they are sufficient to prove two important facts respecting the drug,—*first*, that it *may* be given with perfect safety in larger doses than those given in Mr. Pascoe's case;* and *secondly*, that, as it succeeded in two out of the three cases, it *ought* to be employed in obstinate cases of amenorrhœa, especially when other more usual methods of treatment have failed.

MY NOTE BOOK.

(No. I.)

By HENRY JOHNSON, M.D., EDIN.,

SENIOR PHYSICIAN TO THE SALOP INFIRMARY.

SILICIOUS DEPOSIT IN THE URINE, SUPPOSED TO BE FROM THE USE OF NEW SPONGE.

SILICIC acid is a well-known constituent of natural urine,† and of urinary calculi;‡ and it is always found in urinary concretions derived from brutes, according to Wurser and Lapaigne.§ But although, on the authority of these names, the occurrence of silex in urinary deposits and concretions may be deemed possible,

* Mr. Pascoe gave four drops and a half three times a day.

† Berzelius.

‡ Rayer and Dr. Yellowby.

§ Urinary Deposits, by Dr. G. Bird, p. 213. 1844.

this event is at any rate extremely rare, and, unless under peculiar circumstances, would be ascribed to accident, fraud, or mistake. I have, however, seen it, where the parties were far above all suspicion of any intention to deceive, and where the patient was too young and *girlish* to be the subject of that morbid *pruritus*, which probably leads to the *voluntary* introduction of foreign substances per vaginam.

As every case is of importance which proves a fact, or points out an obvious source of error, I think the following history is worth recording:—

In 1850 I was desired to examine a small portion of white powder, which I understood was a deposit from urine; it had all the chemical characters of *silex*, and scratched glass with facility. I was informed, that notwithstanding every precaution having been taken to avoid error, more or less of this powder had been found at the bottom of the utensil for about a fortnight. I afterwards saw the patient. She was 11 years old, of spare habit, but tall for her age, and by no means strong. She was subject to sickness and anorexia; the bowels were torpid; the tongue was not clean; the catamenia had never appeared. At the time of my seeing her the silicious deposit had ceased. The urine was pale, had a specific gravity, verging from 1011 to 1031, there was a light mucous cloud in it, and it contained some prismatic crystals of triple phosphate, and on another occasion urate of ammonia and a large quantity of urea. The most distressing symptom was a constant desire to pass water, by day and by night, so that she could not rest, and if the desire was not speedily gratified, the urine escaped involuntarily.

There appeared to be no organic disease present in this case, and the patient ultimately got well without any remarkable symptom, or treatment. I feel quite satisfied that there was here no endeavour to impose upon her medical attendants, either on the part of the patient or her friends. The silicious deposit I have no doubt arose from the use of a *new sponge*. A silicious powder (quartz) is always found in sponge when new, and I have since seen a large quantity of this sort of dust, which had fallen out upon the shelf in a chemist's shop where these articles were kept. It is nearly pure *silex*, because sponges are prepared for sale by being soaked in dilute muriatic acid, which removes calcareous particles, and leaves such as are silicious.

began to suffer from wandering pains in his limbs, from loss of appetite, and general *malaise*. During the course of a week or two he began to lose flesh, became pale, and suddenly lost the power of motion in the right arm and leg. The sensation in these extremities remained intact, and in a day or two the mouth was drawn to the right. Headache then supervened, but gradually, under the judicious treatment of Mr. Pete, of Manningtree, this symptom lost its intensity, the paralysis slowly disappeared, and by Christmas he was able to walk, and soon after to return to his avocations.

On the 29th of April, 1852, he was admitted into the Essex and Colchester Hospital, under my care, with amaurosis of three days' standing. He informed me that early in March he began to lose flesh, to become pale, to lose his appetite, and to have some difficulty in walking in the evening, on account of slight oedema round the ankles. About a week ago his face, became puffy, and his eyelids particularly so. His sight on the 26th began to fail him, and on the morning of the 27th he found himself perfectly blind.

Present state.—April 29th.—A P. is a middle-sized well-made man, rather exsanguine and flabby in his muscular development; has perfect power of locomotion; has a tolerable mental capacity, but is perfectly amaurotic. There is oedema of the eyelids, conjunctive, face, scrotum, penis, and inferior extremities. The irides are perfectly paralysed, no stimulus affects them; no light is distinguished through the greatly-dilated pupils. He does not squint; there is no cataract, glaucoma, or evidence of any kind of organic disease in the eyes. He has no headache, and had none before his sight failed him; neither has he any subjective vision. Hearing, taste, smell, and general sensation, are intact, and he disclaims loss of memory and mental inaptitude of any kind. There is no unusual heat of scalp; the general surface, however, is rather harsh. The tongue is flabby, and rather foul; appetite gone; thirst slight. The lungs present nothing abnormal. The heart and liver, after careful examination, appear healthy. There are no enlarged superficial veins over the abdomen, which, although somewhat large, still appears to be simply oedematous in its parietes. He has no fullness over the renal regions, and has not, nor has he ever had, pain there. Percussion and careful manipulation fail to discover enlargement of either kidney. He has never suffered from vomiting, or from pain along the course of the ureters. He says that his urine has never been scanty nor high coloured, but that, as a rule, it is plentiful, and pale. The bowels are rather constipated; pulse 112, with a singular jerk; urine just passed—specific gravity 1012, acid; smoky-looking sediment; supernatant fluid clear, and straw-coloured; nitric acid rendered the urine slightly turbid: heat more so; a magnifying power of 200 diameters discovered many blood-corpuscles; numerous fibrinous casts of the tubuli uriniferi, some of which were transparent, and others rendered more or less opaque by the adhesion of blood-cells and epithelium; a few epithelium cells and crystals of uric acid.

Hospital Reports.

ESSEX AND COLCHESTER HOSPITAL.

CASE ADMITTED UNDER THE CARE OF P. MARTIN DUNCAN,
M.B., LOND., F.G.S., PHYSICIAN TO THE HOSPITAL.

Disease of the Kidneys, accompanied by Severe Cerebral Disturbance; Cure.

A. P., a man about 46 years of age, of sober habits, had had good health until September, 1851, when he

Having again carefully inquired into the patient's previous history, and having satisfied myself that he had never had ague or purpura, that the kidney symptoms had never been sufficiently prominent to annoy him, that he had no tinnitus aurium or pain in the head, I determined that a subacute nephritis was the origin of the head symptoms. The drain of albumen, and the amount of blood daily passed with the urine, naturally induced a depraved condition of the circulating fluid, and gave rise to dropsy. There was no heart disease; there were no evidences of meningeal or cerebral inflammation. The idea of there being effusion in the ventricles, or at the base of the brain, could not be supported by the symptoms noticed above. My impression was, that owing to the influence of deteriorated blood upon certain parts of the brain in the usual nutritive processes, their functions were not carried out. Why the nervous energy of the irides and optic nerves, and their expansion, should alone suffer, it is hard to say; as is also the reason why there was no strabismus or paralysis of nerves whose origin or course is near to that of those affected.

The man's pallor, and jerking pulse, indicated a considerable amount of bloodlessness, and rather inclined one to the belief that the nephritis was to be checked by the reverse of antiphlogistic remedies. The small quantity of epithelium found in the urine determined that the attack was not of long standing, and the absence of fat globules contraindicated the notion of the incurability of the disease; but the peculiar casts of the tubes, with epithelium attached to them, proved that more than passive hæmaturia was to be feared.

At first the swollen condition of the eyelids and conjunctiva struck me, and an idea suggested itself, that effusion in the orbit might, by its pressure, produce the amaurosis, but there was no prominence of the eyeballs, and their muscles were not paralysed. The prognosis was favourable. The skin around the eyelids was punctured. Middle diet was ordered, and the following prescription:—*R. Tinct. Ferri Sesquichlor., m. xv.; Mist. Camph. oz. iss., fiat haustus quartis horis sumend.*

April 30th.—Edema of the face very considerable; amaurosis perfect; no headache; no sleep; much serum has flowed from the punctures; pulse 112, jerking.—Repeat the punctures and medicine.

May 1st.—The punctures have given exit to much serum; conjunctivæ not so puffy; irides motionless; bowels open yesterday; has not slept since his admission; the little heat of scalp formerly noticed has gone; urine more plentiful, specific gravity 1012, smoky, contained many blood-globules, casts, and numerous fragments of epithelium cells; the brain symptoms are stationary, but there is evidently a change for the better in the renal symptoms; the desquamation from the tubuli uriniferi, (as evinced by the quantity of fragments of epithelium in the urine,) which invariably succeeds to the acuter stages of any inflammatory action in the kidneys, has commenced.

2nd.—He is better to day; oedema less, and he can just distinguish light from darkness; the irides

contract slightly on the sudden application of light. He slept last night. The urine is plentiful, very cloudy, and contains a great deal of epithelium, but few blood corpuscles, and is only slightly albuminous. Pulse 112; tongue cleaner; urine—specific gravity 1012.—Pergat.

3rd.—Has had pain in the loins during the night; urine scanty and high coloured, and highly lithic; oedema nearly gone. He can distinguish figures when close to him; pulse 96; bowels open.

I consider that the alteration in the renal symptoms was due to the sudden congestion of the kidneys, which might have its origin in the reparative process, consequent upon the desquamation of the epithelium cells, in the attempt to perfect a new series. The brain symptoms appeared somewhat better.—Pergat. Dry cup him over the loins.

4th.—During the night, without any previous headache or unconsciousness, the left side of his face became paralysed; sensation still remains. He complains of acute pain along the course of the frontal nerve of the left side. He sees better, there is no strabismus; the tongue is protruded in a right line; there is no deafness nor pain on pressing along the course of the left portio dura. He had no sleep last night; urine clearer; bowels open once yesterday; pulse 112. Deeming the paralysis and pain to be caused by the same influences as those which caused the amaurosis, I continued the iron, and to relieve the pain, ordered leeches to the left forehead.—*Evening.* Sees better; paralysis much the same; motion of extremities perfect; pain relieved by the leeches.

5th.—Amaurosis nearly gone; oedema perfectly so; the irides act naturally; the paralysis still remains; the urine is free from blood corpuscles and contains a few epithelium cells and casts.—Pergat.

6th.—Much the same.

7th.—The paralysis is certainly less; frontal pain gone; urine plentiful—1018, contains fragments of epithelium cells, but neither blood corpuscles nor casts; pallor of face considerable; appetite improved.

11th.—The mouth is scarcely at all drawn to the right; he can shut his left eye well, in fact the paralysis is rapidly disappearing, whilst his colour is returning; his appetite and strength are improving; urine normal.—Pergat.

He progressed for three weeks, became strong, got his colour again, and was discharged in the last week of June, cured.

In this case the treatment was confined to the exhibition of a remedy, which is believed to have a regenerating influence upon the blood corpuscles primarily, and upon the liquor sanguinis, secondarily; it is evident that had the diagnosis been incorrect, that had the amaurosis and paralysis depended upon any other cause than that I have suggested, this constant supply of iron to the blood, would have been exceedingly pernicious, indeed quite as much so, as would have been the exhibition of mercurials or antiphlogistics of any kind after the real nature of the case had become evident.

The concurrence of the renal and cerebral symptoms was singular. When the urine became freer from blood corpuscles and casts, the amaurosis gradually decreased, when an attack of congestion of the kidneys supervened, facial paralysis occurred, and with the return of the urine to its normal state, gradually vanished. We must admit that idiosyncrasy must have had much to do with the facility with which our patient's brain became affected, for it is by no means common to find such severe brain symptoms with the earlier stages of a sub-acute nephritis. The possibility of paralysis occurring without actual cerebral lesion, or pressure, or solution of continuity at some point in the course of the nerve in fault, is a matter of experience. A man, Bacon by name, came into the hospital under my care, with the lower extremities oedematous, the urine highly albuminous, and containing fatty epithelium, and became suddenly paralysed in the left arm and leg; sensation remained. The face was not affected. I examined him carefully several times during the day; the loss of power over the limbs was perfect. In fifty-six hours he had recovered the power of movement to a certain extent. He died from pericarditis some few days after the paralysis had left him. I examined the brain and upper part of the spinal cord most carefully, without finding the least evidence of there being, or having been, sufficient disease to explain the occurrence of so considerable a paralysis. The corpora striata and grey substance generally, were paler than usual. The kidneys were far advanced in Bright's disease. We constantly see the functions of the superficies of the brain partly arrested or perverted, by the action of blood poisons, and the two cases I have recorded appear to demonstrate that other parts of the brain are within the influence of morbid matters in the circulating fluid.

and only a state of uneasiness at the stomach, with debility and emaciation, remained. He presented no other marked symptoms, but gradually declined. He became greatly emaciated, and died.

May 23rd.—His wife informs me that he has had these symptoms for several years; he has been emaciating for at least six years, and has been subject to severe gastralgia for ten. He has never had much appetite in the morning; but he has always been in the habit of getting an appetite by working in the garden, not going to work till ten. He was at one time a very stout well-made man. He has been always temperate in his habits. During my attendance he had frequently very obstinate constipation. He had also some cough, with tenacious expectoration.

Section-cadaveris, forty-eight hours after death.—Some rather recent lymph upon the right lung. The apex of the left lung was more dense than natural; its general appearance was natural, excepting that it was riddled by small branching cavities, which gave it a worm-eaten aspect; there was no appearance of the deposit of any flesh material in the tissue; throughout the lungs were many small firm masses of a white colour, which, when pressed, exuded a matter like thick lymph; the general tissue of the lungs was healthy; but from the secretion there flowed an abundance of dirty serum. The right lung was much in the same state as the left; at the apex the tissue was softening. There was no sign of a tubercle in any part. The other organs were perfectly healthy, excepting the lumbar glands; these were much enlarged, and formed firm tumours, adhering to one another merely by cellular tissue, upon the vertebral column. Some were intimately connected with the pancreas; and they formed a series of nodules around the aorta, lying between it and the vena cava, which they partially surrounded, but were not sufficiently adherent to compress either vessel; the primary branches of the aorta were also surrounded by them; the largest collection formed by them ran along the left side of the aorta down to its bifurcation, in one dense large mass. The mesenteric glands were healthy. The spleen contained a number of firm, small, white bodies, about the size of a millet seed.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.* JULY 1ST, 1852.

GEORGE YATES, ESQ., IN THE CHAIR.

Cancer of the Lumbar Glands, fatal apparently by Pressure upon the Thoracic Duct.—By Dr. RUSSELL.

THOMAS FLETCHER, aged 46, brass-worker, married, died to-day, May 23, 1852. He has been under my care at the dispensary since, and for a considerable time previously under Mr. Welch. He had no symptoms clearly defining his disease; what symptoms he presented admitted of being referred to mere indigestion, except for their persistence, and from their being united with slowly-progressive emaciation. He had pain in the epigastrium, particularly by food; sometimes nausea, seldom vomiting. The pain did not persist,

Constriction of the Rectum by extensive thickening of the Submucous Cellular Tissue, and Infiltration into the surrounding parts.—By Dr. RUSSELL.

Mr. Owen, aged about 64, brush-maker. On the 12th of February, 1852, I was called to meet Mr. Simons to visit this patient. Mr. Simons had been in attendance upon him about three weeks. He first sent for him complaining of diarrhoea, with straining and bearing-down; but after a day or two Mr. Simons found, by directing his stools to be saved, that in eight or ten stools he passed scarce any amount of feces. The irritation in the rectum continued very urgent and troublesome. The patient absolutely refused to permit any examination of the rectum, nor would he allow of an enema. Mr. Simons was, therefore, reduced to the necessity of opening the bowels by medicine, and of

* Continued from page 621.

giving opiates. The medicines, however, acted very imperfectly, and the patient's strength seemed sinking. One day he quite alarmed Mr. Simons by his collapsed state. I found him somewhat easier; there was no sign of fever, or of any disease. He was a spare, wiry man, with a rather florid complexion. He would not admit of any examination of the rectum. With much difficulty I induced him to suffer an enema. This was thrown up effectually, and was repeated; and on the next day but one I was shown a pot nearly filled with foetid stool, containing abundant scybalous lumps. I learn from Mr. Simons that the relief was temporary, that the enema required frequent repetition, and the distress in the rectum continued. A constricted state of the rectum was discovered by the finger passed into the gut. The bowels acted every third day; a considerable quantity of fecal matter being passed in very long masses, about the thickness of a tobacco-pipe. He had discharges of mucus from the rectum, frequently voluntary, to the amount of perhaps two table-spoonfuls three times a day. He sank very gradually, became extremely emaciated, and died June 21st. Before his illness began he suffered from constipation for about eight or ten months; never prominently. He never complained of uneasiness until the period of his illness. He never had piles. When I saw him he would not admit that he had been constipated at all.

Sectio-cadaveris.—Body much emaciated. The abdomen only was examined, and all its contents were quite healthy, excepting the rectum. The intestines having been removed, the sigmoid flexure and the commencement of the rectum was seen to be drawn firmly into a close S-like fold, lying upon the promontory of the sacrum. The rectum was removed from the body. It presented externally its usual appearance, but felt exceedingly dense and firm when pressed by the finger. All the surrounding cellular tissue below the pelvic fasciæ was densely infiltrated, so as to form a hard mass, closely surrounding the rectum. The vesiculæ seminales lay in front of this mass; the right one partly covered, and compressed by infiltration into its surrounding tissue. The ureters were free from it. This firm mass had not compressed the rectum beyond its ordinary capacity, when not distended, below the reflection of the pelvic fascia; but at this point the thickened fascia compressed the intestine, forming a constriction which would only allow of the passage of the little finger. The infiltration had extended up the meso-rectum, greatly thickening and contracting that fold, binding the intestine closely to the sacrum, and by its contraction producing the double fold mentioned above. The small fatty appendages of the rectum were very firm, but presented their usual appearances. The submucous cellular tissue of the rectum was greatly thickened; it presented a semi-transparent aspect, and just the appearance of the non-malignant stricture of the pylorus; just above the anus it was more than half an inch thick. In ascending hence the thickness gradually and uniformly lessened, and ceased altogether at about the commencement of the rectum. The thickness of the mucous membrane, and the infiltrated state

of the surrounding parts, was perfectly uniform entirely, without any of the nodular condition of cancer or any of its irregularity. The mucous membrane was natural, except that it was bound down by the thickening of the submucous cellular tissue; its natural size remained, being rendered permanent by the infiltration. The glandular apparatus of the abdomen was perfectly healthy.

A very Remarkable Case of Fatal Hæmoptysis of Eight Weeks' duration, produced apparently by Bleeding into a Dilated Bronchus, which contained a Large Pulmonary Calculus. The Lung gave way, and caused Pneumothorax.—By Dr. RUSSELL.

Mary Simons, aged 41, married. I first visited her on Saturday, March 20th, 1852. She has been under Mr. Welch since, with very severe hæmoptysis. The hæmoptysis began quite suddenly, just a fortnight before my visit on the Saturday evening. She had not been well during the day, but had been unusually exerting herself in cleaning. She went out of the house in a fit of coughing, and brought up a large quantity of pure blood. During Mr. Fletcher's attendance the expectoration of blood continued, generally tinged with mucus; he saw a pot filled in great part with pure fluid blood. She had had an attack of hæmoptysis thirteen or fourteen years ago, whilst in America, but I could not learn anything of importance respecting it. She had always been delicate, and subject to sickness. Her diet of necessity was of the very plainest material. She had not menstruated for two years. She was a pasty-looking woman; her family consumptive. Unfortunately I did not preserve notes of her case. At my visit I examined her chest; I could not trace any signs of disease in her lungs, nor could I discover from what part the blood was expectorated. The quantity of expectoration had at that time diminished; but to the period of her death (May 8th), it never ceased. During the first ten days it became less, but then suddenly increased to an alarming extent on March 30th, and during two days she expectorated several pots nearly filled with mucus, intermixed with a large quantity of dark blood. The quantity again lessened, but in a few days again renewed itself, and she did not again leave her bed. Excepting in the instances of the copious expectoration of blood and mucus the expectoration was peculiar, consisting of mucus intimately mixed with dark blood, and closely resembling treacle, only that it was more viscid. A small spitting-cup was generally filled by the patient during the course of the day. During the last week its quantity much diminished, and the colour became much paler; and the last two days the matter was described as being like cheese, and very offensive. The general symptoms were those of hæmorrhage, but with a good deal of what appeared like hysteria. Her stomach was exceedingly irritable, so that she took scarcely any food, and rejected her medicine. The retching often occurred without any provocative, and increased the expectoration considerably. Twice this

irritability of stomach followed the use of the acetate of lead, which also produced very troublesome constipation—a state which created much difficulty in the treatment. During the last ten days she suffered much from severe pain in the right shoulder, and upwards, over the entire right chest, which was partially relieved by a blister. I could not ascertain the state of her chest by examination for some time after her state assumed so serious an aspect, on account of the violent retching and eructation excited the moment she sat up. At one examination, a day or two after her first relapse, I still found the breathing natural on both sides; but within three weeks of her death, I found entire absence of breathing in the front of the right side; and at the only effectual examination of the posterior region behind also, in the left the breathing was puerile. She never suffered much from cough. Her death was rather sudden on May 8th. She had a complete hæmorrhagic aspect. Urine was free from albumen.

Section-cadaveris sixty hours after death.—Chest: The only part examined, except the stomach, which was pale, but otherwise healthy. Left lung perfectly healthy; it had extended itself behind the sternum, as had been indicated during life; it was perfectly free from tubercle. Some diffuent gruel-like mucus oozed from the small tubes, and was also found in some quantity in the large tubes. The right lung was collapsed upon the spine. The chest was less than half filled with sanious purulent fluid, resembling raspberry cream. The pleuræ were coated with a thick false membrane, removed with much difficulty, leaving the pleura quite clear and shining; its deep layer was semi-transparent, the superficial layer white and opaque, and had more of the character of having been deposited from the fluid poured into the chest. There was no difficulty in removing the lung entire; it had no adhesions of any resisting power; and after it had been removed we found in the chest masses of what seemed soft friable fibrin, of the colour of the fluid in which they were immersed. In front of the lung, near the base of the middle lobe, there was a fissure near an inch in length, and when the finger was introduced into this fissure, it came in contact with a rough stone-like body, lying near the root of the lung. This we found to be a hard body of exceedingly irregular figure, rather more than half an inch in its long diameter (7/12^{ths}); its surface very rough; it was hollow, and as if worm-eaten; its appearance was between that of a piece of necrosed bone and a piece of mortar, very light. It lay in a cavity connected with one of the primary subdivisions of the right bronchus, and was embedded in pulmonary tissue, just at the root of the lung. The bronchus ended abruptly at this cavity, and its cartilaginous rings, ragged and uneven, projected into it, as though divided at the spot. The cavity was empty of fluid, nor could I detect any communication between it and a blood-vessel; the pulmonary artery lay close behind it, and one small branch given off from the artery was separated from the cavity by so delicate a membrane that the end of a probe could be seen through it quite distinctly. In another of the primary

subdivisions of the same bronchus, was a second concretion, exactly like the last, only smaller; it quite filled up the cavity of the tube, which was a little dilated at the spot, but the walls of the tube were entire. The concretion was situated at about two inches from the origin of the tube. A third concretion was embedded in the pulmonary tissue, without having any communication with a bronchial tube; it lay close to the last-mentioned calculus, but differed from it in being moist and soft, therein resembling mortar. The pulmonary tissue was healthy; it did not contain a single tubercle. The lung did not admit of being inflated, and a slice from it sank in water.

METROPOLITAN COUNTIES BRANCH.

THIS Branch held its preliminary meeting at 37, Great Queen Street, Lincoln's Inn Fields, November 26, 1852, Dr. FORBES in the chair. Among the members present were—Dr. Take, Chiswick; Dr. Cormack, Putney; Dr. Ogier Ward, Kensington; Dr. Conolly, Hanwell; H. Hanks, Esq., Albert Square; G. Bury, Esq., Whetstone; C. T. Carter, Esq., Hadley; B. W. Richardson, Esq., Mortlake; Dr. Howard, Weymouth Street; E. Ray, Esq., Dulwich; J. B. Brown, Esq., Connaught Square; J. Probert, Esq., 6, New Cavendish Street; Thomas Hunt, Esq., 23, Alfred Place, Bedford Square; Henry Thompson, Esq., M.B., 16, Wimpole Street, Cavendish Square, &c., &c.

Dr. FORBES having opened the proceedings, called upon Dr. Ogier Ward, who was appointed Secretary *pro tem.*, to explain the objects of the meeting.

The SECRETARY then stated, that a closer union of the members of the Association, residing in and around London, having always appeared to him to be desirable for the welfare of the Association, he had adopted, with alacrity, the suggestion of forming a branch for this purpose, and having communicated with Sir Charles Hastings and Mr. Sheppard, he was happy to find that the proposal met with their fullest sanction and approbation; he therefore had addressed circulars to all the members residing in Middlesex and the immediate vicinity of London, and had received so many replies in favour of the plan, that he had been induced to persevere, and had requested the attendance and co-operation of the members on the present occasion. The Secretary added, that he had observed with much interest the formation of medico-ethical associations in various parts of the kingdom, and that the establishment of a similar society in connection with this Branch, was one of the objects he hoped to see carried out at no distant period.

The following resolution was then carried unanimously:—

“That the members of the Provincial Medical and Surgical Association now present do, in accordance with the laws of the Association, form themselves into a district branch, under the name of the Metropolitan Counties Branch, and that the limits of this Branch do comprise the county of Middlesex, and such parts of Essex, Kent, Surrey, and the adjoining counties, as are not included in any existing branch.”

In proposing this resolution, Dr. CORMACK mentioned that he had forwarded to the Central Council, for admission, the names of above sixty gentlemen who were anxious to join the Association, and he believed that many other members had met with great success in their attempts to benefit the Association, by increasing the number of its members.

The "Rules for District Branches" having been read, and some modifications introduced into them, it was resolved,—

"That the rules just read for the district branches, with the modifications introduced in conformity with the laws of the General Association, be adopted, and submitted for the approval of the Central Council."

The next proposition, for the *ad interim* management of the Branch was to the following effect,—

"That a Provisional Committee of six members, and the Secretary, be appointed to conduct the affairs of this Branch till the general meeting."

In discussing this resolution, a question arose,—whether the members of another branch present at this meeting, were entitled to vote on the proceedings, or whether they must disconnect themselves from the branch to which they have been hitherto attached,—in short, whether a member can belong to several branches at the same time. This point was referred to the Central Council for its decision.

A Provisional Committee of the following six gentlemen, with the Secretary, was then appointed:—Dr. Forbes, Dr. Sibson, Dr. Cormack, B. W. Richardson, Esq., J. Probert, Esq., J. Bowling, Esq.

The first general meeting of the Branch was then fixed to be held not later than Tuesday, January 11th, 1853, at a place, and time, to be settled by the Committee, and the meeting then separated, after a hearty and unanimous vote of thanks to the President, Dr. Forbes.

The alterations in the "Rules for District Branches" referred to, are the following:—

3rd Rule. After majority, insert "*present*."

4th. "*An*" honorary secretary, and "*not less than six, nor more than fifteen*" members in addition, &c.

5th. After held "*at least once*"—and, at such place as "*a general meeting of the*" members; also, and "*that extraordinary meetings may at any time be called by the Council of the branch by a notice published in the Journal ten days before such meeting.*"

8th. Add, "*and that not more than two-thirds of the Council be re-elected.*"

9th. That the members dine together at the annual meeting.

EPIDEMIOLOGICAL SOCIETY.

THE opening meeting of the third session which, was very fully attended, was held at the house of the Royal Medical and Chirurgical Society on the evening of Monday, the 1st instant, when a very eloquent address was delivered by Dr. Babington, the President of the Society, concluding with an account of the pro-

gress of the various Committees of the Society in the investigation of the subjects respectively entrusted to them. As but a faint idea of Dr. Babington's admirable address could be formed from a mere abstract of its contents, we shall, on a future occasion, present it entire to our readers.

Dr. BABINGTON next read a paper by Dr. SWAINE, "On an Epidemic '*Suetto Miliare*,' in the Hérault," of which the following is an abstract:—

Dr. Swaine begins by defining '*suetto miliare*, as an epidemic fever of a remittent type and a typhoid form, attended by profuse sweating, and for the most part with an extensive eruption of miliary vesicles.

Dr. S. stated that he believed that the disease in its present form had been known on the Continent before the commencement of the eighteenth century, and accurately described by Bellot during the fourth decennium of last century. It had recurred from time to time in various parts of France, always selecting damp, poverty-stricken and ill-drained localities for its visitation. In 1821, the centre of France became a prey to its ravages; and that patient and acute observer, M. Rayer, was then commissioned by his Government to investigate and report upon the disease. This report was most comprehensive, and most welcome. Unfortunately, however, it appeared under the banner of Broussais-isme, which deprives it of a portion of its value at the present day. It was not until 1851 that the Hérault became visited by this pestilence. It first broke out in a village situate on the declivity of a hill, sheltered by mountains more or less elevated from all but the south wind, which reaches it with the malaria of a marsh district on its wings. The village is dirty and viciously drained, the refuse of many small distilleries contributing to its insalubrity. The inhabitants are poor and prejudiced. Here the disease appeared spontaneously in the early spring. Many were attacked, and a few died. To the end of this village rises a lofty volcanic plateau, twelve miles long and two broad. Over this range the disease seemed to make a leap, attacking secondly with great and deadly violence a village lying at the other end of the plateau.

Although without any regular order in its march, the epidemic afterwards attacked in succession all the villages and towns situated around the base of the said plateau (*les causses*), and in fact seemed to confine itself almost entirely to one hydrographic basin, the bed of the river Hérault, and of certain of its tributaries.

No facts are recorded which render it very probable that the disease is propagated by contagion. It is, however, stated that it sometimes passed from village to village in the teeth of the prevailing winds. The people, however, and even the rural practitioners, mostly believed in contagion; and it required nothing less than a scenic display on the part of a Government Commissioner to reassure the panic-stricken inhabitants of the affected district on this point.

The etiology of the disease remains obscure. A specific telluric influence must be supposed to be superadded to the general miasmatic tendency of the affected communes. The epidemic generally sets in in early spring, when the peasantry, male and female, are engaged in laborious field-work under a broiling sun, and often with a piercing wind blowing upon them from the snow

mountains of the Cévenues; whilst the sweating method of treatment is at all times, and for the cure of nearly all diseases, carried to its utmost limits. The nature of the disease is, if possible, still more obscure. French physicians have uniformly applied the pathological theories current in their own day to the explanation of this disease. Dr. Swaine felt more inclined to adopt Prout's view of analogous fevers attended with profuse sweating, namely, that an excessive quantity of lactic acid is generated within the system and excreted by diaphoresis. The almost exclusively vegetable and mild diet of the peasantry in the Hérault seems to Dr. S. to favour this assumption, and he thinks that in the so-termed malignant cases, the excess of lactic acid in the circulation may be so great as to overwhelm the nervous centres.

An account is then given of the disease itself, which differs from other typhoid fevers chiefly in this, that an enormous amount of sour fluid is poured off from the skin, and that in many instances—not in all—a miliary eruption appears after a few days of these profuse sweats. It is important, however, to observe, that neither the fever nor the course of the disease is at all modified by this efflorescence.

The distinction of two forms of the disease seems to Dr. S. simply convenient, but not founded in any real difference, except in degree. Mild cases of the disease often become suddenly and very unexpectedly malignant, and the patient dies comatose or convulsed, in spite of every variety of treatment.

Other cases show this intensity from the first, and a few days, or even hours, decides them in a fatal sense. *Post-mortem* examinations throw no light upon these cases beyond establishing plethora of the venous system, and a generally diffuent and black condition of the blood.

In 1821 Rayer and others practised the antiphlogistic treatment to its full extent. At the present day immense doses of quinine are given,—larger in proportion as the disease is intense. The proportion of deaths seems to be pretty equal under these two opposite poles of indication, and it is hard to suppress a smile at the zeal and confidence with which such different methods are advocated by their respective adherents.

Of the statistics of the Hérault epidemic little is as yet known.

Dr. S. concludes his paper with a brief parallel between the *suette miliary* of this and the last century and the English sweating sickness of the middle ages.

Dr. S. dissented from the opinion of Hecker, who regards the two diseases as essentially different, and himself considers that there is enough analogy between the two to justify us in classifying them together, admitting only that greater degree of intensity in the earlier disease, which might well be accounted for by the differential character of the two races, of their respective habits and customs, and especially by the different age of civilization under which the English sweating sickness occurred.

The address of the President, and other preliminary business connected with the Society, with the reading of Dr. Swaine's most interesting paper, having occupied the meeting until a quarter-past ten o'clock, no time was left for discussion on the paper, and the proceed-

ings of the evening were concluded by the President announcing that a paper "On the influence of noxious effluvia as to the origin and propagation of Epidemic Diseases," by R. D. Grainger, Esq., would be read at the meeting in December.

Correspondence.

THE MEDICAL BILL.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—According to the wording of the 24th clause of the amended Draft, it appears to me that unregistered practitioners will be able to find a loop hole for illegal practice. It there says:—"That if any person after the 1st day of February, 1854, act or practise as a physician, surgeon, apothecary, or licentiate in medicine, in any part of the united kingdom, without being duly registered according to the provisions of this act," &c., &c., "he shall, on conviction before any magistrate, having jurisdiction in the county, city, or place where the offence was committed, forfeit and pay a sum not exceeding £5, nor less than forty shillings," &c. &c. I beg to suggest, that instead of the words—"act or practise as physician, surgeon, apothecary, or licentiate in medicine," the words—"practise medicine," be used, and for the following reasons:—1st. In the interpretation clause the word "medicine" is intended to signify "medicine, surgery, midwifery, and pharmacy," so that all persons illegally practising any of these, will be brought under the operation of the act whatever name they may assume, and without the necessity of specifying the particular branch in which they practise. 2ndly. No definition of what constitutes the practising as "physician, surgeon, apothecary, or licentiate in medicine," is given in the Draft, consequently it might be open to doubt whether persons practising under other titles, (homœopath, hydropath, thermopath, Coffinite, Thomsonite, accoucheur, midwife, bonesetter, *et hoc genus omne*,) or even those using no designation at all, could be brought under the operation of the 26th clause, if defended by an acute counsel, or the case were heard before an unwilling magistrate; and that there are many such, we know too well, as our magistrates are derived from those classes which are the great supporters of quackery. The substitution of the word "medicine," in addition to being much more simple and comprehensive would do away with the necessity of defining in courts of justice, what constitutes practising as physician, surgeon, &c., a difficulty which you are aware for many years frustrated the operation of the penalty clause in the Apothecaries' Act. I trust, however, that the wording of the proposed act will be such as not to admit of evasion or equivocation.

It will be perceived also that the 30th clause could be easily evaded by unregistered practitioners. Thousands of persons practise medicine who do not use the "name or title of physician, doctor, bachelor of medicine, surgeon, or apothecary," and upon such persons this clause would be inoperative, and while, as before re-

marked, the same persons, by calling themselves by other names, or using no designation at all, might evade the operation of the 26th clause. Any legal gentleman who could "split a hair," would promise his client a verdict "on this nice point," and make it "perfectly clear" to the country magistrate.

I object also to the use of the word apothecary, which appears to be unnecessarily introduced. "Apothecaries" being registered as "surgeons" by the proposed Act, a name would be perpetuated which in a few years would be quite obsolete among the profession and the public, or, at all events, it would resume its original signification, and be confounded with the functions of the "pharmaceutical chemist," which it is well to avoid, and which may be avoided, since the word *medicine* is intended to include "medicine and pharmacy." There are many quacks of large practice who would not be deterred by anything contained in the proposed Act. Forty shillings and not exceeding five pounds is a penalty which would have no influence in deterring men who have set at naught far more stringent provisions in the Apothecaries' Act. They would consider their immunity cheaply purchased at a dozen such penalties per annum; particularly when their enforcement is entirely left to the public spirit of medical practitioners, neighbours of the delinquents, a most unenviable duty, which very few would be found to perform, and none without incurring much personal sacrifice, and questionable notoriety. Of course, under these circumstances the quack would go scatheless. He has braved the Apothecaries' Act with impunity,—he would laugh at the tender provisions of the proposed Act. I would suggest that a public prosecutor be appointed under the Act, or it might be made compulsory on the Registrar or Council to prosecute, on the complaint of two or three registered practitioners, or half the penalty might be given to common informers. Certainly some readier and more practicable mode must be adopted than that proposed. One penalty per annum would be no punishment, and yet it does not say that it may be repeated. I have been chiefly impelled to urge on the Bill Committee the reconsideration of the clauses I have commented on from the fact that in the amended Draft the provident clauses are omitted. I feel exceedingly sorry for this omission, but doubt not the Committee have been influenced to it only after valid reasons and mature consideration. A vast number of our brethren are struggling with poverty palpable, and as matters at present stand, irremediable, having a humiliating influence on the mind, which ill becomes educated men, depreciating them in the eyes of the public; prostrating their energies, mental, moral, and professional. Many, deploring the circumstances which compel them to debase a noble calling, under the honourable and scientific pursuit of which they can barely live, feel constrained to pursue practices to which "their poverty and not their *will* consents." How painful to see every year some hundreds of young men highly educated, and with noble aspirations, enter our ranks, many of whom, we feel assured, are doomed to bitter but undeserved, I had almost said unavoidable, disappointment. This ought not to be so—it need not be so—if, as in the legal profession, we but adopt measures for securing our rights from unlawful invasion. Instead of

being proverbially a "poor profession," we should be a wealthy one, and have little necessity for provident and benevolent institutions, but which, when required, would be abundantly and cheerfully supported. At present nothing shows our poverty more plainly than the fact that the demand for institutions of this kind greatly exceeds our ability to supply. The few that are in existence being inadequately supported, and not subscribed to by a tenth of the profession. If the means for supplying this want proposed in the original Draft be withdrawn, our independence can only be maintained by such a reconstruction of the clauses to which I have alluded as will render their application easy, and their evasion impossible.

I cannot close my letter without offering my warmest and most heartfelt thanks to Mr. Hastings and the Bill Committee, whose zeal and energy in the cause I hope may be crowned with success.

F.R.C.S.

THE BRITISH GRADUATES AND THE PROPOSED NEW CHARTER OF THE COLLEGE OF PHYSICIANS.

[We have received the following correspondence from Dr. Tunstall for publication:—]

Bath, Queen's Parade Place,
November, 1852.

DEAR SIR,—The Committee of British Graduates appointed at the general meeting held at Oxford on the 22nd July last, "to communicate with the Royal College of Physicians in relation to the proposed new Charter," have great satisfaction in forwarding you a copy of a communication, received from Dr. Hawkins, in reply to a letter containing the resolutions unanimously passed at the meeting at Oxford.

They at the same time desire to offer their sincere congratulations to their fellow graduates on the kind and conciliatory spirit shown to their suggestions by the College.

It is, however, absolutely necessary that all British physicians now practising in England and Wales without the diploma of the College should heartily unite in strengthening the efforts of the College for the remission of the stamp duties.

The Committee earnestly hope that you will assist them in their efforts to aid the College to procure a remission of "*a tax which, compared with other analogous stamp duties, does appear to be disproportionately heavy.*"

To do this effectually, your Committee would urge the necessity of forming branch Committees to co-operate with them. First, to memorialize the College again to remonstrate against "*an impost pressing on it so heavily.*" Secondly, to memorialize Her Majesty's Government praying for the remission of a tax which, in a great degree, tends to prevent the British physician not practising in London from becoming a member of the College; and thirdly, if necessary, to petition the House of Commons against an impost which, while it adds but little to the revenues of the country, presses severely upon a class of men ready at all times in

hospitals and dispensaries to devote their time and talents gratuitously in the service of their sick and afflicted fellow-subjects.

In conclusion, I have to inform you that some necessary expenses must be incurred by your Committee, for which no funds are available; I am, therefore, directed by them to solicit subscriptions, so that by the earnest co-operation of the provincial physicians, the College may be enabled to procure a Charter, which, inflicting no injury upon any class, will be the means of uniting us all in one Royal Incorporation, but of the manifest advantage not only of the profession but of the country at large.

I have the honour to be, dear Sir,

Your faithful Servant,

JAMES TUNSTALL, M.D., EDIN.,
Honorary Secretary.

Royal College of Physicians, London,
Nov. 11th, 1852.

SIR,—I am directed by the Charter Committee of the Royal College of Physicians, to request that you would communicate to the British Graduates in Medicine, who held a meeting at Oxford on the 22nd of July, 1852, that the Committee has taken the earliest opportunity which offered itself after the recess, of considering the resolution passed at that meeting, a copy of which you have been good enough to forward to the College; and, further, that you would assure the British Graduates that it is highly gratifying to the President and the Committee, as it will be, doubtless, to the Fellows at large, to learn that the provisions of the proposed new Charter for the College, were thought by the meeting to be extremely liberal.

With respect to the suggestions contained in the Resolutions, viz.—“Whether the clause relating to the fees payable upon admission to membership by those who, at the date of the Charter, are Graduates in Medicine of British Universities, be not open for reconsideration, with the view of reducing the amount to be paid for the diploma itself, especially by those who have long practised beyond the jurisdiction of the College; and of endeavouring to exempt all candidates, being Graduates of British Universities, from payment of £15 stamp duty, they having already paid a stamp duty on taking their degree,”—the Committee deem it right to offer the following considerations:—

That the College of Physicians has public offices to discharge, and officers to remunerate, towards which it neither receives, nor ever has received, any payment or pecuniary assistance whatsoever from Parliament or the Government.

That the only endowment which the College possesses consists of bequests from some of its former Fellows, not sufficient for its ordinary services and for keeping the building in repair; the building itself having been erected chiefly by means of the private subscriptions of some of the former and of the present Fellows.

The necessity, therefore, that those who receive licenses from the college should contribute towards its support, is obvious; and it may be stated that the sum hitherto payable for this purpose by every Licentiate

has been somewhat more than £40, exclusive of stamp duty. This sum has been paid although the license did not formerly confer the same eligibility as at present to the Fellowship. And every Licentiate must at that time have paid, in addition, fees (and probably stamp duty), to some university, because a degree was, until lately, an indispensable requisite for the license.

Even the Extra-Licentiates, who practise beyond the proper jurisdiction of the College, many of them being Graduates of British Universities, have each contributed about £20 to the College.

But for several years the number of licenses annually sought and paid for has been smaller than heretofore, because many physicians have been waiting in expectation that a new Charter would be granted to the College. Whilst, in the mean time, the College has already incurred considerable expense, and must incur expenses to a much larger amount, in order to obtain a new Charter from the Crown, and an Act of Parliament, without which the Crown has not the power to grant a Charter to the College. It seems but fair that these expenses should be defrayed at least in part by those who are to obtain by means of this Charter both legal rights and corporate privileges.

When first the proposition was made by the College to receive as members, under a new Charter, all British Graduates properly qualified, without examination, and at a reduced fee; that fee is fixed at £25. Readily, at the suggestion of the Council of the Provincial Medical and Surgical Association, it was further reduced to £15.

The Committee, taking all the circumstances now stated into consideration, would not feel itself justified, in recommending the College to reduce the fee still further.

With respect to the exorbitant stamp duty of £15 on every license, and £25 on the diploma of every Fellow, the College is not assuredly a consenting party to an impost pressing upon it so heavily. It has several times remonstrated against it. It will be ready to co-operate heartily with the British Graduates in the endeavour to persuade the Legislature to remove or lighten a tax which, compared with other analogous stamp duties, does appear to be disproportionately heavy. Whilst, on the other hand, the conciliatory tone of the resolution encourages the Committee to hope that the College will meet with the cordial co-operation of the British Graduates in the attempt to obtain the proposed new Charter.

I have the honour to be, Sir,

Your most obedient Servant,

FRANCIS HAWKINS, M.D.,

REGISTRAR.

To James Tunstall, Esq., M.D., &c., Bath.

ON THE REPRESENTATION IN PARLIAMENT OF THE MEDICAL PROFESSION.

To the Council of the Provincial Medical and Surgical Association.

GENTLEMEN,—Permit me to call your attention to a letter which was published in the *Morning Chronicle*,

on Tuesday, November 9th. It was written by Mr. Dickinson, of Kings Weston, in this county, a large landed proprietor, and formerly one of the representatives of the western division of the county. The letter refers to the four vacant seats in the House of Commons, and the writer proposes that they should be appropriated as follows:—One to be filled by a representative of the University of London, and the other three by representatives elected by members of the medical profession. There is an increasing feeling in the profession that it ought to be represented in Parliament, and the present is a most appropriate time, in my judgment, to appeal to the Government and to the House of Commons in the matter, and surely the Provincial Medical and Surgical Association, through its Council, is the most suitable body in the profession to take the necessary steps. I would therefore ask your earnest and early attention to the subject, in the hope that you will determine to aid us in obtaining what seems to me to be justly due to us as a profession.

I am, Gentlemen,

Respectfully yours,

F. H. WOODFORDE,

Taunton, November, 1852.

P.S. I should wish, if you approve it, to insert this letter, with Dr. D's., in our journal.

"To the Editor of the Morning Chronicle."

"Sir,—I see it stated in your paper that the Graduates of the University of London—I wish I could call them the Senate—are about to renew their application to Parliament to be allowed at least one representative when the four seats now vacant are disposed of. This request is reasonable, and modestly put; in my opinion it would be but an instalment of their claims, for the State ought to place this new body on a par with the old Universities in all that concerns rights and privileges, and to endow it with revenues considerably greater than the richest College in either of them.

"You inserted last Spring some letters of mine in which I advocated the assignment of two seats to this University, in connection with a large plan for giving the franchise to various learned professions, with a view to balance, by a representation of intellect and education, the representation of mere numbers.

"I think this plan of importance, because it would render household suffrage safe and wholesome; but it does not do in this country to propose a comprehensive plan, which makes large changes necessary. I have made a mistake, and bow to the wisdom of our national habits, which prefer an experiment on a small scale first, such as we can extend if it succeeds, or retreat from if it fails.

"I am anxious, therefore, to propose that one seat should be allotted to the University of London, and three to the medical profession. I stated at length in my letter of May 19th reasons why the medical profession needs representatives of its own in Parliament, and showed that it was likely to choose Members who would know the wants of the people, and yet not blindly yield to them; and thus act with true humanity, while they would have a care for the interests of science, which Parliament, as now constituted, is but too apt to neglect.

I stated also the mode in which the elections might be managed, which I will recapitulate.

"There must be a register of medical men practising as physicians, surgeons, and apothecaries in the United Kingdom. It would undergo an annual scrutiny; and I conclude that the profession might be trusted to see that the names of those who had given up practice or were dead, were expunged, and the medical men themselves to make their claims, and see that their residences are correctly stated. The 'Medical Register' would, of course, be published annually.

"I pointed out in my former letters the advantage of letting the votes be given cumulatively, each voter giving as many of his votes as he chooses to one man. This has been so much insisted on by others, before and since, as a means of protecting minorities, that I shall not say more about it now.

"At the time of the election, each person named in the register would have his polling-paper sent to him by post, containing the names of the candidates nominated to the returning-officer in London. He would mark in it how he desired to dispose of his three votes, sign the paper, and return it. Everyone is familiar with this process, by which the elections to various charities are performed. There would be a slight risk of letters being received and returned by the wrong person; but this kind of roguery would be but a small per centage on the whole, and could not be systematized. And I am inclined to think that there would be less failure through undue or corrupt influence upon this plan than upon the common one.

"I venture to think that it would be far better to give the seats as I propose than to any large constituencies. We should avoid stirring again the rivalry of classes, whose feuds are not wholly pacified; we should be doing an act of justice to an institution of great and increasing importance, and to a profession which cannot now make itself heard in Parliament; and should introduce into it men whom no party would have reason to fear.

"I remain, Sir, your obedient servant,
"F. H. DICKINSON."

THE CASE OF MR. COX.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—A statement I made at the Bristol meeting would, I think, be more correctly reported thus:—"As to the operations, a young man whom he (Mr. Barrett) saw at the court, and whom he believed to be a dispenser at the Western Dispensary, named Biggs, had admitted to him immediately after the trial, that in Bourn's case the bougie had been passed." This makes my statement rather stronger, and I request you will insert it in your next, in reply to a communication in your last. It could not have originated in mistake, and on my part was no mistake.

I am, Sir,
Your obedient Servant,
JOHN BARRETT, F.R.C.S.

Bath, 13, Pierrepont Street,
November 30, 1852.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—The letter in the last *Journal*, of the five medical gentlemen who gave evidence against me, necessitates my laying before your readers the testimony they gave. I need not notice the evidence of Mr. Topp, for on this occasion he dissociates himself from the other medical gentlemen. I, therefore, will commence with the second medical witness, Mr. C. A. Harries, who says:—"He never during his practice saw the two diseases described coexisting in the same patient;" "no practitioner in France, England, or elsewhere, ever heard of such a case;" "had never seen the two diseases coexist, and the best authors agree in the opinion that they do not." "Sir Astley Cooper was out of fashion now. Sir Astley Cooper and Mr. Hunter would have said 'aye' to this question. Mr. Lawrence, and the writers of the present day, would say 'nay.'" Mr. Skeate follows Mr. Harries, and to the fairness and proper feeling with which he gave his evidence I take this and every other opportunity of testifying. He, however, says, (I doubt not with perfect good faith):—"I never saw a case in which the two diseases coexisted together." Mr. Field is then called, and says:—"He could not have walked without limping, if he had had a bubo; he did not walk limping; never saw a case with the symptoms described coexisting; it is possible the two diseases may be contemporaneous, but (with great emphasis) in all my experience I never witnessed it." Mr. Bartrum was then called; and he is reported to have agreed with the other medical witnesses. But he also said what I repeated before him at the Bristol meeting, and what he did not then attempt to dispute, "If a patient had phimosis, a bougie could not be passed." On being asked why, he said:—"Because there would be inflammation of the glans penis." And then being asked if inflammation of the glans existed in natural phimosis, he said:—"No, that is a natural state of things." Mr. E. L. Bagshawe winds up the medical evidence by saying:—"I do not believe that the whole of the diseases mentioned existed at the same time." Upon this medical evidence the Judge charges the Jury "that not less than six medical gentlemen of experience and repute had been called to give an opinion on that bill. As one witness after another was called, they all agreed that they did not believe that such a case ever existed;"—"They did not believe that the diseases which were specified upon the face of the bill ever could coexist in the same patient." See *Bath and Cheltenham Gazette*, Sept. 8th, 1852.

This, then, was the medical evidence given by these witnesses. And I ask,—Is it worthy of members of a profession called honourable, to shift the responsibility of it, by the quibble that they did not assert that syphilis and gonorrhœa could not possibly coexist? Was not this the legitimate deduction from their evidence, and the conclusion which an unprofessional auditory must draw therefrom. Of this there can be no doubt. They appear to have been led astray by Mr. Topp, who boldly asserted that gonorrhœa gave an immunity from syphilis, and in their zeal for the professional honour, they gave evidence which I challenged them at the Bristol meeting, before professional men, to maintain. I again challenge

them to do so, or to deny that they gave this evidence. Let them meet me fairly either by saying that they had been inadvertently led astray by Mr. Topp, and thus make me the only reparation now in their power for the injury they have done me; or let them come forth and say the evidence we gave we still believe to be true, and are prepared to maintain. But let them not think to escape by the miserable quibble, that they did not assert that syphilis and gonorrhœa could not possibly coexist.

These gentlemen say they went to the trial without any communication with the plaintiff. Had they no communication previous to the trial with the plaintiff's son-in-law?

They also pledge their veracity that the Jury were not influenced by their opinions as to the coexistence of gonorrhœa and syphilis. But I assert, that those five gentlemen cannot themselves, on calmly reflecting on the whole evidence given at the trial, believe the Jury were uninfluenced by this opinion. Neither will any other person, viewing the whole evidence, doubt that the Jury must have been strongly prejudiced by the decision against me. At present, Sir, I have no more to say to these gentlemen, but shall be prepared to reply to anything they may have to advance in further justification of their evidence.

I am, Sir, your obedient servant,

W. A. COX.

Bath, December 2, 1852.

[We insert the above letter, because we are anxious that Mr. Cox should have every opportunity of defending himself, but as he has now withdrawn from the Association, we cannot insert any further communications from him. We have also received the report of the Bath and Bristol Branch Meeting, but as it would occupy nearly twenty pages of the *Journal*, we are obliged to postpone its insertion to our next number.—ED. J.]

URGENT CASE OF DISTRESS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In returning you my most grateful acknowledgements for your kind courtesy, in inserting my letter in your last journal, I hope I shall not be deemed trespassing too much upon your kindness, if I beg for an extension of that indulgence, in order that through the same medium I may offer my warmest thanks to those ladies who have most generously and affectionately responded to my appeal on behalf of the "Urgent Case of Distress" advertised in your two last Journals. I am sure it will gratify them to know, that the sums already received amount to £5. 11s. 1d.; and I earnestly hope and believe, that as the case meets the eye of other ladies, they also will unite with us in the blessed privilege of helping the widow and the fatherless in the hour of need.

I am, Sir, your obedient servant,

CAROLINE NEWNHAM.

Farnham, December 4, 1852.

Reviews.

Some Observations on the Contamination of Water by the Poison of Lead, and its Effects on the Human Body, &c., &c. By JAMES BOWER HARRISON, M.R.C.S.L., &c., &c.

IF the profession is well acquainted with the poisonous effects of lead taken in minute quantities, as a matter of science, we may be permitted to doubt whether it does not frequently overlook the question in the treatment of various obscure and anomalous cases, as a matter of practice. It is the object of this volume to place the facts so strongly before us, that for the future neither doctor nor patient can fail to have his suspicion excited whenever circumstances render it possible for the poison of lead to have been insidiously introduced into the system. How constantly this possibility exists where it is little thought of, how various are the modes by which the risk is incurred, the author makes sufficiently plain. He justly lays considerable stress upon the interesting observation of Dr. Christison, that water dissolves metallic lead in direct ratio to its own purity, pure rain water, devoid of salts, corroding lead more than spring water, distilled water more still. Hence rain water, collected and preserved in leaden cisterns, is certain to contain an injurious amount of lead in a state of solution; whilst spring water, especially if hard in quality, is less likely to be contaminated. The explanation is not that hard water does not act at all on the surface of the leaden cistern or pipe, but that the chlorides, sulphates, and phosphates of lime, which give the water its hardness, yield up their acids to the lead, and form insoluble salts, which for the most part encrust the surface of the metal; hence, a new cistern or pipe is more likely to contaminate water than an old one, of which the surface has become thus covered over with insoluble salts. Still there is abundant proof in the volume before us, that leaden pipes are not to be trusted for the conveyance of spring water, especially perhaps when the water of the spring has not percolated limestone strata. Many instances are given wherein the mischief was due to the use of leaden pumps for spring water. More commonly, however, it happens, that the rain water and the leaden cistern are the mischief-mongers.

The author has taken the pains to inquire closely into the domestic arrangements, in many cases, in which the possibility of lead-contamination was denied, and found (as in other examples where medical conclusions depend upon non-medical evidence,) ample proof of the justness of his anticipations. The very amusing narrative of his experience in this line, is as entertaining as it is instructive. The customary dissatisfaction of the lady of the house at the question being put at all, the equivocation of the subordinate, and, sooth to say, the evident coolness of all parties when the truth was sifted out, the cure of the sufferer notwithstanding, remind us of a heathen proverb, to be found somewhere in the old Latin vocabularies—"He who follows truth too close to her heels, shall have dust cast in his face."

We should bear in mind, that lead *may be* the *fons et origo mali* in all puzzling cases of sudden colic, habitual constipation, wandering pains in the limbs, emaciation, unsteady muscular action, occasional vomiting, dyspepsy in general, dirty yellow tinge of skin, wasted and partially paralysed muscles, epileptic convulsions, delirium, and coma. But the symptoms most characteristic of poisoning by lead, are constipation, abdominal pain, and vomiting; pain in the part of the lower spine, and a failure in muscular power. A marked sign, which may or may not be present, is the blue colour of the margin of the gums, especially pointed out by Dr. Burton.

We extract one of our author's illustrative cases:—

"In September, 1848, I was requested to visit a servant girl who was suffering from violent pains in the bowels, and from constipation. The pain was incessant. From the experience which I had previously had in the symptoms of lead colic, I imagined her disorder to be such. She vomited constantly, and tossed uneasily in bed, groaning with pain. There was not much tenderness of the abdomen, at least not more than the vomiting and griping would explain. To ascertain the state of the bowels in respect to tenderness, it is as well to make pressure gently and gradually, judging the effect rather from the countenance of the patient than by what is said. After the bowels had been well moved, she became easier, and by taking small doses of Dover's powder, the pain was entirely removed. I explained to her the nature of the complaint, and she admitted having taken soft water from a lead cistern, but I did not examine the water. The pump belonging to the house was out of repair, and the water from it reported to be bad. In March, 1849, I was asked to visit her again. She was in the same condition, in the same pain, with similar vomiting and constipation, but she seemed more wretched-looking, more sallow, and more

emaciated. She had pain in the lower part of the back, and the gums were bordered with a deep-blue line. I told her that she had not been attending to my directions, and with reluctance she confessed that such was the case; however, she seemed indisposed to attribute her complaint to the reported cause, and looked somewhat dissatisfied with what I told her.

In July, 1849, she had another seizure. She had become sickly-looking, walked feebly, and was of a yellow complexion. There was the same colic, and the same constipation. When I spoke of lead, she smiled with a look of incredulity. I was really provoked at her want of belief, but seeing the miserable condition to which she was reduced, I felt obliged to give her my professional aid. I took great pains to instruct her on the subject, and lent her some books, and a pamphlet which I had published, to inform her further as to the complaint. I also took occasion to speak to the lady, who was the housekeeper, (it being the house of a widower,) but I met with little support. It was stated that others took the same water, without injury, and in the end, only a sort of cold assent was given to my injunctions. I shall, no doubt, surprise the reader with the continuance of my narrative, but I speak only the truth, which is sometimes more marvellous than fiction. On March 27th, 1850, she was ill again in the same way. She sent for me, being in great pain, and told me that she had done so with great reluctance—that she had been to consult another medical man since my last visit, who told her that her complaint originated in a diseased liver; and I scarcely wonder at his being deceived, by the sallowness of her complexion. I told her that I would not prescribe for her any more, unless she attended better to my instructions, which she promised to keep. After a few months, in September, 1850, she had again a bad attack of lead colic; and, during my attendance at the house, another servant became affected in the same way. The last person had not been long in the house, and indeed my former patient was the only servant who had been so. I think my patient was herself struck with the similarity of the complaint in her fellow-servant. I was resolved, on this occasion, to investigate the matter fully, and then require implicit obedience, or refuse further attendance; I accordingly furnished myself with some water, charged with sulphuretted hydrogen gas, and took it to the house, with a view to test the water which the family were in the habit of using. I perceived some hesitation about the bringing of the water, and was eventually told that there was none of the drinking water in the house. I insisted on being shown what was usually taken, and the source from which it was taken. At length the servant said—‘I see, Sir, it’s no further use deceiving you,’ and then she took me into the scullery, and from a tap drew some hot water. She assured me that this was the only water used, and that it was suffered to cool for drinking,—that it was used regularly for tea,—and that her master, a Greek gentleman, took it daily. On testing it, the water became of a dark-brown colour, almost like coffee. I found it was conveyed from a lead cistern into the boiler behind the fire-place, and from this boiler, by a lead pipe, into the scullery. I believed this time that I had made some impression, but in order to guard still further against

bad water, I directed her to live on a milk diet. Under this treatment she improved surprisingly, and recovered her usual looks, but she was unwilling to admit that it was owing to the disuse of the water. The family subsequently left the neighbourhood, but before she went she was well-looking, and free from disease.”

The principles of treatment seem to be, to avoid the cause, to expel the enemy, to allay pain, treat urgent symptoms, and to gain time. To fulfil the medical part, the author prefers croton oil, and afterwards opium. As antidotal remedies, he alludes favorably to diluted sulphuric acid, and mentions alum, but evidently depends more upon somewhat active purgation, sustaining the patient’s strength meanwhile. Of the subsequent treatment, we need only say that it is—what *all* judicious practice of physic must be—rationally eclectic.

Mr. Harrison has quite a talent for writing pleasingly. Few readers would anticipate an agreeable entertainment in perusing an essay on the “Poison of Lead;” but we can promise them, that though the subject sounds heavy, its treatment is light. A more fitting monitor for the public on a question which much concerns them, and a more pleasant and useful reminder for the profession, the author could scarcely have produced. We hope that many of our associates will read, and judge for themselves.

Elements of Health and Principles of Female Hygiène.

By E. J. TILT, M.D., Senior-Physician to the Farringdon General Dispensary and Lying-in Charity, and to the Paddington Dispensary for Diseases of Women and Children. London: Bohn.

In the *British and Foreign Medico-Chirurgical Quarterly Review* it was lately remarked that a treatise on female hygiène was much wanted; and all those engaged in general practice who have to contend daily with the ignorance and prejudices of women respecting themselves and their children will re-echo the assertion of our respected cotemporary.

Dr. Tilt has sought to fill up this desideratum; and we are anxious to be among the first to notice a book which originated in our columns. Two years ago Dr. Tilt inserted in this journal some highly interesting papers on the right management of women at the critical periods of life. These papers have suggested to the author the present work, of which we intend briefly to sketch the outline.

The work is divided into periods of seven years, and each period forms a chapter. Each chapter briefly notices the mental and moral development or decay, and the physical condition is treated with care. The food, clothing, exercise, and sleep, as regards each epoch, are passed in review; and the diseases to which women at each period are most liable is pointed out, as well as the most appropriate means of prevention. Every chapter is preceded and followed by tables showing the mortality of both sexes for each year successively, the mean duration of life, and its value for insurance purposes; calculations which derive importance from the fact of their having been made under the eye of Mr. Farr, of the Registrar-General's office.

Such is the outline of a work which combines a vast amount of information in a small compass, and of which we regret that our space will not allow us to give extracts; it is much required, and will, doubtless, ere long, become as popular as those of the lamented Dr. Coombe.

Perhaps no man is better calculated than Dr. Tilt to fill up this hiatus in medical literature; for few unite to the same extent, great opportunities of observation with sterling common-sense, a thorough love of his subject, and a lucid, correct, and lively style. We think the work will be found as useful to the practitioner as it is indispensable to those who are in any way connected with the education or responsibilities of women, for while, on the one hand, it is the best treatise on physical education with which we are acquainted, it also affords practitioners excellent advice respecting the prevention of nervous complaints, and in fact, of all the diseases to which women are amenable from the peculiarities of their formation and habits.

Provincial Medical & Surgical Journal.

WEDNESDAY, DECEMBER 8, 1852.

We lately printed the Medical Bill prepared by the Council of the Association in its amended shape, as corrected and sanctioned by the Committee appointed for that purpose at the Anniversary meeting at Oxford. The contemplated measure is now complete, as far as England is concerned; though of course the Committee still hold themselves at liberty to receive any

well-considered recommendation. For Scotland and Ireland the Association have never pretended to legislate, having all along maintained the principle that the profession in each part of our triple kingdom is best able to regulate its own affairs, and therefore best able to decide as to that portion of the Bill which more peculiarly affects its interests. Acting in this spirit, the Committee some time since appointed a deputation from their body, consisting of Mr. NUNNELEY and Mr. HASTINGS, to proceed to Edinburgh, and to confer there with the representatives of the Scotch Medical Corporations on the subject of the Draft Bill. This frank step was met in the most cordial manner, and has been attended, we rejoice to say, with the happiest results. The deputation of the Association were received with the greatest courtesy and kindness by the authorities of the Royal Colleges of Physicians and Surgeons of Edinburgh, and of the Faculty of Glasgow; and the representatives of the Scotch profession showed from the commencement of the negotiation that any objections they may have made to the measure were dictated by no factious motives; that they were not disposed—as we fear may be the case with some in England—to oppose every attempt for the amelioration of the profession which did not emanate from themselves,—that they were too generous to start unnecessary difficulties, and too liberal to deal in quibbles. With men actuated by so fair and honourable a spirit there was no difficulty in coming to a prompt and satisfactory conclusion.

The arrangement made by the gentlemen who formed the deputation, and which will doubtless be ratified by the Committee at their approaching meeting, was to the following effect:—The Council for Scotland is to be nominated according to a plan to be decided on by the Scotch profession; the examiners in that country are to be appointed by the Colleges, and not by the Council, as is to be the case in England; registration, which affords by the provisions of the Bill the only title to practice, is to take place in that country on the simple production of the licence of the Council. These points conceded, the Bill is such as will meet with the support of the Scotch profession; and there is not one of them which is not perfectly reasonable in itself, and which is not a matter altogether within their own cognizance. We may therefore conclude that the measure will shortly appear with the

alterations indicated above; and that the delicate question between the two sections of the profession north and south of the Tweed is set definitively at rest. We heartily congratulate the Association on this happy result of the conciliatory course adopted by the Committee; and we would observe that it is a circumstance which gives in many respects a new aspect to the Bill, and a new character to the support which it will receive in Parliament. It is no longer merely the measure of the Association; it is the measure of the medical profession throughout Great Britain, *minus* the few individuals who have hitherto avowed themselves hostile to it. It will be presented to the Legislature as the laborious and long-considered result of the united efforts of professional men on both sides of the Tweed. It is stamped with the approval of their practical experience, and moulded into working shape by their moderate counsels and wise concessions. With regard to those other bodies, whose voices have a right to be heard in the matter, we have only to say that measures are being taken to obtain the opinions of the Irish profession upon the Bill. Of course when these opinions have been fairly brought before the Committee, every desire will be manifested to defer to the just wishes and requirements of the Medical Corporations in the sister island.

We published a little time since some remarks on the Bill that had been forwarded to us by the Committee of the South-Western Branch. We then remarked, that several of the points complained of had been already remedied in the new edition of the measure, and we believe that no ultimate difficulty will be experienced in obtaining the unanimous support of the different Branches. The College of Physicians of London have throughout exhibited the most liberal feeling towards the Bill and its framers, and whenever they have been compelled to differ from the Committee, have stated their opinion fairly, and without reserve; we need hardly say, that the greatest desire is felt by those who in this matter represent the Association, to meet a body so influential and so justly esteemed as the College of Physicians, on every possible point. We believe that we are justified in saying, that there is now no portion of the Bill which presents any serious obstacle to our obtaining that which we desiderate so much—the approval and support of the College.

The College of Surgeons of England have not

hitherto expressed their opinions on the Bill in any decided way. A deputation, consisting of Mr. NUNNELEY, Mr. NOBLE, and Mr. BORTOMLEY, all Fellows of the College, has been appointed, to obtain an interview with the Council, and to lay the Bill before them. Such a meeting can hardly, in fairness, be refused; and it can hardly, either, fail to be productive of some decisive result. All that the Committee are anxious for, is to obtain the opinion of the College, *pro* or *con*, in the matter. If they are resolved to oppose the Bill, whether or no, let that at once be stated; if they will support it, conditionally, on certain alterations being made in it, let the Committee learn what those required alterations are. It has, indeed, been whispered, that the College are resolved—and have avowed their resolution—to oppose all Medical Reform, all future improvement. But such tactics can hardly succeed in the present day.

In conclusion we will only say, that if the Committee, backed as they are by the feelings of our powerful Association, have never hovered in their course, and never bated one jot of their resolution, even when support came only from our own ranks, they are not likely to do so now when they find themselves aided by our northern brethren, and sanctioned in their exertions by one of the great Medical Corporations; they will assuredly persevere in their course, and will, we doubt not, bring their labours to a triumphant conclusion.

Medical Intelligence.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 19th ultimo:—John Attwood, Australia; Francis Bramley Baker, Hampton Court; George Dransfield Brown, Croydon; Francis Russell Hall, Fulbourn, Cambridgeshire; Charles Rodney Huxley, Lisbon; Robert Thomas Ogden, Rochdale, Lancashire; Charles Schofield Richardson, Greenwich; George Sankey, Ashford, Kent; George Henry Thurston, Goswell Street; Arthur Umphelby, Ipswich, Suffolk; Robert Westcott, Spencer Street, Goswell Road; William Joseph Williams, Uffaulm, Devon.

The following gentlemen were admitted on the 26th ultimo:—John Ross Diamond, London; Charles Fluder, Lymington, Hants; Richard Savill Hanbury, Mirfield, Yorkshire; Philip Chas. Heyman, Axminster, Devon; David Johnston, Peterborough, Northamptonshire; York James Moore, Mount Street, Grosvenor Square; Elias Jones Roberts, Bangor, Carnarvonshire; Thomas Frederick Sanger, Alfriston, Sussex; Edmund Shaw, Thatcham, Berks.

THE FELLOWSHIP.—The following members were admitted to the Fellowship on the 21st October:—Alfred Baker, Birmingham; Christopher Hewetson Barnes, Notting Hill; Edwin Bartleet, Birmingham; Robert Shirley Belcher, Burton-on-Trent; Samuel Berry, Birmingham; Charles James Bleock, Warminster; Henry Blenkinsop, Warwick; Robert Bower, Rochdale; Peter Brendon, Highgate; Thomas F. G. Brownbill, Salford; Joseph Bullock, Congleton, Cheshire; John Cordy Burrows, Brighton; Cornelius Butler, Brentwood; William John Church, Bath; Edward Covey, Basingstoke; William Henry Covey, Wilton Street; William James Cronin, Queen's Town, Ireland; William Cross, Clifton; Frederick Davies, Upper Gower Street; George Edwardes, Wolverhampton; Joseph John Evans, Bristol; William Evans, R.N., Bath; George Payer, Barking, Essex; William Postescue, Smithfield Bars; John Frederick Foster, Hartley Wintney, Hants; Luther Owen Fox, Broughton, Hants; Robert Docksey Goodwin, Ashbourne, Derbyshire; John Fosse Harding, Myddelton Square; Hetman Charles Harris, Windsor Place, City Road; James Bower Harrison, Broughton, Manchester; John Bishop Haynes, Evesham, Worcestershire; Ed. Hickman, Southampton Place, Euston Square; George Leicester Hillas, Sydney Place, Brompton; Thomas Hodgson, Halifax; George Yeates Hunter, Margate; Edward Ingram, Boston, Lincolnshire; Abraham King, Bridgwater; George Lowdell, Brighton; Robert Merry, Hemel Hempstead, Herts; Thomas Middleton, Salford; John Muriel, Ely, Cambridgeshire; Daniel Noble, Manchester; Henry Peacock, Dockyard, Chatham; Houghton Perkins, Henrietta Street, Cavendish Square; John Ballard Pitt, Norwich; Robert James Pollock, Bath Place, Kensington; James Price, Brixton; John Pursell, Harleyford Place, Kennington; William Sudlow Roots, Kingston-on-Thames; John Rountree, Oldham; Arthur Brisley Rye, Banbury; Thomas Smith, Bow Lane; Frederick Theed, Rhyl, Flintshire; Frederick Hosken Tucker, Halifax; John Raggett Urwin, Claremont Place, North Brixton; Richard Wallace, Trafalgar Place West, Hackney Road; James Watkins, Falcon Square; Charles John Woods, Godmanchester; William Kelson Wright, Holland Place, North Brixton.

THE MIDWIFERY BOARD.—This Board, consisting of Mr. Luke, Senior Vice-President, (Chairman,) and Drs. Arthur Farre, Henry Oldham, and James Reid, met for the first time on the 24th ultimo, when the following gentlemen were admitted Licentiates in Midwifery of the Royal College of Surgeons:—John Armstrong, Manchester; William Henry Borham, Cambridge Terrace, Hyde Park; Robert William Cockerill, Symond's Inn; Francis Philip Cupiss, Eltham; George Earle, Beverley; Francis Russell Hall, Fulbourn; George Selwyn Morris, Sydenham Park; Samuel M. C. Anderson Smith, Kilburn; George Frederick Brutton Willing, Hampstead.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 17th ultimo:—Matthew Francis, Sunderland; Thomas Bryan Greenwood, Horslydown, Southwark; Charles Henry Payne, London; William Rookcroft, Wigan; John Shepherd, North Walsham; George Welford, Sunderland; Edwin Adolphus James Wilkinson, Northleach; William Young, South Shields.

APPOINTMENTS.

NAVAL.—Surgeons W. R. Dalton, to *Sidon*; R. Fulton, to *Furious*; and R. Clarke, to *Magicienne*. Assistant-Surgeon C. F. A. Courtney, to *Sidon*. Alex.

Baxter, M.D., (1836,) to the *Trafalgar*, 120, on the Mediterranean station; John Charlton, M.D., (1845,) to the *Magicienne*; Thomas Henry Lowry, M.D., (1845,) to the *Furious*; Robert Beith, M.D., (1852,) to the *Vulture*.

OBITUARY.

November 9th, at South Kirkby, near Pontefract, aged 46 years, Thomas Mitchelson Cole, Esq., M.R.C.S., and member of the Provincial Medical and Surgical Association, formerly residing at Kirkby Moorside, in the North Riding of Yorkshire.

On board the *Fox*, India Squadron, Mr. Morgan, the Assistant-Surgeon, from cholera.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

The Central Council of the Association beg to call the attention of those members whose subscriptions are in arrear to the following resolutions passed at the Anniversary Meeting, held at HULL, on the 7th and 8th of August, 1850:—

“But if any Member's subscription remain unpaid twelve months after it shall become due, the *Medical and Surgical Journal*, and other publications of the Society, shall be withheld from such Member till his arrears be paid; and when any Member has been in arrears of subscription for the space of *three years*, application shall be made for the same by the General Secretary, and if the arrears be not paid in *three months*, the name of that Member shall be omitted from the list of Subscribers; but this omission shall not be deemed, either in honour or equity, as releasing any Gentleman from the subscriptions owing during his Membership.”

Those gentlemen who have not yet paid their subscriptions for the CURRENT YEAR, or who are in ARREARS, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association at Worcester.

All post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

J. P. SHEPPARD.

Worcester, October 23, 1852.

Secretary.

TO CORRESPONDENTS.

As we already have more communications in hand than we shall be able to insert, we must beg our correspondents to forward them in future to DR. CORMACK, unless they require immediate attention.

Communications have been received from Mr. Colthurst, and Mr. Reid.

CASE OF STRANGULATED HERNIA.

By HENRY NORRIS, Esq.,

STRANGULATED HERNIA; OPERATION; RECOVERY; DEATH FROM INTemperance THREE MONTHS AFTER.

THOMAS BOON, aged 25, labourer, tall, well-formed, and rather muscular, was, on the 5th of June, 1852, suddenly seized with the following symptoms:—nausea and vomiting, accompanying a very painful tumour in the right inguinal region and corresponding side of the scrotum.

First visited at one A.M. on the 6th of June, when he gave the following account of himself:—Had been quite well the whole of the day previous, and had made a hearty supper as usual; had then felt sick, had vomited; had passed a natural stool, immediately on which the pain and tumour supervened, the pain being confined to the tumour. Further inquiry elicited the fact, that twelvemonths previously a horse had kicked him precisely over the painful spot, causing considerable inflammation of the testicle, and pain in the inguinal canal, which yielded to warm fomentations without surgical aid, the parts having been perfectly well ever since.

On examination I found the skin cool; pulse 70, regular, and firm, but not hard; tongue natural; countenance indicative of much suffering; no vomiting since the commencement of the attack; the right inguinal canal, and right side of the scrotum, were much distended, having precisely the form and feel of a swollen testicle, and inflamed spermatic cord. There was no impulse on coughing.

Suspicion pointed to strangulated hernia, but the taxis had not the slightest effect.—Ordered a warm bath, a full dose of calomel and opium, with Antim. Pot. Tart., in one-third grain doses every four hours.

10, A.M.—Matters just in the same state; pulse and countenance good; had slept a little; no vomiting, but nausea, from the medicine; taxis again failed.—To continue the mixture. Apply twelve leeches to the scrotum, and to have a warm bath every four hours, keeping a strict watch for any more urgent symptoms of strangulation.

June 7th.—Still the same. Consultation with Mr. Hey, of Bridport. Both of opinion that, without more decisive symptoms of strangulation, a continuance of the antiphlogistic treatment was proper.—Ordered venesection to thirty ounces, a strong purgative dose, large tepid-water enemata, and turpentine stupes over the abdomen, in case of any tenderness arising.

9th.—The patient continued in much the same state, and undergoing similar treatment, getting weaker, when stercoraceous vomiting occurred early in the morning, or during the night preceding. Assisted by Mr. Hey, I at once operated, and found the tumour to consist chiefly of omentum, with about eight inches of small intestine, both intensely congested. The hernia was easily returned, the patient bearing the operation well on the whole, but there was a considerable tendency to syncope.

10th.—Had a very restless night; symptoms of rapid asthenic peritonitis; pulse 150, and almost imperceptible; extremities cold; vomiting still stercoraceous; no movement of bowels.—Ordered nine leeches to the abdomen, turpentine stupes, and tolerably full doses of calomel and opium every three hours. In the evening the patient was worse in every respect; prostration complete; bowels not moved; vomiting continues.—Ordered an aperient pill every hour until the bowels act.

11th.—To my surprise the patient feels relieved in some measure; bowels have acted freely; vomiting not so incessant, but still in a state of collapse.—Ordered six drachms of port wine every hour; to be supported frequently with arrowroot, beef-tea, &c., &c. In the evening there was little improvement; still great tympanitis and vomiting; state of bowels such as to require Mist. Cretæ cum Opio every third hour.

12th.—Improvement continues; speaks cheerfully; wound dressed, looked well. Chalk mixture with nourishment to be continued.

13th.—Worse; alarming hæmatemesis and mœlena.—Ordered Spr. Terebinth., gtt. xv., tertius horis, with chalk mixture. To continue wine.

14th.—Improving; hæmatemesis, but not so frequent. To go on as before; wound dressed, edges have separated but they look healthy.

15th.—Better, and continued to progress until recovery was complete. At the proper time a well fitting truss was adjusted, and towards the latter part of August, he returned to his employment of carter to a neighbouring farmer, with the strictest caution on my part, to take every care of himself and particularly to avoid all excess in drinking. Being from home from the 26th to the 28th of August, I found the patient had died in my absence, under the following circumstances:—He had returned to his work on the 22nd, and the weather being very hot, he had drank freely of cider, more especially on the 26th, on which day he was seized with severe symptoms of entero-peritonitis, which, resisting all treatment, carried him off on the 28th.

I was fortunate enough to obtain a *post-mortem* examination of the abdomen, when I found sufficient evidence of intense peritonitis and enteritis. One band of false membrane amongst others, united that portion of the ileum which had protruded to the inner inguinal ring, and *this band was, as well as the adjoining bowel, intensely congested*. No strangulation existed at any part. At the commencement of the ileum, and adherent to it, was a gelatinous-looking mass as large as a hen's egg, which much resembled the white of an egg just commencing to coagulate under the influence of heat. I have no doubt the proximate cause of death was peritonitis, brought on by excess in cider drinking, during the period of unwonted exertion at harvest season, and I have deemed the case worthy of note, in several points, as for example:—

1st. The length of time that elapsed ere decided symptoms of strangulation appeared.

2nd. The prolonged period of collapse recovered from.

3rd. The accession of fatal inflammation on exposure to heat and intemperance, as affording a most useful lesson in regard to the extreme caution with which similar cases should be regarded, even long after a successful operation.

The whole case also affords high encouragement to practitioners of the *Nil Desperandum* school, which bid us often to hope against hope, and who directs us not only to be most careful in forming our plans for treatment, but also to follow them up when convinced they are right, even under circumstances the most discouraging.

Charmouth, October 7, 1852.

DEATH FROM THE FORMATION OF A FIBRINOUS CONCRETION IN THE HEART.

By W. GARSTANG, M.D., M.R.C.S.L., L.A.C., ETC.

On the 10th of February last I was requested to visit Mr. ———, a gentleman 64 years of age, who had been seized with erysipelas of the head and face. He was of a gouty diathesis, and had lived at all times freely. On some occasions he had shown signs of congestion of the liver, and even of ascites, but these attacks had always been removed by the usual treatment. On the present occasion these last-named symptoms were combined with the erysipelatous disorder. The erysipelas had given rise to much swelling of the head and face. The pulse was at 94, and moderately full; the tongue covered with a thick fur; bowels costive; motions deficient in bile; urine small in quantity, and of a high colour. I ordered, in the first instance, an aperient of calomel and colocynth; afterwards a mixture, containing antimony and nitrate of potass, every three hours. A cold lotion to be applied to the inflamed parts. On the following day the urine deposited lithes; the bowels acted well; the tongue was clean; the pulse at 90; and the inflammation abating. Favourable symptoms continued for a fortnight, and the patient became able to sit up for several hours during the day. His diet was improved, and he was allowed a small quantity of sherry at dinner. During the course of three weeks from this point there was not much change; the appetite was good; the digestive functions were performed well; the inflammation was gone, but the system did not seem to regain strength, and the heart's action was very feeble, the radial pulse being at 80, and weak. At the time now named (five weeks from the first attack,) the patient took a slight cold, and a mild repetition of the erysipelas, and of the hepatic derangement, appeared. These symptoms, however, were checked as speedily as before. The appetite returned, and digestion seemed to be easily accomplished; and yet, with all these favourable appearances, his strength failed, the action of the heart, and the respiratory movements gradually grew feebler, and at length, without any sign of pulmonary, cerebral, or abdominal

disease, these asthenic symptoms terminated slowly in death, just eleven weeks after the first commencement of the erysipelatous attack.

Post-mortem.—With the exception of a slight enlargement of the liver, we could find no organ exhibiting structural change. The lungs were perfectly healthy. Upon opening the heart, however, we discovered what, in my opinion, fully accounts for the gradual dissolution; a fibrinous mass filled both its right cavities, and sent up large and long branches into the pulmonary artery and its ramifications. The concretion was firm and white, and had an attachment to the walls of the heart.

Remarks.—I have but few remarks to make on this interesting case, and I should probably never have thought of publishing it at all, had not my attention been forcibly drawn during the last four months, to certain observations which have been made before the Medical Society of London, by Mr. B. W. Richardson, "On the Fibrinous Element of the Blood," and which have been reported in the columns of the *Lancet*. I find that in a paper read by Mr. Richardson, in November last, he thus observes:—"Lastly, in cases of asthenia, where fibrinous concretions exist in the heart, the very cessation of the act of life may be owing to their presence and gradual increase, the central organ of the circulation becoming literally choked by them.—(*Lancet*, 1851, vol. ii., p. 515.) In January, again, the same author briefly alluded to this subject, and produced a pathological specimen which strongly supported his views.—(*Lancet*, 1852, vol. i., p. 121.) And lastly, in the month of March, on exhibiting another heart in which a fibrinous clot was found, he gave more enlarged views on the matter, and threw out the idea, that during those diseases which are known to be attended with an abnormal quantity of fibrin in the blood, it may be, that some of the overplus of fibrin is deposited on the elevated structures of the moving heart, and he concluded by saying that:—"In all inflammatory cases marked by great superfibrination of the blood, and which end by what is called sinking, it would be interesting to learn how far similar concretions in the heart, may be concerned in bringing about the sinking state.—(*Lancet*, 1852, vol. i., p. 355.)

Now, without wishing to mention the many theoretical points which Mr. Richardson and other physiologists enter into with reference to the formation of fibrin, &c., &c., I cannot but observe that the case which I have related above, affords striking testimony as to the correctness of the opinions from which I have just quoted. My patient had suffered from erysipelas, a disease in which the blood is always superfibrinized, he sank in the most gradual manner, and the autopsy revealed no cause for the sinking, except (what was surely sufficient) a large fibrinous concretion in the heart.

Of course the narrative of a single case does not go far to establish a new opinion, but perhaps it may excite others to turn their attention to the same subject. I have been puzzled over and over again, at seeing patients gradually sink into death, after some slight disorder, with no evident disease that could account for such a

serious result. Now, if any explanation so simple as that given by Mr. Richardson, should prove, after further research, to account for some of these occurrences, a great step in the practice of medicine will certainly have been made. I shall look forward for further investigations on this subject with exceeding interest.

Dobcross, Paddleworth, near Manchester,
August, 1852.

ANOMALOUS CASE OF SCROFULOUS ABSCESS OF THE HEART.

By ROBERT RANKING, Esq., HASTINGS.

JAMES ASHENDEN, aged 39 years, of remarkably temperate and industrious habits, by occupation a gardener, after having complained of slight indisposition for ten days, which he attributed to having taken cold, and for which he had no medical assistance, was suddenly attacked on the morning of April 28th, 1831, at about eight o'clock, with the following symptoms:—viz., dyspnoea and most acute pain in the chest, referred especially to the region of the heart. The countenance exceedingly anxious and ghastly, having the appearance of a person suffering from extreme hæmorrhage, cheeks and lips perfectly blanched; extremities and the whole surface of the body cold and imbrued with profuse clammy sweat; eyes sunken; incapacity to lie down; pulse scarcely perceptible, about 70 beats in the minute. On inquiring into the circumstances of the attack, I learned that, feeling himself indisposed, he had, on the previous evening, taken a dose of Epsom salts, which had acted twice that morning; that he was in the act of stooping to pull some radishes, when he felt a degree of faintness come over him, attended with so much oppression at the chest, that he with great difficulty got home and threw himself upon his bed. I was sent for in great haste, his friends supposing that he was dying. My assistant who first saw him, directed sinapisms to be applied to the chest and feet, and ordered him a mixture with ether, ammonia, and mistura camphoræ, a dose to be taken every quarter of an hour.

Ten o'clock, A.M.—No improvement; state of collapse extreme.—Ordered to take hot brandy-and-water alternately with the mixture, and large flannels wrung out of very hot water to be applied to the arms, legs, and thighs.

Twelve o'clock.—Some degree of reaction; hands and body warmer; feet and legs still cold; pulse 108, exceedingly irregular; great oppression and disinclination to speak; complains of feeling sick.

Four P.M.—Called to him in great haste. Frequent vomiting; great prostration, amounting almost to syncope, after each fit of vomiting; pulse at the wrist of the same feeble character, and not synchronous with the pulsations of the heart.—To have carbonate of ammonia with lemon-juice, in a state of effervescence, every two hours.

Ten, P.M.—Much the same. Continue as before.

April 29th.—6 A.M.—Has passed a wretched night; vomiting incessantly; pain removed from the heart, but very acute over the right lobe of the liver. So much so that he declares the least pressure would be instant death.—To have a large blister applied over the pained part, and to take Hydrarg. Subm., gr. iij.; Pulv. Opii, gr. ss. quarta quaque horâ.

12 o'clock.—Sickness somewhat abated; oppression of chest much relieved; can now take a deep inspiration; pulse the same; extremities still cold.

Four, P.M.—Sickness returned with great violence; bowels have not acted. To have a purgative enema, and continue the calomel and opium.

Ten, P.M.—Sickness very urgent; pulse much more feeble and intermitting; pain returned with great violence; countenance extremely anxious and cadaverous. Has all along expressed a conviction that he is a dying man.—To continue the calomel and opium, and to have Arrowroot and brandy by teaspoonfuls, every ten minutes.

30th.—7 A.M.—Has slept at intervals during the night; says he has little or no pain anywhere; sickness still very urgent; exhaustion excessive; pulse scarcely perceptible, and so irregular as to be with difficulty counted; blistered surface covered with gangrenous patches, the size of half-a-crown.—To have Quin. Sulph., gr. iij.; Extr. Humuli, gr. iij., in a pill, every two hours.

Twelve, A.M.—Just before taking the first pill, he got the yolk of an egg beat up with wine, which remained on the stomach; has since taken four pills, and several articles of food, which have not been rejected; pulse not improved.—To take whatever he can fancy, provided it contains much nourishment in a small compass; and to have Quin. Sulph., gr. iv., secundâ quaque horâ.

Four, P.M.—Sickness much abated; pulse more regular and distinct; has retained his food.

Nine, P.M.—He is very much more comfortable; has no sickness, but complains that everything he takes is like pepper in his stomach.

May 1st.—7 A.M.—Much the same; an indifferent night; bowels constipated.—To have Hydrarg. Subm., gr. ij.; Ext. Coloc., gr. vj., in pil. ij., tertiâ quaque horâ donec alvus sit solut.

Two, P.M.—Bowels have not acted; abdomen painful and distended.—The enema to be repeated.

Ten, P.M.—No evacuation; no sickness; great pain and distension of abdomen to be prevented, and to take Ol. Croton, gtt. j., statim, and continue the quinine.

2nd.—7 A.M.—Has had two small evacuations from the bowels; complains of great oppression at the præcordia; pulse extremely weak; constant vomiting.

Ten, A.M.—Vomiting has again ceased, in other respects he is the same.—To continue the quinine and nourishment.

Four, P.M.—He is sinking. He continued to sink from this time, and died between one and two o'clock in the morning of May 3rd.

Sectio-cadaveris fourteen hours after death.—The

blood in the cuticular veins was fluid; the thoracic and abdominal viscera warm. *Thorax*: The pericardium was much thickened, and distended with a turbid yellowish fluid, in which were floating numerous shreds of coagulable lymph; the membrane was so firmly adherent to the heart at one part, that it could not be separated. The heart exhibited marks of excessive inflammation, being covered with flakes of coagulable lymph over its whole external surface, and upon examining the part where the pericardium was adherent, there was an abscess imbedded in its muscular structure, containing nearly two ounces of scrofulous matter; the right auricle and ventricle bore marks of inflammation internally, the vessels of the valves and lining membranes being highly injected. The liver, spleen, pancreas, and kidneys were in the same state of repletion. The gall-bladder was distended with bile, and its duct impervious. The mucous lining of the stomach and alimentary canal was in a state of inflammation throughout its whole extent.

Observations.—In reflecting on this case, and the morbid appearances discovered after death, I have sometimes been led almost to question how far I had done everything for the poor fellow that might have been done, or that the nature of the case required; whether blood-letting, either generally or locally, might have been adopted, with any prospect of relief, or with safety. This point was not overlooked at the time; but taking into consideration the extreme state of collapse with which the attack was ushered in, and which continued to its termination—a state very much resembling what we have since seen in the collapse of malignant cholera, I felt that any abstraction of blood would have increased the already frightful state of exhaustion, and hastened the fatal crisis. The sunken eye; the blanched, ghastly countenance; the indistinct, fluttering, irregular pulse; the cold clammy state of the whole surface of the body; and the fact, that the blistered part ran so rapidly into a gangrenous state, all evidenced so strongly the extremely depressed state of the vital powers, that there appeared to me no other hope of arresting the progress of the disease, but by getting the system under the influence of mercury as speedily as possible, and at the same time, supporting the vital powers by nutritious food, quinine, and diffusible stimuli.

Proceedings of Societies.

BATH AND BRISTOL BRANCH.

A SPECIAL general meeting of the BATH AND BRISTOL BRANCH of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, was held on Wednesday evening, November 24th, 1852, at the Royal Western Hotel, Bristol, for the purpose of receiving the report of the Council on the case *Bourn v. Cox*; and also for considering Dr. Swayne's motion in reference to a letter

published by Mr. John Barrett in a public newspaper, in relation to the same case.

Mr. NORMAN, of Bath, presided on the occasion. And there were also present from the Bath district—Drs. Davies and Tunstall; Messrs. Bagshawe, J. Barrett, Bartrum, Brace, Bush, Church, Crang, Flower, George, Ormond, and Soden. From the Bristol district—Drs. Budd, Davey, O'Brien, Swayne, and Symonds; Messrs. Burroughs, Bryant, Coe, Colthurst, Collins, Estlin, Godfrey, Green, Hinton, Lancaster, Leonard, Lucas, Macey, Mayor, Morgan, Prichard, Sawyer, Sleeman, Smerdon, and H. Swayne.

Mr. COLTHURST, Honorary Secretary of the Bristol Branch, read the notice convening the meeting, and the minutes of the last meeting.

Mr. E. L. BAGSHAWE, (Bath): Sir, I rise to ask,—As the whole matter was referred to the Council, what was the reason that some of the speeches at the last meeting were left out, and others abbreviated? Mr. Cox, Sir, has resigned, now he finds it convenient to do so. I was not aware that I was a member of the Association on the last occasion, having subscribed only the day before, but I came with Mr. Field, as one of the medical witnesses examined at the trial. I ask this question, and I am prepared to make other statements respecting this case.

Mr. WILLIAM BUSH, (Bath): I wish to ask one or two questions.

The PRESIDENT: We must dispose of Mr. Bagshawe's first.

Mr. BUSH: I think, Sir, the meeting will see the propriety of allowing me to ask one or two questions before Mr. Bagshawe is answered.

Mr. COLTHURST: Before answering Mr. Bagshawe, or hearing Mr. Bush, I beg, Sir, to append to the minutes of the last meeting which have been read, "that the question respecting Mr. John Barrett's letter, in reference to the case of *Bourn v. Cox*, published in a public newspaper, was adjourned till the next meeting." I omitted to read this by inadvertence just now.

Mr. BUSH: I do not think that Mr. Bagshawe will object to my questions being put first. The first I have to ask is, whether the Secretaries are provided with a professed reporter of this meeting.

Mr. COLTHURST: I beg to say that the sworn and accredited reporter of the Bankruptcy Court of this district is present for the purpose of taking the proceedings, and having provided the most acknowledged, and, I believe, the only publicly-recognised reporter of the district, I conceive I have discharged myself of any responsibility which may be considered to rest on the Branch or on the Secretaries.

Mr. BUSH: I wish to ask another question. I am sorry to make any allusion to the last meeting, but I think it necessary to inquire, whether the Secretaries have requested the reporter to take a verbatim report of all that takes place on the present occasion?

Mr. COLTHURST: Yes; he is instructed to take notes of all that occurs at the present meeting.

Mr. BUSH: I have to ask one more question. Is it the intention of the Secretaries that the report so made

by the professed reporter, is not to be printed in the *Journal* without the sanction of the Association?

MR. COLTHURST: If that question is put to me as one of the Secretaries, all I have to say is, that this is a branch of the General Association, and no report has yet been published by us in any paper not belonging to that body. The reporter was brought here officially on the last occasion, in consequence of the comments on Mr. Cox's conduct which appeared in the *Journal*, where the whole case was published, and in which the following remarks were made. Those remarks having been made, we were of opinion, that whatever occurred respecting this case in this branch, should be decidedly made public through the *Journal*. I will just read the last paragraph of the article which appeared in the *Journal* of October 13th:—"It is clear that the profession, and more particularly the Provincial Medical and Surgical Association, must either support Mr. Cox as an aggrieved member of their body, or they must affirm the truth of the verdict given by the Jury. The facts of the case were to have been brought before the Bath and Bristol Branch meeting of the Association on Thursday last; and we are quite sure, though we have not heard the result, that Mr. Cox will have received that treatment from them which his case demands." These are the Editorial remarks which appeared in the same number of the *Journal* which published Mr. Cox's own letter on the subject of his case, and which also stated that that letter did not free him in the slightest degree from the imputation which had been cast upon him of having acted most imprudently and improperly as a member of the Association. This being the case, the *Journal* called on the Bath and Bristol Branch either to free Mr. Cox, or to confirm the truth of the verdict which had been given against him. I conceive, then, that the report which was taken for us by the special reporter, was not taken for our special use as a branch, but generally for the information of the members of the Provincial Medical and Surgical Association, and as our ordinary proceedings are reported in the *Journal*, there was not the slightest reason to suppose that this matter should not appear in the *Journal* also. For my own part, unless it were otherwise ruled, I should conceive it my duty to this branch, and to the Association generally, to transmit the report of whatever transpires here to Worcester, for publication in the *Journal*.

MR. JOHN BARRETT (Bath): Sir, with Mr. Bagshawe's permission, I say that this is no answer to Mr. Bush's question. There has been no charge brought against the Secretaries respecting the report which has been published; but the question refers to the report of the present meeting, and the answer is, that the report taken by the reporter is to be published without the sanction of this branch.

MR. COLTHURST: I think the Secretary has answered very distinctly that the report is to be published in the *Journal*, unless the gentlemen present refuse that it should be, or decline to sanction such a course. I have said this previously, and I have to state distinctly, that the Secretaries will consider it their duty to publish the

report in the *Journal* unless the gentlemen present request that it should not be so.

MR. BARRETT: Perhaps I may be allowed to ask,—Is the leading article in the *Journal* authoritative? Does it express the opinion of the Association? Does it come with the authority of the Association? Or is it to be considered as the article of the Editor only?

THE PRESIDENT: The article is the production of the Editor of the *Journal* alone, and goes for no more.

MR. COLTHURST: The only rule of the Association that I am aware of, applicable to the publications, is this,—“That the Council consist of a President and

members, to be selected from the principal provincial towns. The Council, with whom must rest the chief responsibility of publication, to have full power of deciding on all papers transmitted, and the consent of three of its members must be obtained before any paper can be published.” This is the only rule of the Association with regard to publications; but since its adoption the *Journal* has been established, and therefore there are no rules at all applicable to our fortnightly publication. It is, however, considered that, as the Editor of the *Journal* was appointed by the Association, he is responsible to the Association and not to the Council.

MR. J. BARRETT: I then understand, that the editorial articles in the *Journal* do not appear on the authority of the Council, but merely as the articles in any other journal. That is the point on which I wish to be certain.

MR. E. L. BAGSHAWE: I wish to ask why the report of the last meeting was published, while the case of Mr. Cox was *sub judice*, and why some speeches were left out altogether in that report, and some others were curtailed?

MR. COLTHURST: The report of the proceedings at the last meeting was sent to the *Journal* to set forth the facts of the case as far as they were gone into by this branch, and for the steps which were taken to procure the report of the last meeting, the responsibility so far rests with myself. The reporter was requested to give a general outline of the facts of the case as far as they came before the meeting, with the view of putting before the Association generally, the opinions which were expressed by this branch. He was not desired to give all that transpired, *tot dem verbis*; and therefore, after the meeting he transmitted to me the report, which was sent to the *Journal* without the slightest alteration or addition. I am, literally speaking, incorrect in this statement, inasmuch as the reporter left a blank in two instances, of part of a word, which I supplied. It was a technical term ending, as the reporter stated to me, in “*mosis*,” and of which he was not sure; and I supplied the blanks he had left, by rendering the word “*phimosis*,” (Laughter.) With this exception, the manuscript was forwarded by me to the *Journal* in the precise state in which it reached my hands. (Hear, hear.) Since the last meeting, and before the Council meeting was held, one of the members of this branch applied to me, and asked the same question which has been put by Mr. Bagshawe. He wished to know why the

speech of Dr. Budd only on one view taken of Mr. Cox's case, had been reported. I therefore, applied to the reporter to know his reason for the omission, and and to ascertain the precise sequence in which each individual spoke. He gave me this list to show why he had concluded his report with the statement, "that Mr. Godfrey, disagreeing with the view taken by the last speaker [Dr. Budd], moved 'That the whole subject with regard to Mr. Cox be referred to the Council, with a request to them to report on it to the next quarterly meeting.' Dr. Symonds seconded this proposition, which, after a lengthened discussion, was carried in the affirmative." He stated, Sir, to me, from his note-book, that after Dr. Budd's speech, which was reported, Mr. Godfrey moved his resolution, and was followed by Mr. Norman (the President.) Dr. Symonds seconded Mr. Godfrey's motion; Dr. Budd spoke again; Mr. Godfrey spoke again; Dr. Budd spoke again (laughter); Dr. Symonds spoke again; Dr. O'Brien spoke; Mr. John Barrett spoke; Mr. Coe made an observation; Dr. Davies spoke; the President (Mr. Norman) spoke; Mr. Green spoke; Dr. Budd spoke again; Mr. Godfrey spoke again (laughter); Mr. Coe made his speech; Mr. Godfrey spoke again; Mr. Coe spoke again (laughter); Mr. Godfrey spoke again; Mr. Coe spoke again (renewed laughter); Dr. Symonds spoke again; the President put the resolution; Mr. Stone spoke; Mr. Cox spoke; Dr. Tunstall spoke; Mr. Godfrey spoke again (laughter); Dr. Budd spoke again (renewed laughter); Mr. Macey spoke; Mr. Soden spoke; Mr. Coe spoke again (laughter); the Secretary read the 22nd rule of the Association; and the resolution was then put and carried. (Applause and laughter.) The reporter stated to me also, that upon looking over his notes he considered he had given the substance of all that transpired, and that it was far better to conclude as he did, rather than to put in all the interlocutory speeches and observations which were made after the addresses which he had given in full. That is so far my answer to the gentleman who applied to me. The same question has been put by Mr. Cox, and is now repeated by Mr. Bagshawe, and I have only the same answer to make to them. I may say, however, that in consequence of the representations which have been made to me, I have requested the reporter to make a verbatim report of all that transpires at the present meeting, and to transmit it to the Secretaries, so that the whole of the remarks which may be made, may appear in print, if it should be the pleasure of the Association. (Applause.)

The PRESIDENT: I may say, that as it appears from the list that has been read that some of the members were allowed to speak two or three times on the last occasion. I think it could not have been two or three speeches on the point that these gentlemen made. It must have been asking questions or making observations that brought them up so often. However, it will be very wholesome if we take care this evening that no one speaks more than once. (Hear, hear.)

Mr. BAGSHAWE: I think my question has not been answered. The matter of Mr. Cox was referred to the

Council at the last meeting, at which Mr. Cox, as well as Mr. John Barrett made use of certain names which had nothing to do with the case. I attended there as a stranger on that occasion; and I heard Mr. Cox refer to the Jury before whom the case was tried. Now, he might have stated that two of the Jury were retired medical men, that one of them was a major in the army, another a great brewer, and that another was a large landholder; all residing out of the city. He also related a conversation stated to have taken place between Mr. Harries and Mr. Barter, which Mr. Harries denies; and Mr. John Barrett stated that he had a conversation with a witness at the trial named Biggs, which Mr. Biggs also denies.

The PRESIDENT: I should be loath to interfere with Mr. Bagshawe in asking any question; but it seems to me that we have nothing before us till the report of the Council is read. (Hear, hear.)

Mr. JOHN BARRETT: May I not correct the remarks which have been made by Mr. Bagshawe respecting me?

The PRESIDENT: I think not now. We have been sitting here for half an hour, and nothing has been done but conversation. I think if we read the report of the Council there will be something before the meeting. The Secretary, I understand, has no further answer to give to Mr. Bagshawe.

Mr. COLTHURST then read the following

Report of the Council re Bourn v. Cox.

Gentlemen,—Your resolution of the 27th October, in which you referred the whole subject with regard to Mr. Cox to the Council for its examination, having left it open to them to report thereon either to the next quarterly meeting, or to another meeting to be specially convened, your Council, mindful of your great anxiety to learn the whole truth before consenting to the justice of the stigma cast upon a brother member, have lost no time in instituting the inquiry directed by you, and have called you together this evening to hear the result.

Your Council would premise that, with the view of carrying out your instructions "to examine the whole subject with regard to Mr. Cox," they determined to hold their meeting in Bath, the residence of Mr. Cox and the several witnesses; and accordingly issued a note to each individual who was supposed to be able to give information on the subject, requesting their attendance at the Council meeting to be held on Nov. 12th, at the Bath General Hospital, whilst to Mr. Cox himself was sent the following note:—

"41, Gay Street, Nov. 8, 1852.

"Sir,—On behalf of the Council of the Bath and Bristol Branch of the Provincial Medical and Surgical Association, I have to request you to attend their meeting at the Bath General Hospital on Friday evening next, at half-past six precisely, with Mr. Lawrence, your books, and such other evidence bearing on the professional facts of the case, 'Bourn v. Cox,' as you may please to adduce.

"The court being a 'court of honor,' it will be proposed that Mrs. Bourn, Messrs. Gibbs, Cousins, Topp, and Harries be examined, and state the facts relating to the professional part of the case within their knowledge; and that Messrs. Skeate, Field, Bagshawe, and Bartrum, attend, that, if it be desired, they may reiterate the opinions given by them before the County Court.

"I think it but right to let you know that if you please the reporter of the *Bath Journal* can supply you with a verbatim report of the proceedings on that trial.

"I remain, Sir, yours obediently,

"J. S. BARTNUM.

"Honorary Secretary Bath Branch.

"W. A. Cox, Esq."

Pursuant to the notice, the meeting was held, and the following members of your Council attended, viz., Geo. Norman, Esq., President, in the chair; Messrs. Symonds, M.D., Ormond, Morgan, Estlin, Budd, M.D., Flower, Colthurst, Davies, M.D., Church, Clark, Bartrum, Hodges, M.D., Swayne, M.D., George, Smerdon, and John Soden.

Before, however, your Council could enter on its business Mr. Cox stepped forward, and presented the following letter to the President:—

"To George Norman, Esq., President of the Bath and Bristol Branch of Provincial Medical and Surgical Association.

"Sir,—The Council have determined to open my case anew, and to call before it witnesses whose sole wish is to condemn and injure me, and who would not before such a tribunal be under the restraints which attend an examination in a Court of Law, and might therefore give unbridled license to their ill feeling, has taken a course which is beyond its jurisdiction, and is manifestly unjust to myself. I therefore avail myself of this mode of offering a few observations upon its proceedings in the matter.

"It will be remembered that the case has been fully investigated *as against me* before a Court of Law; and that there, upon the statements of medical men, I was accused of having trumped up a bill, of having set forth such a combination of diseases as had not been known to co-exist, and as could not be cured in the time; in fact, of having wilfully and deliberately lied in this bill for the most execrable purposes. It will also be remembered that those statements of the medical men, although so unanimously and unhesitatingly made at the trial, were abandoned as untenable and incorrect within a few days afterwards; that after openly publicly branding me as the designing concoctor of an ignorant and lying bill, it privately admitted that the ignorance and inaccuracy of statement lay in the testimony which had been given upon oath. This was the position of the case when it was brought before the Society.

"At the first meeting upon the subject I opened the matter as fully as possible, and exposed my book to examination, not because I thought that I was bound so to submit myself, for I conceive I might have taken as of right much higher ground; but because I was above disguise, and wished so to act. I then took up the adverse medical testimony given at the trial, analysing, examining, and refuting it in every point, except that as to the amount of charge. This I did in the presence of three of the adverse medical witnesses, and not one of them, nor any other member in attendance, advanced a single word in defence or support of the opinions so confidently given at the trial, that the diseases could not coexist, could not be cured in the time stated, and that the treatment described was improper. Before those unacquainted with the principles of our profession, the adverse medical witnesses had been loud and confident, but before a meeting of its members they were dumb. Three-fourths of the case thus fell to the ground. Here, then, the Society had before it a member who had erred in judgment, and had candidly acknowledged that error, but who, by false testimony, had been untruly held forth to the world as guilty of wilful and deliberate lying and deceit, and of incapacity in his profession; and it is worthy of much consideration by the Society, that the previous conduct

of this member was not only unchallenged, but acknowledged to be honourable and honest by his opponents. Did not justice and conscience, then, demand of the meeting that they should free his character from those false aspersions, and so far as the power of the Society extended, nullify the effect of the publication and circulation of those false statements. Was I only an offending party, or a greatly injured one also? Was my offence to be punished, and my injuries to remain unmitigated? Let us see.

"Some of the medical witnesses at the trial have, to my knowledge, been industriously employed, in and out of the town, in endeavouring to raise a party against me not to institute a fair investigation, with a view to elicit truth, but to carry out their predetermination to drive me out of practice here, if possible. And these efforts have been continued in the meetings of the Society, for (unfortunately) the Bath Secretary of the Society is one of the most active in these attempts, and the case has, in fact, been thus drawn and driven to this point, that I cannot be cleared without leaving a great amount of odium upon him and others connected with him. For this state of things I am not accountable, neither ought I to suffer, but I find it is intended that I shall be made to bear the consequences, so far as the Society is concerned.

"As a proof of this, open to the observation of all, I may notice that a report taken of the proceedings of the meeting, which was expressly authorised as the confidential report of the Association, is in violation of the implied faith that it shall therefore be used for the purposes of the Society only, inserted without authority, in a garbled shape, in the *Provincial Medical and Surgical Journal*, portions favourable to myself, and others unfavourable to Mr. Bartrum, in the strongest and most decided terms, being omitted.

"For instance, there is an entire omission of Mr. Norman's remarks on the merits of the case, in which he pointedly showed the inaccuracy of the statements of the adverse medical witnesses, and quoted authorities in support of his views. Again, in the omission of the observations of Dr. Davis, when citing his experience in the hospitals of Paris, as having frequently met with such a combination of diseases as had been described by me; and who, as he said, could account for the statements of the medical witnesses only upon the supposition that they had forgotten what they must have often witnessed. And the entire omission of the speech of Mr. Godfrey, which was a complete answer, in my favor, to the specious observations of Dr. Budd.

"A further proof of the same kind is, that a notice was inserted in the *Bristol Gazette*, published the Thursday after the meeting, promising a report or further particulars.

"A third proof I may mention, is the notice I have received from the Bath Secretary, to attend this meeting, in which he informs me it will be proposed to examine some witnesses at the trial others not then called, and amongst the latter, in outrage of all the decencies of society, the attorney who was employed against me at that trial.

"But I feel that these indications, strong as they are, are yet not equal to that hostility which is described to me as existing in the minds of some of the Society, and of which, as I have already stated, it is intended I should bear the consequences.

"However, the adoption by the Council of this motion, shows their intention to travel beyond the question committed to them by the Society, and advises me to resign my membership in the Society, and I therefore here resign that membership, and so frustrate the hostile desire of the authors of the motion. I thus quit the Society, and although I cannot obtain from it that benefit and assistance I might have expected, yet I leave it with the conviction that not one of the charges which I have denied and rebutted, both in person and

by this letter, has an abiding place in the mind of any member who is free from the bias of passion in the matter.

"One duty remains—a pleasing one amongst all this unfortunate strife and turmoil—to thank those gentlemen in the Society who have distinguished between error in judgment and immorality, between a precipitate step and a deliberate fraud, and have had the generosity and courage to express their convictions in behalf of one whom some others would have hallooed on to destruction, and from my heart I thank them.

"I am, Sir, your obedient servant,

"W. A. COX.

"54, New King Street,

"November 12, 1852."

Whereupon your Council (having heard the letter re-read by the Secretary, and duly considered it, paragraph by paragraph) unanimously agreed that although the witnesses were in attendance, it would not be desirable to examine them in the absence of the accused. They moreover resolved that (indifferent as they were to the insinuations contained in Mr. Cox's letter as to their own motives and intentions,) they could not separate without distinctly repudiating his accusations against their Secretaries, and expressing their opinion that the whole tone and character of his letter were such as to dispel any regret they might otherwise have felt at Mr. Cox thus evading an investigation which (though of a more searching character than he probably expected at the time he accepted the reference to their tribunal,) was intended to ascertain (as shown by the resolution of your meeting of Oct. 27th,) whether Mr. Cox could be cleared from the stigma already laid upon him by the verdict of the Bath County Court. The letter, with its many unfounded and malicious assertions, has left upon their minds a more painful impression with regard to Mr. Cox's conduct in the whole transaction than anything hitherto brought to their notice. (Much applause.)

The PRESIDENT: Does any one move the adoption of the report? If it is moved and seconded, we shall have it before us to discuss.

Mr. GODFREY (Bristol): To save time, Sir, I will move the adoption of the report *pro formâ*.

Mr. CRANG (Timsbury): I will second that.

The PRESIDENT: Mr. Crang is a member of the Council, I believe, and this is the report of the Council which he has seconded.

Mr. COE (Bristol): I shall be most happy, Sir, to second the adoption of the report. I do not, however, wish to make any observations at present, and I suppose I may speak afterwards.

The PRESIDENT: Certainly,

Mr. BUSH: If I understood rightly just now, Sir, each individual was only to speak once, except the proposer of a resolution. I wish to know if that is so, or whether we are to give the seconder the right to be heard again.

The PRESIDENT: It is usual, I believe, to allow the mover and seconder of a resolution to speak twice.

Mr. BRYANT (Bristol): I beg to second the motion then, Sir, if Mr. Coe wishes to speak afterwards, and there is any doubt about his right.

The PRESIDENT: Upon recollection, I think that is the proper course. The proposer generally assigns

some reasons in support of his motion, and he is entitled to reply to any objections which may be urged against it; but not the seconder.

Mr. J. S. BARTRUM (Secretary to the Bath Branch): After the report which has been read, Sir, I feel it due to the Association to lay a plain statement of facts as regards the Bath Secretary before the meeting. I stand here utterly as unconscious of having acted towards Mr. Cox with any hostile feeling as an unborn babe. I went into the witness-box to say what I thought of the case; and I have nothing now to add or to alter in the evidence I then gave. In relation to the Bristol meeting, I consulted yourself, Sir, as the President of the branch; Mr. Clark, the President-Elect; and Dr. Symonds, a past President; and you were unanimously of opinion that the case should be investigated. I accordingly, in my official capacity, without fear, favour, or affection, endeavoured to obtain such evidence as would put the whole matter before the Council, and that they might thereby come to correct judgment upon it. With this view I procured the statement made by the mother of the young man, and also his own written statement (which under the circumstances would be received as evidence in the Court of Chancery) that eighteen mixtures alone were supplied to him, and that he only saw Mr. Cox twelve times.

Dr. DAVIES (Bath): Ought we to go into this?

The PRESIDENT: I think Mr. Bartrum is now stating evidence which the Council would not have heard.

Mr. BARTRUM: Very well, Sir, I will of course withdraw it. I have merely alluded to the matter to bear myself out that my only reason for proceeding as I did was that the subject should be fully investigated; and that Mr. Cox should have the fairest opportunity possible of knowing the line of investigation that was to be pursued, I wrote the note to him which you have heard to-day; so that there should not be the shadow of suspicion of treating him unjustly. With regard to odium and hostility towards Mr. Cox, it is as absent from my mind as I believe it possible to be. I repudiate it altogether as towards him and every other member of the Association. My course has been to act with simple, plain, and unmitigated justice, and I repudiate any personal feeling whatever in the matter. Having said so much, Sir, I, with confidence, leave the case in the hands of the Association. (Applause.)

Mr. WILLIAM BUSH (Bath): Mr. President, I wish to make a few remarks on the case. I am not responsible for this letter of Mr. Cox's; but still I cannot conceive that the Council, or rather this Association, will arrive at so harsh a resolution as is indicated in that report, without hearing what may be offered in defence of Mr. Cox. It is my intention, Sir, to go over the several clauses in Mr. Cox's letter to the Association; but, first of all, I may state that that letter was written, to my knowledge, in a very hurried manner; and I ought also to say that I saw it in a rough way some twenty or four and twenty hours before it was handed in to you. There were many

parts of that letter to which I objected, and which I regret should have been inserted; but, Sir, taking it as a whole with one or two exceptions—one, for instance, relating to the Council of the Association—I cannot see any very great objection to it. I will, if you please, Sir—and I hope I shall not take up too much time in going over the various subjects—take clause number one in Mr. Cox's letter, which is this,—“The Council having determined to open my case anew, and to call before it witnesses whose sole wish is to condemn and injure me, and who would not, before such a tribunal, be under the restraints which attend an examination in a court of law, and might, therefore, give unbridled license to their ill feeling, has taken a course which is beyond its jurisdiction, and is manifestly unjust to myself. I therefore avail myself of this mode of offering a few observations upon its proceedings in the matter.” Mr. Cox laboured under the impression, as I did myself, when that letter was forwarded by him to Mr. Bartrum, that the Council had consented to call additional witnesses before them; and the letter which was read by Mr. Colthurst just now (written by Mr. Bartrum), appears at first sight to confirm that opinion. I should like to ask, for I am not positive on the point, whether the Council did not have a meeting very shortly after the last meeting of the Association, and before the meeting at Bath?

The PRESIDENT: No. Certainly not before the meeting at the Bath General Hospital.

Mr. BUSH: Then I am bound to say that nothing was adduced at the last meeting of the Association which would empower the Secretaries to call additional evidence against Mr. Cox. It was then understood that the whole case should be gone into. (Loud cries of “Hear, hear.”) I say it was then understood that the whole case should be considered as regarded the evidence which had been already given against Mr. Cox, with Mr. Cox's books, which he produced at that meeting. Nothing was said of calling additional evidence at your Council meeting.

The PRESIDENT: When that meeting was about to be held, the Bath Secretary spoke to me, and Dr. Symonds, and Mr. Clark, and we were all of opinion that it was sent to us as a court of inquiry. But I should also say this, that Mr. Bartrum was quite at liberty to procure other witnesses, and it would be for the Council to say whether they would receive their evidence. The impression on my mind is that the Council would not, but there was nothing to prevent the Secretaries from summoning additional witnesses if they thought proper.

Mr. BUSH: May I ask,—Did you authorise the Secretaries to summon additional witnesses?

The PRESIDENT: No.

Mr. BUSH: Then the onus must rest upon the Secretaries themselves.

Mr. COLTHURST: Without wishing to interrupt Mr. Bush, I think it will save time if Mr. Godfrey's original resolution be read; I have already read it from the minutes, and have brought with me the original resolution as it was handed to me, which I will now read—

“That the whole subject” (it does not specify any part as to evidence) but “that the whole subject with regard to Mr. Cox be referred to the Council for its examination and report to the next quarterly meeting, or to another meeting specially convened.”

Mr. BUSH: I admit that was so; but I don't think the meeting consented to allow one of those parties to be subpoenaed who was actually at the trial, to give evidence against Mr. Cox, but was not called. Mr. Cousins is the individual I allude to; and there was some objection, I understand, to him, as being only hearsay evidence. Now, why this individual should be allowed to give evidence before the Council when the solicitor or barrister who conducted the case against Mr. Cox refused to call him—why he should be heard, I cannot understand.

Mr. ORMOND (Bath): Mr. Bush is under a mistake, there was no evidence heard by the Council.

Mr. BUSH: I am supposing that the object of the Council had been to hear evidence, and that it was determined by them to hear these witnesses.

The PRESIDENT: Certainly not.

Mr. BUSH: Those, Sir, were my opinions, and they were also Mr. Cox's opinions, as appears from the letter which he has forwarded to you. It is not for me to decide whether they are right or wrong. We also understood that Mrs. Betty Bourn was to be examined. Now, Mrs. Betty Bourn had said her say at the trial, and it was difficult to see why she should be called again, or the plaintiff's solicitor, why he should be called. I am certainly of opinion, though I may be wrong, that the Council had already before them sufficient evidence to enable them to come to a correct decision. I now come to the second clause of Mr. Cox's letter, which is this:—“It will be remembered that the case has been fully investigated as against me in a Court of law; and that there, upon the statements of medical men, I was accused of having trumped up a bill, of having set forth such a combination of diseases as had not been known to co-exist, and as could not be cured in the time; in fact, of having wilfully and deliberately lied in this bill for the most execrable purposes. It will also be remembered that those statements of the medical men, although so unanimously and unhesitatingly made at the trial, were abandoned as untenable and incorrect within a few days afterwards; that after openly, publicly branding me as the designing concocter of an ignorant and lying bill, it privately admitted that the ignorance and inaccuracy of statement lay in the testimony which had been given upon oath. This was the position of the case when it was brought before the Association.” Sir, it is reported, whether truly or not I will not say, that the Secretary, Mr. John Bartrum—and I leave him to contradict the statement if it is unfounded—that Mr. John Bartrum told you, Sir, a short time after the verdict, “Oh! with regard to the co-existence of syphilis and gonorrhoea, we give up that point.” I call on Mr. Bartrum now to admit or deny the correctness of that report.

Mr. BARTRUM: I deny that I had any conversation with Mr. Norman upon the subject.

Mr. BUSH: Well, then, I will ask the President.

The PRESIDENT: I have no recollection whatever upon the subject.

Mr. BUSH: Well, I must give up that point. I can only say that what I have stated was currently reported. Mr. Bartrum, at all events, will remember a conversation which he had with me in Old Bond Street, in which he said that it was only Mr. Topp, who was not a medical man, who had stated that the two diseases could not co-exist.

Mr. BARTRUM: Sir, is this meeting held for a cross-examination of me, or is it for the purpose of examining the report of the Council?

The PRESIDENT: I think, Mr. Bush, it will be better for you to go on without asking questions. I take it that if you state what you have to say in your address to me, the meeting will pass those observations as things you understood; but if Mr. Bartrum or any other gentleman to whom you may allude rises to interrupt you in the way of explanation, I think they have a right to do so.

Mr. BARTRUM: Mr. Bush wishes me to say—

The PRESIDENT: No, he does not wish you to say anything; but he says that he saw you in Old Bond Street, and that you said to him that it was only Mr. Topp, who was not a medical man, who had said that the two diseases could not coexist.

Mr. BARTRUM: I did so express myself.

Mr. BUSH: In reply to that I will refer to the report of the trial. I cannot lay my hand on the passage at this moment. (After searching for a short time Mr. Bush proceeded.) I have it now, Sir. I am quoting from the report of the Judge's summing up, which appeared in the *Bath and Cheltenham Gazette*. "As one witness after another was called," said the Judge, "they all agreed that they did not believe that such a case ever existed and was treated in the same way. Their evidence, the Jury would see, took a duplex form. They did not believe that the diseases which were specified upon the face of the bill ever could co-exist in the same patient; and that, supposing the effects, and nature, and symptoms of the patient's case to be truly described, then they maintained that the treatment was incredible."

Mr. COLTHURST: I beg, Sir, to interrupt Mr. Bush by stating that I have seen two Bath papers, containing two distinct versions of the trial; and in consequence of that Mr. Cox was informed that he might have from the reporter of the *Bath Journal* a verbatim copy of the trial, so as to show whether these statements were actually made by all the medical witnesses. Mr. Cox has declined to take the opportunity which was thus afforded him; and I do think that it is occupying the time of this meeting most unnecessarily in opening a question which Mr. Cox has had full opportunity of bringing before the Council. Having been referred to this reporter, it was open to Mr. Cox to accept or to refuse to avail himself of his services. He has had the opportunity to rebut any evidence which he may conceive to be incorrect, and to prove the correctness of the evidence of his own witnesses; but having refused

thus to meet the question before the tribunal to which it was referred, I think it unnecessary, and I will say unjust, to open the question again here. As regards the Secretaries of this branch, Sir, one of them certainly has had nothing whatever to do with Mr. Cox's case before it came under the notice of this branch; and the other, I am sure has not the slightest objection to meet the question which has been raised respecting him. In fact, Sir, as I have already stated, the Bath Secretary has not the slightest personal feeling in the matter, and, having referred Mr. Cox to the individual who is prepared to give him a verbatim report of the trial, I do not think we ought to refer to any more newspaper reports here. There are two papers in Bath containing reports of the trial, one is the *Bath Gazette*, and the other the *Bath Journal*; and as I before said, they both contain distinct versions.

Mr. BUSH: After what Mr. Colthurst has stated, I will not go through the clauses of Mr. Cox's letter seriatim; but I will make a few remarks generally upon the case. And, first of all, I would ask whether Mr. Cox had not just grounds for withdrawing from the Association?

Mr. COE: Sir, I rise to a point of order. The question before us is as to the report of the Council, whether we shall receive it or not; and I submit that Mr. Bush has a right to argue against its reception and nothing else.

Mr. BUSH: It is my intention to move an amendment to the original resolution.

The PRESIDENT: I think Mr. Bush, if he objects to the report and means to move an amendment, has a right to go into the case of Mr. Cox, not fully, perhaps, but into such parts as he thinks fit.

Mr. BUSH: I will cut it as short as possible, Sir, (laughter). I ask, first, whether Mr. Cox had not just grounds for withdrawing from the Association; and, secondly, whether he had not also grounds for the remarks which he has made on the Secretary of the Association? I have already stated that Mr. Cox laboured under the impression that the Council were about to call fresh evidence against him, and for that reason he withdrew. With regard to the Secretary, I have told you that I am not answerable for Mr. Cox's remarks; but he labours under the impression that the Bath Secretary—

Dr. TUNSTALL (Bath): Sir, I rise to order. We are not met to hear the accusations of Mr. Bush and Mr. Cox against our Secretary. Let Mr. Bush speak to his amendment. We are not here to discuss the conduct of Mr. Bartrum, but to discuss the report of the Council.

The PRESIDENT: I must say that Mr. Bush is in order. The Council, in their report, have stated that Mr. Cox's letter has given them a worse impression of the case than anything hitherto brought to their notice; and, therefore, I think Mr. Bush is justified in showing the circumstances under which the letter was written.

Dr. TUNSTALL: But, Sir, is he in order in attacking our Secretary?

Mr. BARTRUM: I am quite prepared to bear the attack.

The PRESIDENT: If Mr. Bush, instead of asking questions, were to assume that the facts were so and so, then we should get on; and then let some one contradict him afterwards.

Mr. BUSH: I will endeavour to do so. First of all, Sir, it is reported that Mr. Bartrum had a conversation with a gentleman in the streets of Bath, in which he stated that the rumours about Mr. Cox were not half so bad as the facts really were.

The PRESIDENT: That is asking for a reply, Mr. Bush.

Mr. Bartrum rose, but

Mr. BUSH proceeded: Secondly, the evidence given against him he conceives was of the most damnatory character.

Mr. BAGSHAW: What was that last word?

Mr. BUSH: I will withdraw the words "damnatory character," and will say that the evidence was given with hostile feelings. Thirdly, (whether I am correct here, I must leave for you, Sir, and Mr. Bartrum to decide,) it is reported that Mr. Bartrum applied to you immediately after the trial, to know what proceedings ought to be instituted against Mr. Cox.

The PRESIDENT: You are asking questions again, you see, Mr. Bush, which makes our proceedings very dilatory. Mr. Bartrum did come to me and ask whether any proceedings ought to be taken by the Association in the matter. My answer to him was,—“I think it is a question between Mr. Cox and his patient, and I think the Association will only get into difficulties by taking up the question.”

Mr. BUSH: That is as I heard it. Fourthly, it is stated that Mr. Bartrum made efforts to turn Mr. Cox out of the Book Society. Fifthly, the special notice of the breathless silence which followed the reading of a paper by Mr. Cox, at a late meeting.

Mr. COLTHURST: I am accountable for that report. The Bath Secretary is not responsible for any report of the proceedings of the branch at Bristol.

Mr. BUSH: Sixthly. (This charge we did not catch.) And, seventhly, the garbled report of the last meeting, which appeared in the last *Journal*. I think every gentleman present must admit that that was a garbled report. Dr. Budd and Mr. Coe must admit it; and I—

Mr. AUSTIN, (shorthand writer): Sir, I must beg permission to be heard in reference to this charge.

Mr. J. BARRETT: Order, order. The reporter cannot be heard. No person who is not a member has a right to address the meeting.

Mr. AUSTIN: Sir, a charge having been made against the report of the proceedings of the last meeting, which I furnished, I ask permission, (not as a right,) to offer an explanation, and unless that permission is granted, I shall close my book, and decline to take any further note of the proceedings of this meeting.

The PRESIDENT: I think that, out of courtesy, we ought to hear the reporter.

The majority of the meeting concurring in the view taken by the President.

Mr. AUSTIN stated, that he attended the last meeting at the request of Mr. Colthurst, Secretary of the

Bristol Branch. His instructions were, not to take a verbatim note of the proceedings, although he had done so, but simply to supply a report for publication in the journal of the Association. Acting upon those instructions, and exercising the usual discretion of a newspaper reporter, he had transcribed so much of his notes as had appeared in print. The long list of speeches which had been read by Mr. Colthurst as being omitted, appeared to him (Mr. A.) to be unnecessary to a faithful outline of what transpired. The speech of Mr. Estlin, who brought the question before the meeting, was given at length, Mr. Cox's defence verbatim, and also the speeches of Dr. Symonds and Dr. Budd; unless, therefore, it was shown that anything was omitted from the addresses which *was* said, or anything inserted which was *not* said, he protested against the application of the term "garbled" to that report, the veracity of which he was prepared to substantiate by affidavit, if necessary.

Some discussion ensued, of which we are informed by the shorthand writer that he took no note, from the reasons indicated above. Eventually,

Dr. SYMONDS, (Bristol), rose and said: Sir, to bring this matter to an issue, I beg to move, "That the report of the last meeting, which appears in the *Journal*, be considered as accepted by this meeting."

Mr. COE: I beg to second that proposition, and I do so for this reason,—I do not agree with what has fallen from Mr. Bush, and the explanation which has been offered by Mr. Austin is so full, as to carry the conviction of truth upon the face of it. I confess, Sir, that at first I was somewhat grieved to find that I was not mentioned in the report as having supported the views of Dr. Budd, but after what I have heard I am perfectly satisfied, and I feel happy in seconding Dr. Symonds's resolution.

Mr. GREEN, (Bristol): I wish to say that I consider the report as fair and accurate as it could possibly be; it is characterised by fairness from beginning to end, and therefore the statement that it is a "garbled" report, is untrue. I think the statement that we have heard from the reporter, shows that he only used the general judgment displayed by reporters in such matters, and that it completely absolves both the Secretaries and himself from all blame in the matter. (Hear, hear.)

The PRESIDENT: I will put the question,—“That the report of the last meeting which appears in the *Journal* be accepted by this meeting.”

Mr. JOHN BARRETT: I certainly object to that.

The PRESIDENT: Do you wish to speak upon it?

Mr. BARRETT: I certainly do. When I find the speech omitted of the oldest surgeon, I believe, in this neighbourhood, who occupies the chair of our branch, and who has filled the Presidential Chair of the Association, I ask,—Is the omission of that speech to be considered as giving a fair character to that report? I do not mean to say that all that was said ought to have been put in, but I do say that this and other omissions ought to have been supplied. On the question as to the evidence, I think that the remarks of Dr. Davies ought to have been entered; the remarks of Mr. Godfrey also

ought to have been entered; and, therefore, I cannot consent to accept this report. I know several gentlemen besides myself who do not consider this to be a fair report. I do not mean to say that there have been any intentional omissions, but I would rather say that the omission of several very important things takes away from it the character of being a sufficient and correct report. And I must claim on principle that we should not give the sanction of the Association to a reporter from this or that quarter who decides for himself what he will omit and what he will insert. I must say that I think the Secretaries ought to have looked through that report, and where they found that important omissions had been made, they should have seen that those omissions were supplied. I have no wish to attribute anything like neglect to Mr. Colthurst, but I think he was a little napping at his post as he did not go through the report to see if there were any omissions. If he had done so it would have been far better, but, as he did not, I cannot agree to consider the report a correct one. As to Mr. Coe's speech, which was omitted, we would not allow Mr. Field to be heard; and, as Mr. Coe was the mouthpiece of Mr. Field, common justice required that Mr. Field's remarks (for they were his, *de facto*) should have been given. I say, then, that the remarks of Mr. Coe it would only have been justice to Mr. Field to insert, and as they were omitted, I cannot allow this to be a correct report. I do not wish to pursue the matter, but I object to the adoption of Dr. Symonds's resolution.

Dr. BUDD (Bristol): Sir, there are very important considerations involved in the question now before us. It is this, whether the report under discussion has been tampered with, or has it been garbled? Is it a tampered and garbled report, or is it a fair newspaper report given without bias? Is it one or the other? I hope, Sir, after what has transpired, that the insinuation which has been thrown out [that this report has been tampered with, will be withdrawn, and that we shall adopt it unanimously as a fair and impartial, if not a verbatim, report of all that took place. The fact that some of the strongest observations in support of the view which I took of Mr. Cox's case, which were made by Mr. Coe, were omitted, is of itself sufficient that there was no bias on the side of the parties opposed to Mr. Cox. There is no doubt, Sir, that the observations which you made as President are also omitted, nor is there any doubt that every thing which falls from you is entitled to consideration. Those omissions, however, we have heard were made at the discretion of the reporter; and that is a very different thing from saying that the report has been tampered with, or that it has been garbled to prejudice Mr. Cox's case. I apprehend, Sir, that this is the view which this meeting will take of the matter, and I hope the reporter will publish his own speech on the point to show how complete and satisfactory was his explanation. (Applause.) And, in conclusion, I would recommend the friends of Mr. Cox, if they are really acting on his side, to let us hear no more of garbling and tampering, but to admit that it was a fair and honest report, without any kind of bias whatever.

Mr. BUSH: If I understood rightly at the last meeting, this report ought not to have been printed and published in our *Journal*. (Cries of "Question, question.")

Mr. JOHN BARRETT: Sir, I still object to this resolution.

Dr. BUDD: That it is a *bonâ fide* report?

Mr. BARRETT: Yes.

Dr. SYMONDS: Sir, I beg leave to move "that the report of the last meeting, October 27, presented to the *Journal* by the reporter specially appointed be accepted as an impartial report."

Mr. COE: I second that proposition.

The question was then put and carried with only two dissentients. (Messrs. Bush and Barrett.)

THE PRESIDENT: I think we are relieved from a good deal of difficulty by the reporter having taken upon himself the responsibility of the report. This will completely absolve the Secretaries from the charge of having had anything to do with it.

Mr. BUSH: There are one or two other subjects to which I wish to advert, not on my own account so much as on behalf of Mr. Cox. It is stated, Sir, that Mr. Bartrum has expressed his satisfaction at your speech at the last meeting not being reported; and further, as a proof that Mr. Cox is not mistaken in the feelings entertained towards him by Mr. Bartrum, he is informed that Mr. Bartrum made this strong remark at the Council meeting, namely, that he was prepared to prove that Mr. Cox's whole bill was a concoction. I wish to move as an amendment to the resolution which has been proposed,—“That this meeting regret that the Council have been prevented, by Mr. Cox's resignation, from arriving at a decision on his case. That they feel that Mr. Cox, labouring under the impression that the Council intended to examine fresh witnesses to give a verbal refutation of that evidence which was given on oath, and having had just ground of complaint and dissatisfaction at the garbled report of the last meeting”

THE PRESIDENT: You must strike out the words “garbled report,” after the resolution we have just passed.

Mr. BUSH: Yes, I will do that. I wish it to be understood that I do not wish to exculpate Mr. Cox from all blame. I feel that he has taken a hasty step, but I am afraid that there are others among us who, if they have not taken the same, have at least taken steps as hasty as that of Mr. Cox. That it was injudicious and indiscreet of Mr. Cox to arrest Bourn there can be no doubt; but when I heard, as I did, the medical witnesses one after the other, in a Court of justice, give their evidence in a manner which appeared to me so erroneous, I will not say false—but so erroneous—I did not hesitate to come forward as I do now.

THE PRESIDENT: I think Mr. Bush will see the propriety of withdrawing the terms which he has applied to the medical witnesses.

Dr. BUDD: I beg to say that the reporter is bound not to “garble” his report in this respect. (Laughter.)

Mr. BUSH: I was going on to say, Sir, that when I entered the Court I had not the slightest intention of

going into the witness-box ; but when I heard the medical men making such an erroneous impression on the Jury and the Court, I felt myself bound, as a professional brother of Mr. Cox, to give contrary testimony.

MR. BAGSHAWE : Sir, I rise to order. We had all this over at the last meeting, when Mr. Cox thanked Mr. Bush for the kindness he had done him.

THE PRESIDENT : But Mr. Bush is now speaking on his amendment, and of course we cannot adopt or reject it without hearing his reasons.

MR. BUSH : I will merely add, Sir, that I have now known Mr. Cox some sixteen years, and, as two of the medical witnesses stated who were examined against him at the trial, I believe him to be an honest man. Having known him as I have said, for sixteen years, I can say confidently that he is as straightforward and honest a man, in my opinion, as any member of the profession. But that he took a hasty step in this matter there can be no doubt, and I regret it most sincerely. I do trust that this Association will act leniently towards a member of the profession situated as Mr. Cox was, and the resolution I have drawn up does not exonerate him entirely from all blame. It merely states that, as Mr. Cox has resigned in consequence of additional witnesses being called, or being about to be called against him, as he supposed, and in consequence, as he also imagines, of a garbled report of the last meeting.

MR. BARRETT : Not a "garbled" report.

THE PRESIDENT : No ; I suppose you cannot call it so now.

MR. BUSH : I will say, "as he supposed," and that he felt it his duty under the circumstances to withdraw. I cannot, if I were placed in the same position as Mr. Cox, say whether I should have taken such a step or not ; but, believing as I did with Mr. Cox that the Council were determined to call additional witnesses, and believing also that the report was not a correct one, I certainly should have waited before consenting to have persons giving verbal evidence against me which might have been given on oath at the County Court. I do not know that I need say more in defence of Mr. Cox than I have done. I feel it is a very painful case, and one which I trust will not occur to any member of this Association. But I again call on you, from my personal knowledge of Mr. Cox's general good conduct—I call on you as members of the same profession, to act leniently towards him.

THE PRESIDENT (after a pause) : Does anyone second the amendment ? (Cries of "Read, read.") The Secretary cannot read it until it is seconded : but perhaps Mr. Bush will read it himself.

MR. BUSH : This is my amendment :—"That this meeting regret that the Council have been prevented by Mr. Cox's resignation from arriving at a decision on his case. That they felt that Mr. Cox, labouring under the impression that the Council intended to examine fresh witnesses to give a verbal refutation of that evidence which was given on oath, and having had just ground of complaint and dissatisfaction at the report of

the last meeting, and of its having been published in the journal of the Association, was justified in withdrawing from the Association. Under these circumstances the meeting feels that further proceedings are undesirable."

MR. COLTHURST : The second paragraph of that resolution states that Mr. Cox had "just ground of complaint and dissatisfaction at the report of the last meeting." Now, this meeting has already resolved, on the contrary, that that report be accepted as an impartial report ; and that being so, we can hardly affirm that Mr. Cox had any "just ground of complaint and dissatisfaction" with it.

MR. BUSH : I will put it "as he considered."

THE PRESIDENT : You had better do that as a matter of policy ; for you can hardly expect the meeting to adopt a resolution which would stultify itself.

MR. BUSH : Then, with your permission, Sir, I will add these words :—"that Mr. Cox "having considered that he had just ground of complaint and dissatisfaction," &c.

MR. ESTLIN (Bristol) : May I ask whether Mr. Bush means to do away with the reception of the report of the Council by his amendment, because that has not been stated by him in the course of the proceedings. Is that the object of the amendment ? because, if so, Mr. Bush should let us know that it is so meant.

MR. BUSH : Certainly ; that was my intention.

THE PRESIDENT : Then you intend that the report be omitted, and that this resolution be received instead. Does any one second this proposition ?

MR. JOHN BARRETT : Though I confess, Sir, that if I had time I should like to alter this motion, and make it more brief, I will second it as it stands. I have had to regret more than once, Sir, in Mr. Cox's life his doing an hasty act ; and in his dealing with the Association in reference to the present case, although I have to a certain extent taken his part, and may be supposed to be of his counsel, I must not be taken to be responsible for all that he has done. For instance, I do not think him justified in making the wholesale charges he has against the Council of the Association. I do not think that the Council had a right, *per fas et nefas*, or that they were prepared so to condemn him ; nor do I give him my counsel *per fas et nefas*. I have a far higher idea of the Council, and of the members of this Association than to suppose that they would band themselves together to put down a brother member. But I beg the branch to consider the circumstances under which he has been placed. I can readily understand that some minds, without setting out with a desire to do injustice, may from an excess of honourable feeling have had their opinions warped and their conduct a little misdirected, even although they started with the desire to do that only which was just and honourable. And, Sir, I know of no profession more liable to this kind of deviation than the medical profession. (Hear, hear.) Because it is more social, and acts perhaps a little more on impulse than any other. But while I should be the last man to bring, and while

I do repudiate any such charge, I do think that the course which was proposed to the Council ought not to have been adopted. We have already heard from you, Sir, that it was very doubtful whether the Council would have examined any witnesses at all; but it was a most dangerous course to suggest; and I do think it ought to have been remembered that even in the lowest courts of law, when men even of the most unblemished honour are examined, it is always considered necessary to impose upon them the responsibility of an oath.

The PRESIDENT: But we had no power to administer an oath, if witnesses had been called.

Mr. BARRETT: I was only showing the danger of dispensing with the ordinary checks, and therefore I was very much pleased to hear from you, Sir, that it was very doubtful whether the Council would have sanctioned the course which was proposed to be adopted. Mr. Cox, however, was under the impression that that course would be taken, and I found that impression was very strong upon him. I admit that I advised him, in case that course was adopted, then to resign; but I also stated to him, that before he took that course, he should be perfectly satisfied as to the views of the Council. Speaking as I am before men of honour, I may state, that before Mr. Cox went to the Council, he was hardly master of his own conduct. I do think he ought to have waited before handing in that letter, and if he found then that there was the danger to be apprehended to which I have alluded, then I had advised him to resign. So far, then, with regard to what I advised Mr. Cox; for that I am responsible, and I have no wish to shrink from the responsibility.

The President: Then you second the amendment?

Mr. BARRETT: Yes; but if I do not, I wish to ask whether Mr. Cox's letter will be published?

Mr. COLTHURST: Yes; it is an integral part of the report of the Council.

Mr. BARRETT: I confess I should be glad to see the report and Mr. Cox's letter withdrawn.

The PRESIDENT: That would be so, if your amendment is carried.

Mr. BARRETT: Then, if this amendment is carried, the letter and the report will be withdrawn?

The PRESIDENT: Yes. As to what took place before the Council, I must say I think Mr. Cox acted hastily in resigning, because he must have been present at all that transpired, and might have objected to any one who was called before us, if he thought proper. As far as I know, it was not proposed to call any evidence that would not have been admitted on the trial.

Mr. BARRETT made an observation, which we did not catch, to which—

The PRESIDENT replied—No: that would not have been hearsay evidence.

Mr. BARRETT: I must remark, that the plaintiff's barrister or attorney, at the trial, called all the witnesses that were thought necessary; but one witness who was present was not called, for reasons best known to themselves. I mention that fact in justification of my view of the matter. ("Question, question.") These are the reasons on which I support this amend-

ment; and I cannot do so without saying, that I think, if the course to which I have alluded had been adopted by the Council, Mr. Cox would have been perfectly justified in withdrawing.

The PRESIDENT having put the amendment, two hands were held up in its favour, and an overwhelming majority against. Mr. Norman continued,—It is lost. The original question is,—“That the report of the Council be received, and adopted.”

Mr. BAGSHAW: I am one of those, Sir, who on the last occasion conceived that we were not allowed to speak. There were five gentlemen examined as medical witnesses on the part of the plaintiff in the case *Bourn v. Cox*, leaving out Mr. Topp, who it seems is not a medical man. Of those five, three were non-members of the Association, and they received an invitation to attend the last meeting, but we understood that we were not allowed to speak; at least that was my impression, for I only paid my guinea to become a member of the Association on the morning of that day. Mr. Cox complains of being damned by the medical evidence, but he was attended here by Mr. Bush and Mr. Barrett, as his counsel; he has had the say of the public in the published report, and therefore at the Council meeting, supposing the statements of Mr. Cox had been undone by hearsay evidence, it would have been nothing more than we had taken from Mr. Cox. Take the case of Mr. Barter, who was stated by Mr. Cox to have offered to show Mr. Harries a case of coexistent gonorrhoea and syphilis. Mr. Harries denies that any such offer was made to him by Mr. Barter, and says that he should have been only too thankful to have witnessed the case. Again, it was stated that all the medical witnesses stated the impossibility of these diseases co-existing. I can state that this was not so. I was the fifth medical witness called, and I said I did not think bubo could have existed so recently as was stated, because there were no marks or traces of it; Mr. Cox, however, stated that there was bubo. I deny, Sir, that any one of the medical witnesses for the plaintiff gave it as his opinion that syphilis and gonorrhoea could not coexist. In this day's *Journal* appears the following letter, which has been sent by us, in reference to the charges urged against us by Mr. Cox. [Mr. Bagshaw here read the letter which appeared in the *Journal* of Nov. 24, page 623, and proceeded.] I think, Sir, that will give a reason why nothing was said by us on the last occasion. Three of us were non-members, and, as we have been taunted, we were mute; there were, therefore, only two out of the five left—namely, Messrs. Bartrum and Skeate, and out of delicacy those gentlemen neither spoke nor voted on the question. I have nothing more to say except this:—the name of Mr. Cousins has been brought up; and I repeat that, why he was not examined at the trial, although he could have given evidence of a very important fact, was that the barrister, Mr. Saunders, thought the case for the plaintiff was quite strong enough without him.

Dr. BUDD: I really think, Sir, we had better not go into the matter.

Mr. BAGSHAW: I will drop it if the meeting wishes

it; but I will just add, that besides Mr. Cousins, the only additional witness proposed to be called was, I believe, Mr. Gibbs, the plaintiff's attorney. He would have produced the young man's letter, containing his version of the case, which was just as good as Mr. Cox's, and I have it now in my pocket, and can show it, if it is desired.

The PRESIDENT: If the Council did not think it right to go into these matters after Mr. Cox's resignation, I think the Association is in the same state.

Mr. BAGSHAW: But Mr. Bush has been allowed to state his views of Mr. Cox's letter; Mr. Cox has got his former letter and his defence into the *Journal*, and the meeting here having heard a series of questions put to Mr. Bartrum, I ask, is it—

The PRESIDENT: You will see that Mr. Cousins's name has been mentioned, but neither in Court nor here has he come before us, and it is not right, therefore, to go into what he could have stated.

Mr. BAGSHAW: Mr. Cousins was withdrawn, as I have stated, simply because Mr. Saunders conceived the case strong enough without him. As to the Jury, three out of five have stated that they had made up their minds before the medical evidence came on; and as to the hearsay evidence of Mr. Barrett that a young man named Biggs had stated that Bourn had admitted to him that the bougie had been passed, there is a letter in this day's *Journal* denying that statement *in toto*.

Mr. GREEN: I wish to say a few words upon the question, having been one of those who, on the last occasion supported the amendment of Mr. Godfrey. My reason for doing so was this: the facts of the case appeared to me to be in the last degree dammatory to Mr. Cox; but there being some palliating features in his address which I thought could be more fully considered by the Council than by a public meeting, and willing to catch at anything which could save Mr. Cox from the imputations which rested on him, I was ready to take the course suggested by Mr. Godfrey. If I had been compelled to vote that night, even with all the palliating circumstances to which I have alluded, I must have decided against Mr. Cox; but I felt as jurors do who like time to consider whether there were any circumstances which should prevent the verdict given at the trial from being confirmed by the Association. I felt satisfied too, that the case would be fairly considered by the Council, especially when I heard the remarks which fell from you, Sir, which were far from condemnatory of Mr. Cox, and also the remarks of Dr. Davies. There were matters, I conceived, which might have removed the charge of fraud from Mr. Cox, and this I felt could be best done by a calm examination of all the facts by the Council. For instance, it seemed to me that it would be important to know from the books whether all the entries had been made at once, or whether they had been made day by day. I took a hasty view of them with Dr. O'Brien, and I can only say that my impression was not favourable to Mr. Cox; but I resolved to suspend my judgment, because, perhaps, the Council would be able to come to a more certain conclusion as to whether they were all made at

once or daily. There were other circumstances, such as the nature and length of the illness and the charges, all of which I imagined would be gone into; and I think the Secretaries were fully justified, Mr. Cox having denied or disputed the decision of the jury, in having every evidence ready to enable the Council to come to a just conclusion. In the language of the report, Sir, Mr. Cox has evaded the inquiry, or at least he has shrunk from it. It is of course impossible to say what course the inquiry might have taken, or how it might have terminated. All that remains for us now is to consider what we shall do. I think it would have been much better if Mr. Cox had come forward and met the case fairly. However, he has not done so, and we have to consider how far we shall adopt the report of the Council. I think we cannot hesitate to adopt it, as a duty which we owe to ourselves, and the profession, and the public. The matter is a public one, and I think we can take no other course than to adopt the resolutions of the Committee. The honour and the character of the profession are at stake; and it is necessary that we should show not only that we do not approve but that we repudiate practices of the description with which Mr. Cox has been charged. Our duty to ourselves and to the character of the profession requires, then, that we should repudiate Mr. Cox. He has withdrawn, and has thereby saved us from the painful necessity which would otherwise have been imposed upon us. Sir, I will say no more; I feel that this has been a very painful case, but I feel also that we have no other course than to adopt the report which has been presented by the Council.

Mr. BARTRUM: In the questions which have been put by Mr. Bush, Sir, it has been intimated that I have been actuated by personal hostility in the proceedings which have been taken with reference to this case. Sir, I deny most distinctly that I have been actuated by any hostility with regard to Mr. Cox. With regard to my speaking to you, Sir, as to whether any proceedings should be taken by the Association, I conceive that if I had not done so I should not have fulfilled my duty as one of the Secretaries of this branch. I went to you in the simplest way, and having heard your opinion, I took no further steps, except to write to the Bristol Secretary, stating that unless some individual member brought the thing forward (using almost your own words to me, Sir,) it was not thought advisable that the Council or the Association should go into the matter. With regard to what has been said respecting the Book Society, I am as innocent as possible of any hostility towards Mr. Cox. The matter was forced upon me by three members of that Book Society; and I had nothing more to do with it, except in my official position. It did not originate with me, but was forced upon me by one of the oldest and best known members of the profession, who said to me,—“Bartrum, if the subject is not brought forward, we, as a body, shall throw up all connexion with the Society.” This is all I have to say; but I again deny that I have felt any hostility towards Mr. Cox, or any other human being.

Dr. TUNSTALL: I happened to have been subpoenaed

as a witness on the trial, and I rejoice that it was not thought necessary to call me into the box. Sitting as I did, however, upon the Bench during the trial, I can state that not one of the medical witnesses who were examined had any interview with the plaintiff or the solicitor, or knew what evidence they were expected to give. I have waited to state this, as I sat on the right hand of the Judge; and I can also state on my honour that he desired the Jury to dismiss the medical part of the case from their consideration, observing that great latitude must be given to certain expressions of opinion which had been offered, and recommending the Jury to look at the broad facts of the case, and not the evidence of the medical witnesses.

MR. J. BARRETT: I believe I have a right to speak on this motion. Mr. Bagshawe has referred to a paper in this day's *Journal*.

THE PRESIDENT: We are not discussing that, but the motion before us respecting the adoption of the report. You can answer any paper in the *Journal* in the next *Journal*.

MR. BARRETT: But Mr. Bagshawe was allowed—

MR. BAGSHAWE: No, I was stopped in it.

MR. BARRETT: I was going to correct Mr. Bagshawe in what he said several times about what I stated respecting a young man named Biggs.

THE PRESIDENT: We have been debating a long time on matters which appear to me to have nothing to do with the question before us, whether the report of the Council shall be received. If what you have to say has reference to that then I think you can speak; but if not, then I think you are out of order in going into the whole business over again.

MR. BARRETT: I merely wanted to explain.

THE PRESIDENT: Did Mr. Bagshawe mention your name?

* MR. BARRETT: Yes. Mr. Bagshawe referred to the report of the last meeting, in which there is something which I stated respecting Mr. Biggs, which Mr. Biggs denies in this day's *Journal*.

THE PRESIDENT: But we cannot have a discussion on the contents of the *Journal* here.

DR. BUDD: Sir, we have heard so much about the *Journal*, that I beg leave to move that Mr. Bartrum do read the *Journal* from beginning to end. (Laughter.)

MR. BARRETT: If that is carried, I shall move that Dr. Budd be requested to stop and listen to it. (Renewed laughter.)

THE PRESIDENT then put the motion adopting the report of the Council, which was carried with two dissentients only (Messrs. Bush and Barrett).

DR. SWAYNE'S MOTION.

MR. COLTHURST, Secretary, having read the notice of motion given by Dr. Swayne in reference to Mr. John Barrett's letter published in a public newspaper, respecting the case—*Bourn v. Cox*.

MR. BUSH rose and said: Mr. President, will you allow me to make one or two observations before Dr. Swayne commences?

THE PRESIDENT: Dr. Swayne is in possession of the meeting.

MR. BUSH: I think Dr. Swayne will not object to my occupying a few minutes. I object generally to the publication of letters on professional subjects in newspapers; but this, I conceive, to have been one of those cases in which it was justifiable to depart from that rule.

THE PRESIDENT: That is the very question we are about to discuss.

MR. BUSH: I feel, Sir, that I am equally responsible with Mr. Barrett in allowing this letter to appear in a public journal, as you will perceive from the last paragraph of the letter, in which Mr. Barrett says, "I am not writing anonymously; and my friend, Mr. Bush, who has seen this letter, allows me to say that he agrees with it."

MR. BARRETT: May I ask this question, Sir? Does Dr. Swayne intend to use these proceedings for the purpose of obtaining my expulsion or resignation from this Association? I am sure I may trust to Dr. Swayne's candour for an answer.

DR. SWAYNE: I have no hesitation in saying that I do not.

MR. GREEN: Dr. Swayne will leave the matter entirely to the meeting.

THE PRESIDENT: I understand Dr. Swayne does not intend to move any other resolution than the one of which he has given notice.

MR. BARRETT: I will explain why I have asked the question. If it were the intention to take any ulterior proceedings, I feel bound to say that I should not sit here while you went into a question which, by your own laws, ought to come before a general meeting.

DR. SWAYNE: Sir, my sole intention is to elicit the opinion of this branch on Mr. Barrett's letter, and not to found any ulterior proceedings. In bringing forward this case, it is hardly necessary for me to say that I am not actuated by any personal motives, as I am a perfect stranger to the gentleman whom it affects. I have been actuated throughout by a consideration of what is due to the honour of this Association, and the respectability of the profession at large. I have felt throughout that our proceedings with regard to Mr. Cox would be imperfect if they did not also take notice of a letter which appeared in the *Bath Journal* on the 11th of September last, bearing the signature of Mr. John Barrett.

MR. BARRETT: It is my letter.

DR. SWAYNE: That letter, Sir, was inserted as an advertisement; but I found upon inquiry from the Editor of the paper that it was so inserted without the knowledge of Mr. Barrett, and that the expense of the advertisement was paid for by Mr. Cox. I lay no stress upon this point, however. It is not the manner but the matter of that letter of which I complain. I say, Sir, that the matter is to the last degree unprofessional; and I have no doubt that this meeting will bear me out in that view. In order to prove this it is not necessary that I should read the letter at length, as I have no doubt you have all received a copy of it by

post. It is almost sufficient for my purpose to let it stand before you in its naked deformity, and to allow it to speak for itself. The charges against the writer are briefly these:—In the first place, it is considered as an illegitimate proceeding to appeal to the public upon a purely professional question, as this undoubtedly was, because the public is ignorant upon and incompetent to decide such points. But the principal charge is the gross indecency of giving publicity to the filthy and disgusting details which are here entered into with so much gusto. To the disgrace of our newspapers, publications of this kind are not uncommon; but they have hitherto been confined almost exclusively to quacks; the respectable part of the profession having most properly considered such cases as cases of secrecy. It is a new thing, however, to see a fellow of the Royal College of Surgeons who is not ashamed to put his signature to a production, compared with which some of the publications to which I have referred are pure, and to insert such a letter in a public newspaper which I suppose has access to some drawing-room tables, and therefore to some wives and daughters, who would thus have an opportunity of becoming acquainted with some loathsome questions of which every virtuous female ought to be ignorant. Let any man's daughter take up the paper, and what, I ask, can be the effect upon her mind of reading such statements as the following:—“Dr. Fenwick has reported 943 venereal cases, treated in the Lock wards connected with the Newcastle Infirmary. Of these not only were there 170 in which gonorrhoea and venereal sores were combined, but in a number of others there was a combination of gonorrhoea and secondary syphilitic symptoms.” And again:—“In the *Medical Gazette*, volume xv, page 193, will be found a case where gonorrhoea, ulcer, and bubo, in an advanced stage of suppuration coexisted—a combination which only wanted phimosis and stricture to be that described by Mr. Cox, except that there was happily no suppuration.” I do not know, Sir, that I need read all these other passages to show that this surely was a case of secrecy; but it may be said that all these statements and quotations would not be understood by non-professional people.

MR. BARRETT: It was intended to be understood by the non-professional public.

DR. SWAYNE: I thank Mr. Barrett for the admission, and will proceed to point out a part of his letter which leads me to another charge, which is, that Mr. Barrett has given currency to a charge of ignorance against another member of the profession. It is stated that one of the medical witnesses although he attended a patient for months was not aware of her pregnancy or her confinement. Now this appears to me calculated to do an injury to one at least if not to all the medical witnesses, for, although the name is not mentioned, we know the publicity which has been given to this trial, and we also know how apt ladies are to remember any error of diagnosis. I say then, generally, with respect to this letter, the profession having long and loudly demanded of editors of newspapers the exclusion of the filthy advertisements which are so common, it has

now become a question with what propriety we can do so, when one of our own members has himself contributed such a letter as that now before us. I think that letter calls for the strongest censure of this branch. I do not scrutinise the motives of the writer; I do not say that he was not actuated by a desire to help a man whom he believed to have been injured; but I repeat that his conduct calls for the strongest censure. And although I do not contemplate founding any ulterior proceedings upon the motion which I shall submit this evening, yet if Mr. Barrett should repeat such a course or attempt to justify it, then I think it ought to be taken into consideration whether he should continue a member of our Association; and if no one else takes up the subject I shall not be backward to propose it. My resolution, Sir, is this:—“That this meeting considers the publication of the letter in the *Bath Journal* of September 11, 1852, by Mr. John Barrett, on the subject of the trial—*Bourn v. Cox*, to be inconsistent with professional and moral propriety, and expresses its strongest censure of the proceeding.”

MR. A. PRICHARD (Bristol): I concur very much in what has fallen from Dr. Swayne.

MR. SMERDON (Clifton): Would not Dr. Swayne leave out the word “moral” from his resolution?

MR. PRICHARD: Certainly not; that is the pith of the matter. It was not only inconsistent with professional propriety to publish such a letter, but the moral tone of it is that of which I complain. The letter is a disgrace to us as a profession and as an Association, and it is a disgrace also to the College of Surgeons, of which the writer is a fellow. I heard however, in London the other day, that among the new-made fellows there are two, one of whom gets his living as a cheesemonger, and the other is a small tradesman.

MR. BARRETT: I am not a new-made fellow; I am a fellow by examination.

MR. PRICHARD: I am sorry to hear it. I merely referred to the other fellows as a matter of information, and to show that if any one wishes, or is ambitious of the honour, he has only to pay his ten guineas and he may be gratified. But, Sir, with reference to the matter before us, I should like to hear Mr. Barrett express some regret for the indecencies and the indiscretion of his letter. If that is so, we may allow the matter to pass over with the motion of Dr. Swayne, but if he attempts to defend his conduct by showing that others have done the same, then I should be disposed to take further steps, and I would say that Mr. Barrett ought to exfoliate with his friend, Mr. Cox.

MR. BARRETT: I think if that is to be so, that I shall not be present at a discussion, which will have to be renewed elsewhere. I ask Mr. Prichard whether he contemplates taking any ulterior steps?

MR. PRICHARD: I second the motion of Dr. Swayne and wait for what turns up.

MR. BARRETT: Well, then, I wish you good bye; because I think you will be trying a case before an inferior court which comes properly before the superior court.

THE PRESIDENT: There is no intention of doing so.

Mr. BARRETT: I am told so by Mr. Prichard.

Mr. GREEN: A good deal will depend on the course taken by Mr. Barrett. If that is satisfactory, there will be an end of the matter.

The PRESIDENT: Mr. Barrett must know that the branch cannot remove a member, that must be done by a general meeting of the Association.

Mr. BARRETT: Certainly, Sir; I am aware that there is a specific law as to the mode of getting rid of a member; but if it is contemplated to apply that law to me, in justice to myself I cannot allow the question to be mooted here, which will have to be mooted before a higher tribunal hereafter.

The PRESIDENT: This resolution goes to nothing of the kind; it must be an amendment upon this to take the course you are speaking of.

Dr. SWAYNE: I have not yet heard Mr. Barrett's defence, but I am prepared to say, that if this vote of censure is passed, and he should subsequently do anything to render it nugatory, I should then be ready to take further proceedings.

Mr. BARRETT: I understand that. Dr. Swayne answered me very clearly before.

Mr. COE: Sir, I rise to a point of order. Mr. Barrett has already spoken several times, but not to the question which is before us. I wish to know whether he is entitled to speak more than once, and I shall stand entirely by your decision.

The PRESIDENT: If Mr. Barrett is on his defence, he must speak once, and no more.

Mr. BARRETT: I am not now defending myself.

The PRESIDENT: Then I think you must not go on.

Mr. COE: Mr. Barrett has no right to ask any questions.

Dr. SYMONDS: I think, Sir, I may venture to say that my feelings on this subject are shared in by the majority of the members of this Association. We are weary of these discussions on the honour of the Association and the character of Mr. Barrett; and if Mr. Barrett would rise, and at once admit that he regrets having published the letter, on these grounds:—that at the time he was moved by strong feelings on behalf of a friend, whom he conceived had not received fair treatment in a court of justice—that he would not otherwise have brought the subject before the public—and that, therefore, there was some slight excuse or palliation for the course he had taken; if, I say, he would admit this, and also that he regrets the manner in which that letter was drawn up, I think such an admission would be very much to his advantage, and would contribute very much also to the peace of the branch. (Hear, hear.)

Mr. BARRETT: I am very much obliged to Dr. Symonds for what he has said; it is exactly what I should have expected him to do in such a case. But I have something higher in view. I must not say that which, in the sight of God, I do not feel to be true; and for me to say, looking at all the circumstances coolly, calmly, and solemnly, I would not now have advised and acted as I did, I cannot—and whatever may be the consequences to me, I do not feel justified in making such an admission.

Mr. COLTHURST: The question which Mr. Barrett

has raised as to the ulterior steps, is answered by stating, that it is utterly impossible for us to come to a final decision on the matter. Any further steps must be taken before that higher tribunal to which Mr. Barrett has adverted; and whatever views the proposer and seconder may entertain beyond the motion now before us, can only be carried out before that higher tribunal to which Mr. Barrett seems to wish to go.

The PRESIDENT, (after a pause): As no gentleman appears to wish to speak, Mr. Barrett, will you now enter on your defence?

Mr. BARRETT: If I understand Dr. Swayne and Mr. Prichard, they disclaim all intention of taking any further proceedings?

The PRESIDENT: Here is the motion; the proposer and seconder can do nothing more than that. I think you have nothing whatever but this resolution to deal with.

Mr. BARRETT: I have been considering whether it is an attempt to open a case here which ought to come before the general body.

Mr. PRICHARD: As far as I am concerned I shall attempt nothing of the kind; I go by what Dr. Swayne has stated.

Mr. BARRETT: That is all I ask, then.

The PRESIDENT having again read the resolution moved by Dr. Swayne,

Mr. BARRETT said: I beg the meeting to understand that I have had no wish to raise needless objections, but there seems to have been a little misunderstanding between Mr. Prichard and myself. So far from throwing obstacles in the way of the expression of the opinions of this Association, it is far from my wish; because, having acted as I feel with the desire to do what is right, I have no desire to flinch from an investigation of what I have done. That, Sir, is the feeling in my own mind, and it is also the feeling of my friend Mr. W. Bush; but I still protest against the course which has been taken by Dr. Swayne on the present occasion, because it involves a question, the consideration of which was not originally contemplated by this Association. When I entered this Association, I entered it on certain distinct understandings, and one of them was, that its objects did not include the consideration of medico-ethical questions. This is not stated in the list of the objects of the Association; and though I am quite ready to allow, that when the question is asked,—Whether a member ought, or not, to be expelled the Association, they would then have a right to consider every circumstance in relation to his conduct, and as this was the reason why I wished Dr. Swayne to answer my question as to his intention of instituting ulterior proceedings, I say that, as he has stated he has no such intention, you have no right to pursue the subject. The question before you is a question of medical ethics, and I contend that this Association has not provided for the consideration of such subjects.

Mr. COLTHURST: Here is a rule of this Branch, which provides for the consideration of, "all subjects connected with medical science or the welfare of the profession," and surely this case comes under the term "the welfare of the profession."

Mr. BARRETT: I am perfectly aware of that law; but I contend that the subject of medico-ethics was not

contemplated by the Association when it was founded. The objects of the Association are set forth in five clauses, and the fifth is "The maintenance of the honour and respectability of the profession generally in the provinces." (Loud cries of "Hear, hear.") Now how is that object to be carried out? It is stated how? "By promoting friendly intercourse and free communication of its members, and by establishing among them the harmony and good feeling which ought ever to characterize a liberal profession." I say, then, that medico-ethics have nothing whatever to do with the objects of this Association. There has been an attempt made lately in this city, I understand, to establish a Medico-Ethical Society. I heard it from a gentleman who is a member of the Council, and he mentioned the names of a number of others who were prepared to join it. He had himself declined to join the Society, but I need not state his reasons for so doing. Now if it were the case, that this branch had contemplated the consideration of such questions, it would be a work of supererogation to establish a Society to discuss questions which had been already provided for by this branch. But this is not so. I find that at Manchester also there is a Medico-Ethical Society, and a number of our own Associates belong to it. But we have no code of medico-ethics, and yet we have been many years in existence, and, as it seems to me, we should certainly have framed such a code if we had contemplated it among our objects. Now, I will at once allow what I believe has been stated on a former occasion, that there was a Committee appointed four years ago at Worcester, and that Sir Charles Hastings, when that Committee was appointed, quoted this fifth object of the Association in support of its establishment. But what has that Committee done? It has sat something like three or four years, and it has reported from time to time that it had no report to make; and at last, I believe, there was a report presented at Oxford, stating that the Committee could not agree upon the subjects which had been referred to it, so that we are just as far off now as when that Committee began its labours. I think the appointment of that Committee was a mistake on the part of Sir Charles Hastings; but, however that may be, you are entering on a question of medico-ethics, and on a judicial investigation, having no defined principles to guide you, and yet you are about to try a man for an act he has already done. That is, you are about to lay down an *ex post facto* law, contrary to all the principles of justice. There was an instance of this kind in the last century, where, upon the application of this principle, a man was hung; but I have always heard that proceeding referred to as the foulest stigma upon English justice. I think that it will be so with you to-night, and that you will be establishing the principle in this Association upon which that man was tried and hung. I protest, therefore, against the introduction of such a principle, which carries with it neither the recommendation of law or justice. But, Sir, I say more; I say that the subject of medico-ethics has been shunned by this Association, and I say that the practice of this branch shows that it has been shunned. It will be remembered that a Committee was appointed to consider the subject of homoeopathy, and that a report was presented which placed

under the ban of the Association all members who took part in that heresy. I am not going to deny that this Committee—(cries of "Question, question?"). This is the question—

Dr. O'BRIEN: Is it not competent to this meeting to have a question of fact laid before it? We are not contemplating legislation for any individual, and therefore I do not think all this discussion is necessary.

Mr. BARRETT: I think differently. There is an attempt made to pass a censure upon me; and I say that the Association has also placed under its ban certain gentlemen connected with homoeopathy. I was informed that two meetings ago application was made with respect to a gentleman in that very respect.

Mr. COLTHURST: I beg to say that no application of the sort was made to me.

Mr. BARRETT: I would ask the gentleman who just now interrupted me whether this is not so. Has there been any application of the sort made?

Dr. O'BRIEN: Not by me, or to my knowledge.

Mr. BARRETT: Well, then, it is a mistake. I must, however, go on to show that this Association has shrunk from these questions; and whatever feelings may be expressed on this subject, I am not responsible for them. I have a right to claim that the original principles on which I joined the Association should be applied to me. Sir, I am not responsible for any unpleasantness which may arise from this kind of discussion. I have been attacked, and am merely defending myself. A year or two ago a work was published on the Bath waters. That work was reviewed in our own *Journal*, and when that work was reviewed, the Editor, not content with praising it, proceeds to take a very large portion of the members of the Association to task, and to guide them in their future conduct. The passage must be fresh in your recollection, in which it was represented that our conduct was not that of honourable men; that the course taken for the patient was not often the best adapted for successful treatment; and that literally the towns referred to had been actually thinned of visitors on account of the practice which was pursued. I will read the passage to which I refer, if you think it necessary. (Cries of "No, no.") But that is not all. Soon afterwards a similar statement appeared in the public papers—whether it was from the same hand or no I will not say—but there was a great likeness between the two productions; and in it the practitioners of Bath, Clifton, Cheltenham, Leamington, and other watering-places, were held up. I am told also—and if this is not correct the author can correct me—that copies were supplied to the booksellers for distribution of a printed review which appeared in the *Bath Journal*; but I can state this of my own knowledge, that I saw a gentleman at a railway station either with some buns or stationery wrapped up in one of those printed reviews.

The PRESIDENT: This Association had nothing to do with that matter, Mr. Barrett, and could not take it up.

Mr. BARRETT: Why not, Sir? We have been told that the Editorial remarks in the *Journal* have been the means of bringing Mr. Cox's case before us. Mr. Estlin said, when he brought the matter forward, that he was moved to do so by the remarks in the *Journal*;

and that was what made me ask whether those articles had the sanction of the Association. Mr. Estlin stated, and it has been stated again and again, that it was owing entirely to the article in the *Journal* that Mr. Cox's case has been gone into; but, Sir, I do not remember that when this sweeping charge was made against the general practitioners, to which I have referred, that any steps were taken either by the Council or the branches to investigate its truth.

The PRESIDENT: I think there is a great difference between the two cases. You are speaking of an anonymous publication; we are considering a letter which you admit to be yours.

Mr. BARRETT made an observation which did not reach us.

Mr. GREEN: Sir, I rise to order—

Dr. TUNSTALL: I must say that this has been a standing sore between Mr. Barrett and myself for the last two years. He has been constantly hanging this charge over my head as the author of the book in question; but I declare that I did not know for twelve months who was the author of the review complained of.

Mr. BARRETT: I have not said that you did.

Dr. TUNSTALL: You have insinuated that the author of the review was present.

Dr. O'BRIEN: This has nothing whatever to do with the question before us.

Mr. GREEN: I think Mr. Barrett should be called on to speak to the question.

Mr. BARRETT: Have I not a right to protest against the step which has been taken by Dr. Swayne?

The PRESIDENT: Certainly you have, and to show that we have no right to pass the vote of censure which he has proposed; but I am afraid that you are leaving the most essential parts of your case, to which, as a matter of policy, I should have thought you would have addressed yourself.

Mr. BARRETT: If, when a man is charged with indecency—

Mr. COLTHURST: Sir, I rise to support the resolution on a point of order. In the seventeenth volume of the "Transactions" of the Association I find the following among the rules:—"That if any member be accused of professional impropriety or misconduct." Now this shows that it is perfectly open to us to consider such a question as that now before us.

Mr. BARRETT: Go on: read the whole rule.

Mr. COLTHURST: I will when I am not interrupted. This rule shows that it is open to us to consider any question of "professional impropriety or misconduct," and that is the point on which I rise. Mr. Barrett has occupied considerable time in endeavouring to show that we have no such power; but I would refer to the case of Mr. Edwards, of Wiveliscombe, in which the question was one of professional impropriety, and where the individual was requested to resign, as showing not only that we have the power, but that it has been exercised.

Dr. TUNSTALL: Mr. Edwards was expelled at the instance of the West Somerset and Taunton Branch, and I was present on the occasion.

Mr. COLTHURST: I refer to this rule merely to show that the remarks of Mr. Barrett are irrelevant to the question under discussion.

Mr. BARRETT: The branch at Taunton sent up three questions to the general Association:—First, whether Mr. Blake was a member of the profession, another question which I forgot, and lastly, what advice they would give respecting Mr. Edwards, he having consulted with Mr. Blake, if it should turn out that Blake was not a member of the profession. The Council wrote to the branch requesting Mr. Edwards to resign, and the question was afterwards brought before the Association at large, according to the 22nd rule, which has been quoted by Mr. Colthurst. That rule, I contend, only applies to the Society at large; and this branch having no such power, I do not think this rule has any weight on the line of argument I take. I assume that this Association has so great a fear, or I will say dislike, and has so little ground for entering upon these questions, that they have never to my knowledge taken up the points in any decided way. I remember, however, that when Mr. Kilvert was prepared to bring forward some such question, Mr. Bartrum said that it could not be brought forward at this branch, and notice was given for bringing it forward at the annual meeting of the Association, which I believe was held in this city. At that time it cannot be supposed that the branch was indifferent to the honour of the profession, but it was then felt that the subject was not originally contemplated by the original constitution of the Association, and therefore,—

Mr. GREEN: With the view of taking the sense of the meeting on the subject, which has now been discussed at such length, I will move,—“That this meeting is perfectly competent to consider the resolution before it.”

Dr. TUNSTALL: I will second that.

The PRESIDENT then put Mr. Green's resolution, which was carried with two dissentients (Mr. Barrett and Mr. Bush,) adding, I think there can be no doubt whatever that this branch has the power to entertain the resolution before it.

Dr. DAVIES: I hope there will be no more interfering with Mr. Barrett in his defence.

The PRESIDENT: I hope not, too, but the object seems to be to bring him to it.

Mr. BARRETT: I think this is a subject.

A voice: Cut it short.

Mr. BARRETT: It is all very well to cry out—"Cut it short;" but—

The PRESIDENT: The resolution which the meeting has passed, has taken away any responsibility from me in the matter. I might have thought it necessary to interfere, but it has been already decided that the meeting is competent to deal with the question before it; that being so, we are quite ready to hear what you have to say in your defence.

Mr. BARRETT: Am I to go on?

The PRESIDENT: Yes; but you are not to argue against our right to consider your case. You must take that point as settled.

Mr. BARRETT: I do not admit the right for one moment.

The PRESIDENT: If you do not, I shall be obliged to put Dr. Swayne's resolution.

Mr. BARRETT: I cannot, of course, control the actions of this meetings; but surely I have a right to

show that the circumstances under which I joined this Association give it no such right as that claimed to be exercised, and if I am prevented—

MR. SODEN (Bath): I would call Mr. Barrett's attention to an expression which fell from him just now, from which I inferred that he admitted that in extreme cases we are a competent body to deal with them.

MR. BARRETT: Not this branch, but the Association at large.

MR. SODEN: Well, if that is so, we are competent, at all events, to report our opinion, upon the conduct of a member. There can be no medium in the case.

MR. BARRETT: I cannot help it; I differ from Mr. Soden. I contend that this Branch has no right to take up such a question as that now before it; and his view of the subject is by no means a sequitur of my proposition.

MR. COLLINS (Chew Magna): Sir, we have now been summoned here twice to consider this matter, and I do hope it will be settled this evening.

MR. COE: The case of Mr. Edwards, of Batheaston, has been brought forward in this branch; and though I will not say it was a similar case, it established the principle against which Mr. Barrett has been contending.

MR. BARRETT: I must speak on this. Mr. Coe, if he remembers the case of Mr. Edwards, will recollect that the mover brought it forward without having given notice; and it was because some charges had been made in the absence of Mr. Edwards that the matter was gone into.

THE PRESIDENT: It will bring this matter, so far, to a conclusion, Mr. Barrett, if I ask,—Do you or do you not admit the right of this meeting to consider your conduct?

MR. BARRETT: I do not admit it. I protest against it.

DR. TUNSTALL (*sotto voce*): What does it matter in a court of justice if a prisoner who is convicted objects to the Judge passing sentence on him?

MR. BARRETT (with excitement): What does the man mean? I advise him to take care what he says respecting me.

THE PRESIDENT: If you deny the right of the Association to consider your case, I must put the resolution which has been moved by Dr. Swayne, and seconded by Mr. Prichard. I understand you do not wish to make any further defence?

MR. BARRETT: No; but that I may not be misunderstood, I wish to make—(Cries of "Chair, chair.") I can understand that there are very strong reasons and motives not very creditable to those who object to my being heard. ("Order, order.")

THE PRESIDENT: Your defence may take any shape but a denial of the power of the branch to consider your case. We make allowances for your position; but it will not do for you to deny our power to consider your case, and with the exception of that point you can say anything you like to defend yourself.

MR. BARRETT: It comes to this; that I cannot acknowledge the propriety of the course which has been adopted here, and if this branch chooses to attack me I must enter on a public defence of myself. I shall then state why I could not admit a principle which I consider to be fraught with danger, why I objected to the course into which this Association is now being urged,

and why I cannot admit that I am responsible here for what I have done,

THE PRESIDENT then put Dr. Swayne's resolution, which was carried with one dissentient (Mr. Bush.)

MR. GREEN moved and Dr. SWAYNE seconded a vote of thanks to the President, who acknowledged the compliment, expressing his readiness at all times to serve the Association, and congratulating the members on the termination of the present proceedings.

MR. BARRETT'S LETTER.

"To the Editor of the Bath Journal."

"Sir,—In this case, with Mr. W. Bush, I volunteered evidence in favour of the defendant. I stated in Court the motives which induced me to do so. I had heard reports to Mr. Cox's injury very indefatigably circulated before the trial which turned out to be false, and I may now add, that I heard given in Court medical evidence of a most damnable character against him, but the importance of which, in my estimation, was only equalled by its incorrectness.

"As a Surgeon I ventured flatly to deny the correctness of that evidence, and I request the favour of your allowing me to substantiate the justice of this denial.

"I do not feel it necessary to take into consideration Mr. Topp's medical evidence. He said he differed from Sir A. Cooper. Doubtless he does differ from him—not in opinion only. I confine myself to those gentlemen who profess not merely a diploma, but such an acknowledged professional reputation as makes it plainly a matter of justice to Mr. Cox to inquire how far, as men of science, they are borne out in the opinions they gave.

"The Judge thus states their opinions, 'As one witness after another was called, they all agreed that they did not believe that such a case ever existed, and was treated in this same way. Their evidence, the jury would see, took a duplex form: they did not believe that the diseases which were specified upon the face of the bill ever could exist in the same patient; and that supposing the effects, and nature, and symptoms, of the patient's case to be truly described, then they maintained that the treatment was incredible.' (*Vide Report.*)

"First, as to the co-existence of the two diseases. Mr. Lawrence, who is inferior to no surgeon of this or any other country, says of John Hunter:—'He was a great advocate for the identity of the poisons of gonorrhoea and syphilis; in fact, he says, the two poisons are the same,' and he details John Hunter's experiment to prove that the matter of gonorrhoea would produce the universally-recognised symptoms of syphilis. Mr. Lawrence denurs to this opinion, but he expressly says, 'Now we do sometimes find that gonorrhoea and syphilis exist together, but their co-existence is comparatively rare.' (Lawrence's Lectures on Surgery. *Medical Gazette*, vol. v., pp. 810, 811.)

"The experience of others, however, goes to show that their co-existence is more frequent. Dr. Fenwick has reported 943 venereal cases treated in the Lock Wards connected with the Newcastle Infirmary. Of

these not only were there 170 in which gonorrhœa and venereal sores were combined, but in a number of others there was a combination of gonorrhœa and secondary syphilitic symptoms. (*Medical Gazette*, vol. xliii., p. 737.)

"The idea of the impossibility of their co-existence seems not to have entered this gentleman's mind. He is considering whether mercury should or should not be employed in such cases and decides that it should be. This, it will be remembered, constituted an important part of Mr. Cox's treatment.

"In *Medical Gazette*, vol. xv., p. 193, will be found reported a case where gonorrhœa, ulcer, and bubo, in an advanced state of suppuration co-existed; a combination which only wanted phimosi and stricture to be that described by Mr. Cox, except that there was happily no suppuration. I think one of the medical witnesses stated that such a combination could not be cured in the time of Mr. Cox's treatment, but the case here reported was dismissed, cured, in less than five weeks.

"But, after all, the real question at issue was not whether a true syphilitic sore can co-exist with gonorrhœa. Such an inquiry would have had no interest for the Court whatever it might be for the profession. The question really was, whether a venereal sore of importance, which might or might not be true chancre, could coexist with discharge from the urethra, stricture, phimosi, and bubo. If it could not there was no alternative; Mr. Cox swore it did, and, therefore, he must have been guilty of perjury; if it could, then the medical witnesses, for the plaintiff, have done him deep if not irreparable injustice by their statement. To this issue, both he and they are tied down. That such a combination can exist I have already expressed my belief, and I would refer any one who doubts it to Mr. Skey's Lectures on the Venereal Disease. *Medical Gazette*, vol. xxiv., p. 263, where he is treating on what he calls 'the common primary venereal sore—the Venerola Vulgaris of Evans.' He states that these sores are often 'attendants on the latter stages of gonorrhœa,' (it will be remembered Mr. Cox's patient had been under treatment two months for gonorrhœa when he first saw him,) that they affect the prepuce (the case here where it caused phimosi); that this sore which he calls 'the primary syphilis of Mr. Wallace' (mark the term) is not attended with that kind of hardness which would leave behind it proofs of its existence, but is occasionally attended by more or less tumefaction or soft hardening (*i. e.*, it might have existed and yet not have left any traces of induration which Mr. Harries would discover, though it might have produced the phimosi which Mr. Cox swears it did; I have endeavoured fairly to represent Mr. Skey's opinions on this point); that it presents sometimes when situated on the prepuce a fungous appearance, which has gained it the name of the 'elevated ulcer' (Mr. Harries, when he examined the case, found what he called a wart, or, probably, a relic of this ulcer); that bubo is an occasional attendant on it (Mr. Cox said it was here); and, lastly, that this ulcer may be mistaken for true syphilitic sore.' These are the words of Mr. Skey:—'Some years since I was in consultation with an eminent surgeon on a case of venerola, occurring in an hospital patient, to which my attention was directed as to a case of the true Hunterian chancre.'

"I put it then to any man of common sense, whether Mr. Skey, who is a surgeon of eminence, in London, attached to St. Bartholomew's Hospital, may not be right, even though he be opposed to the strong opinion of the medical witnesses for the plaintiff, and if Mr. Skey be right then Mr. Cox may have seen such a combination of disease.

"The treatment, the Judge says, was maintained by the witnesses to be incredible, and particular exception was taken to the use of the medicated bougie. One point seems to have been forgotten by the medical witnesses, that it was a medicated bougie and that it was passed on that account. Mr. Cox's pupil imagined that the idea on which this practice was founded was original, but this is not the case. It has the sanction of the very high authority of Ricord; and so far from condemning the application of copaiba twice a day to the seat of the disease, if the treatment is to be successful, it should be done, if possible, repeatedly. I would refer those who wish for further information, on this subject, to Ricord's Lectures (*Provincial Medical Journal*, 1843, p. 227), and also to an interesting case reported in *Medical Gazette*, vol. xxxvi., p. 744.

"One medical witness considers poulticing and fomenting no part of a medical man's duties, but does he not remember that the great surgeon, whose pupil I think he was, the late Mr. Abernethy, thought so differently that when he lectured, not to pupils, but to the senior and leading surgeons of London, at the College of Surgeons, he described the right way of making a poultice. Another medical witness considered such things *infra dig.* in a surgeon, but surely he might have remembered that this was a case of secrecy, that these little operations could hardly have been done at home without discovery, and that certainly Mr. Cox would not have been allowed by his patient to have given his Mamma, Mrs. Betty Bourn, a lecture on the best way of making and applying a poultice to her son.

"Another gentleman could not believe a patient to walk without limping if he had such diseases—but strange, indeed, are the powers of concealment when character is at stake. I was once called to attend in her confinement a patient of this gentleman. She was then dying of consumption, and had, I was informed, been for some months of her pregnancy under his care. There were reasons why her real state should be concealed from him, and it was so concealed, for he never knew of her pregnancy, nor of her confinement, though attending her during the period of both. This was even more difficult to effect than walking without limping would have been in Mr. Cox's patient. And now, sir, I will leave this question to the public. When I gave my evidence for Mr. Cox I professed to do it from a sense of what was due to him and our common profession. I have no wish to say anything which may annoy any man, but when we come forward in a Court of justice and give an opinion we are responsible for it, and we have no right to complain if it be criticised.

"I am not writing anonymously; and my friend Mr. Bush, who has seen this letter, allows me to say that he agrees with it.

"I am, Sir, your obedient servant,

"JOHN BARRETT, F.R.C.S.

"13, Pierrepont Street, Sept. 9th, 1852."

"P.S. One remark more in justice to Mr. Cox. I have, since the trial, very carefully examined the entries in his day-book, at which exception was taken, and compared them with other parts of the same book. I am convinced that his best way of clearing himself of the charge of trickery with regard to them, is to let his book be as open to others as it was most readily allowed to be to me. The internal evidence of the *whole* book supports Mr. Cox's statement as to the manner in which these entries were made, and he has declared to me his readiness to submit them to such examination."

MIDLAND BRANCH.

THE general quarterly meeting of this Branch was held in the Board Room of the General Hospital, near Nottingham, on the 2nd inst. The chair was taken at three o'clock by Dr. WILLIAMS, of Nottingham, the President for the year; and amongst the members present were—Thos. Paget, Esq., Leicester; Drs. Heygate and Goode, Derby; B. W. Brown, Esq., Wymeswold; Dr. Smyth, Bingham; Dr. Somers, 8th Hussars; Dr. Gill, Dr. Ransom, Dr. H. Payne, B. Eddison, Esq., H. Taylor, Esq., J. C. L. Marsh, Esq., A. Darby, Esq., G. E. Stanger, Esq., Dr. Sloane, J. S. Alderson, Esq., T. L. Barwis, Esq., J. White, Esq., J. Orroch, Esq., &c.

Mr. Brown, of Wymeswold, read a very elaborate and highly interesting paper on "Intestinal Obstructions," an analysis of which we for the present postpone, in the hope that the valuable paper may itself shortly be published.

After an interesting discussion on some points brought forward by Mr. Brown, Mr. Paget moved, and Dr. Heygate seconded, a vote of thanks to the author of the paper.

Dr. Ransom, of Nottingham, made a communication on the "Comparative Value of several forms of the Galvanic Battery which have recently been used for Medical Purposes."

A discussion on the subject of Dr. Ransom's communication followed, in which Mr. Darby, Dr. Goode, and Mr. Stanger, took part. Dr. Goode moved, and Mr. H. Taylor seconded, a vote of thanks to Dr. Ransom.

Mr. Stanger communicated a "Case of Cystic Oxide Calculus," occurring in a farmer residing in the neighbourhood of Nottingham, and who had been labouring under symptoms of stone in the bladder for six months. The patient was about 50 years of age, and had long had delicate health. Having detected the existence of a stone, Mr. Stanger recommended him to have it crushed at once, as his constitution was beginning to sympathise with the local irritation. He was losing flesh, his appetite was capricious, and his rest often disturbed. The urine was generally turbid, with a quantity of mucous sediment; it had a slightly alkaline reaction. He was operated upon on November 13th; the stone was readily seized, and broken several times merely by the pressure of the thumb upon the instrument, (Brodie's lithotrite.) Very little pain was com-

plained of during the operation. On the following day he passed a quantity of fragments enclosed in a gelatinous semi-fluid mass. The whole came away at once, and was afterwards removed from the vessel entire. During the two following days the urine was bloody, and thick with mucus, but no calculous matter was voided after the expulsion of the above-mentioned mass. Neither had he from that time to the present any symptoms of the existence of stone, and none could be detected on sounding.

On analysis by Dr. Ransom, the stone was found to consist of a central mass of cystine, surrounded by crust, loose and crystalline in texture, and composed of a mixture of fusible calculus, uric acid, and animal matter.

After a discussion, in which Mr. Paget, Dr. Smyth, and Mr. Darby took part, Dr. Smyth moved, and Mr. Darby seconded, a vote of thanks to Mr. Stanger.

Mr. Marsh, of Nottingham, communicated two "Cases of Cataract, as illustrating the relative advantages of the operations for extraction and depression."

After observations by Mr. Paget, Mr. Brown, Dr. Ransom, and other members, a vote of thanks to Mr. Marsh was proposed by Mr. Brown, and seconded by Dr. Ransom.

The subject of medical ethics was introduced by Dr. Goode, of Derby, when, after remarks by Dr. Heygate, Mr. Paget, Mr. Brown, Mr. Stanger, and others, it was proposed by Mr. Eddison, and seconded by Dr. H. Payne,—“That the discussion of the subject of medical ethics be postponed to the next quarterly meeting.”

A vote of thanks to Dr. Williams for his able conduct in the chair, was afterwards proposed by Dr. Heygate, and seconded by Mr. Paget, and the meeting separated shortly after six o'clock.

EAST KENT & CANTERBURY MEDICAL SOCIETY.*

Cases Illustrative of some of the peculiar features of Hysteria.—By MR. RIGDEN.

A FEMALE, aged 19½ years, the unmarried daughter of a laundress, residing in the Military Road, Canterbury, has been the subject of the subjoined morbid phenomena for the last five years. At 14 years of age, when she seemed as healthy as other young females, the catamenia appeared, and recurred for three successive months, then ceased, and have never since returned. About this time she was suddenly attacked with severe pain in the right knee, without having received any injury or fright to account for it. Shortly afterwards an abscess formed in the cellular tissue above the knee, which was opened, and discharged abundantly. The abscess healed, but pain of the knee continued, and was soon felt in the other knee, and subsequently over the whole surface of the body. In two years from the

* Continued from page 618.

commencement of the illness, the lower limbs became contracted, as at present. During this whole period the alvine and renal secretions were regular, and sufficient. She was placed under the care of several practitioners (and also of quacks) until August, 1849. when she ceased to take medicine, or to use any remedial measures, and since that time she is *reported* to have abstained entirely from solid and fluid nourishment, except the smallest quantity of the pulp of an apple and of an orange.

Present general appearance.—The body is much emaciated, with slight oedema of the lower extremities, which are rigidly contracted, the thighs being completely flexed upon the abdomen, and the legs upon the thighs. There is exalted sensibility over the whole surface of the body. The pulse is accelerated and very feeble. The pulmonary and cardiac sounds are healthy. It is positively asserted by herself and friends that there has not been any evacuation by rectum or mouth for the last 18 months. The urinary secretion is very scanty, and is said not to exceed a table spoonful at a time, and to be only passed once in 10 days. An ulceration between the opposed surfaces of the calves and thighs, discharges freely.

Miss H., aged 35, unmarried, residing with her mother in Orchard Place, Canterbury, and possessed of an independance, is afflicted with exalted sensibility over the whole surface of the body, and with vomiting, which occurs from the least excitement; together with retention, or almost total repression, of urine. Until the 18th year of her age, from which period she dates the commencement of her ailments, she had enjoyed good health. She was then attacked with what she called "Cholera," and from that time to the present (seventeen years,) she has been daily afflicted with vomiting of a bland watery fluid, which is not invariably excited by taking food. The catamenia did not appear till the age of 30, but have been regular, though scanty, ever since. She has always been of a costive habit. At the age of about 31 years, or about three years and a half since, she first became unable to pass urine; a catheter was then introduced, but not more than a wineglassful of urine was withdrawn. Since this period she has never voided urine without the use of the catheter, which she introduces herself once in twenty-four or thirty-six hours, but rarely more than a wineglassful is withdrawn, and upon no occasion has more than twice that quantity passed at one time. Her bowels have never during this period acted without the use of warm-water enemata, which are administered not oftener than once in ten days. She is not subject to leucorrhœa, or any other morbid vaginal discharge, but imagines that her womb is prolapsed, which upon examination is not found to be the case. The perspiration, which has an urinous odour, is very excessive, particularly during the night. She has the appearance of a person in good health, and takes a moderate quantity of nourishment, but is quickly fatigued by exertion. She has always been subject to great anxiety, in consequence of legal disputes about her property.

A cold shower-bath, used daily, refreshes her, but produces no other benefit.

Miss H., aged about 17 years, unmarried, and residing in Orchard Place, Canterbury, with her mother, a lady of independent property, applied to Mr. Rigden in November, 1849, for the relief of an intermittant cough, which occurred regularly every day at 6 A.M., and 5 P.M., and continued with violence for a period of one to two hours. Her mother states that she has been so afflicted for several months, that at first it occurred but once daily, namely, at 5 P.M.; but since powerful remedies have been used the paroxysm has returned twice daily. In the intervals, she appears in as good health and spirits as other young females. She menstruates regularly, and in sufficient quantity, and the alvine and urinary secretions are regular. She has exalted sensibility in the region of the right hypochondrium, but nowhere else, and the application of a mustard plaister in this situation every morning, seemed to cut short the paroxysm of cough, but it had not the same effect in the evening: then the inhalation of chloroform had more influence than any other remedy. Electro-galvanism, purgatives, and various antispasmodics, gave no relief. The only cause that could be assigned for this curious affection was a severe punishment at school, which produced great depression of spirits, and was soon followed by the above-mentioned symptoms.

A female, aged 40, unmarried, living in North Lane, Canterbury, has been afflicted for the last 15 years with augmented sensibility over the whole surface of the body, particularly the neck and chest. She commenced menstruating at the age of 12, and has continued to do so regularly in sufficient quantity up to the present time. She dates her ailments from the age of 17, when she had scarlet fever, and at the same time, family misfortunes caused her great anxiety. She was, however, able to continue her usual occupation, being only troubled with occasional pain in her left side. At the age of 24 or 25 she lost her mother, which increased her distress, and since then she has never been able to leave her bed. About nine years since, she became almost blind for some months, there was, however, no apparent disease in the eyes; she afterwards gradually recovered her sight, and has retained it ever since. About the time that vision returned, she became affected with vomiting after taking any food, which invariably returned about a quarter of an hour after being swallowed, scarcely at all changed. The alvine evacuations were regular, though scantily tinged with bile. The urinary secretions were natural. Her diet for the last five years has been—tea or chocolate for breakfast, without solid food; at eleven A.M., half a pint of porter, and a piece of cake; for dinner, a mutton chop alone; at half-past four P.M., tea and bread and butter, and sometimes an egg; late in the evening another half pint of porter, which meal she occasionally retains. The antispasmodics that have been administered, have almost invariably been retained, except when taken about the time of her meals, when they have been rejected with the food.

Miss S., aged 22, unmarried, living with her mother at Tyler Hill, near Canterbury, applied December, 1850, for the relief of a severe pain in the left maxillary articulation, which was not increased by pressure. Motion of the part occasions a distinct grating sound, audible to other persons in the room. She states that she has been so afflicted for several months past, and has been under the care of several practitioners, without obtaining relief. The affection, apparently depending upon an hysterical state of the system, Tinct. Canth., with Tinct. Ferri Sesquichlor., was prescribed, and in ten days the symptoms were removed. It has been subsequently ascertained that this singular affection has returned.

The relation of the foregoing cases elicited many remarks, together with the details of several similar cases. The extraordinary self-delusion and deception that was practised upon others, frequently quite involuntarily, was particularly dwelt upon. The complete cessation of all alvine evacuations, and the almost entire abstinence from food during the eighteen months related in the first case, was not credited. An instance was mentioned, in which a young lady affected with hysteria was supposed, upon her own declaration, to be living absolutely upon nothing. However, when very narrowly watched, it was discovered that she subsisted upon a large basin of bread and milk, which was placed in her room at night, by her own request, for her companion lap-dog. A case was related, illustrating the want of self-control in checking these deceptions, which was sometimes experienced by the patient herself. A lady, of high moral character, became subject to hysteria, and had paralysis of one of her arms. After a time she recovered, and then, with much pain and distress, confessed that the paralysis had been feigned; and, although she was conscious during the whole period that she was very wrong, yet, at the same time, she felt an utter inability to prevent herself from continuing the deception. The great desire to excite sympathy and commiseration seemed often to be the actuating motive of these simulations in hysterical females, and when the patient became the object of charity, or the kind solicitude of friends and neighbours, the hope of recovery was almost removed. The control of mental influence seemed often to have more effect in bringing about recovery, in the more recent, or acute, than in the long continued forms of the disorder, and the influence of the ordinary remedies seemed to be efficacious in a similar degree. Several instances were quoted, in which strong mental emotion had effected a cure. The cases illustrated the point, that the exact relation between this disease and the menstrual function was not yet attained, and partook somewhat of the obscurity surrounding the nature of the complaint itself; in two of the instances, menstruation was natural, whilst in the other more or less derangement existed. Mr. Rigden mentioned that the application of the two remedies, which checked in some degree the periodic cough, was reversed, but the chloroform had no influence upon the morning attack.

Report on Small-Pox, as it occurred during three Epidemics in the practice of the Canterbury Dispensary between the years 1837 and 1848.—By Mr. RIGDEN.

The total number of cases attended during the three periods was 149.

During the first epidemic 48 cases were observed; of these, 30 were males and 18 females, 41 recovered, and 7 died. Those that died were of the respective ages of 5 weeks, 2, 3, 5, 6, 10, and 31 years. The proportion of deaths to the whole number attacked was as 1 to 7. The first case occurred Sept. 17th, 1837, and the last May 28, 1838; the attacks were thus distributed over the period:—

1	case occurred in	September
4	"	December
5	"	January
10	"	February
11	"	March
6	"	April
11	"	May.

The ages of those attacked varied from 5 weeks to 34 years, and the numbers of those attacked for each period of five years were:—

20	were	5	years and under.
15	between	5	years and 10 years.
6	"	10	" 15 "
3	"	15	" 20 "
0	"	20	" 25 "
1	"	25	" 30 "
3	"	30	" 35 "

Three cases only had been previously vaccinated, and were of the respective ages of 9 years, 11 years, and 39 years; they were all mild cases, and recovered.

There was no evidence to show how the first case contracted the disease. The second and third cases occurred at a variable distance from the first, though in the same district. The date of the three first cases noticed were—September 17th, December 4th, and December 26th.

In the second epidemic 33 cases were noticed; of these 20 were males and 13 females; 31 recovered, and two died. The ages of the two that died were 3 years and 5 years. The proportion of deaths to the number attacked was 1 to 16½. The first case applied August 6th, 1844, the last July 3rd, 1845; and the cases occurred thus:—

6	in August	4	in February
5	in September	6	in March
1	in October	2	in April
1	in November	3	in May
2	in December	1	in June
1	in January	1	in July.

The youngest was 7 months, and the oldest 13 years. The number attacked for successive periods of five years were:—

21	were	5	years and under.
10	between	5	and 10 years.
2	"	10	" 15 "

One case only had been previously vaccinated, a female aged 13; she had the disease mildly and recovered. There was no evidence to show how the

disease was imported. The first six cases all occurred in one lane (Black Griffin Lane).

In the *third* epidemic 67 cases applied; of these 39 were males and 28 females, 65 recovered, and two died; their ages being two years and eight years. The proportion of deaths to the number attacked was as 1 to 33½. The first case presented itself September 21, 1847, the last case May 14, 1848, and the entire number thus:—

1 in September	10 in February
6 in October	9 in March
12 in November	3 in April
10 in December	2 in May.
14 in January	

The age of the youngest attacked was three months, and the oldest 51 years.

18 were	5 years and under.
17 between	5 and 10 years.
15 "	10 and 15 "
5 "	15 and 20 "
1 "	20 and 25 "
7 "	25 and 30 "
1 "	30 and 35 "
2 "	35 and 40 "
1 was	51 years old.

Seventeen had been vaccinated, and in another case it was doubtful. Of these—

1 was 7 years.	1 was 28 years.
1 " 9 "	1 " 29 "
2 were 11 "	1 " 30 "
3 " 12 "	1 " 32 "
3 " 15 "	1 " 37 "
1 was 18 "	1 " 51 "

All these recovered.

The first case occurred in the person of a man, who resided in Wincheap, and who worked at the village of Chortham, where the disease then prevailed. The next case noticed occurred in the centre of the town, fourteen days afterwards. It appears that no case occurred after vaccination in a person under seven years of age, and thirteen of the twenty-one vaccinated were above the age of fifteen years. The most severe cases, and the greatest number, existed, generally speaking, in the districts most thickly populated by the lower orders, and most badly drained.

A Diseased Elbow-joint, which had been Removed by Amputation.—By Mr. J. REID.

The particulars of the case are briefly as follows:—

S. C., aged 20, a fair, delicate female, was admitted into the Canterbury Hospital March 7, 1851, with an abscess, which was situated behind and above the left olecranon, immediately beneath the integument, and which discharged matter by a narrow opening. The joint could be moved freely without pain, and was not, apparently, implicated. Just below, and on the inner side of this abscess, in a situation behind the inner condyle, there existed a soft fluctuating swelling, which was apparently quite distinct from the abscess. The abscess had commenced as a soft swelling, without obvious cause or marked pain, about six months previously, and had remained indolent till six weeks before her admission, when it enlarged, and was punctured. After she

entered the hospital, the opening in the abscess was enlarged, and she appeared to be doing well, until the second swelling became inflamed, suppurated, and ulcerated, when some thick matter escaped through the opening. A large fungous protrusion gradually presented itself at this opening, and the bare olecranon could be struck through it by a probe. The patient's health became affected; the pulse rose to 130 and 140, was feeble and wavy; night sweats set in, with loss of appetite; and a slight hacking cough, that had existed more or less for four years, became aggravated. The joint also became generally enlarged. The question of amputation was imperative; but, in consequence of the cough, it became necessary to examine the condition of the lungs as carefully as possible. On percussion anteriorly, the chest was *very* resonant below both clavicles, but dull for the space below the upper part of each mamma. Loud coarse inspiration was heard below each clavicle, the sound being uneven and divided, especially on the right side. The expiration was feeble and indistinct. The vocal resonance was much increased. The respiratory murmur was *very* faint below the mamma. In this situation, rhonchial sounds accompanied the inspiration, and were increased on deep inspiration, especially on the left side. Posteriorly, in the super-clavicular region, percussion was dull, and the respiratory murmur was less audible than natural, but the vocal resonance was increased. The percussion and auscultatory signs below the scapula, were the same as in front. From the physical signs, it was thought by the physicians who examined her, that tubercles existed. Amputation was performed, under the influence of chloroform, as the only chance that remained. For three or four days afterwards great constitutional irritation existed, the bowels were obstinately constipated, and there was constant vomiting, with the same high pulse that was observed before the operation. These symptoms yielded, the stump healed, and she eventually completely recovered, and lost her cough. She now, after an interval of one year and a half, remains quite well, and has become stouter than she was before.

The abscess first formed was situated in the integument covering the tendon of the triceps extensor cubiti, and had a doubtful communication with that secondly noticed; soft yellowish deposit in its neighbourhood, indicated it to have had a scrofulous origin. The second abscess apparently originated in the bursa between the tendon of the triceps and the olecranon, and was freely connected with the joint; the mass which protrudes from it was a growth from the exposed synovial membrane. In front of the joint, the synovial membrane was distended by a considerable collection of pus, and was thickened, soft, and vascular. Ulceration had commenced in the cartilage covering the head of the radius and the corresponding portion of the humerus.

The points commented upon as interesting in this case were—the apparent commencement of the disease on the outside of, and its subsequent extension into, the joints, and the risk under which amputation was performed, though happily terminating favourably.

Provincial Medical & Surgical Journal.

WEDNESDAY, DECEMBER 22, 1852.

THE influence of the "fourth estate" on the march of civilization—its good and evil effects upon the moral as well as the physical condition of man, are uppermost in the minds of most of our leading politicians, and will form an interesting object of inquiry for future historians. During the first half of the nineteenth century, the medical press may be said to have struggled out of chaos into existence; and another Sprengel, in writing its history, will have to take into account the influence of periodical medical literature on the progress of medicine both as an art and as a science, which has not yet been duly appreciated. The vigilant controul which it has exercised over the practitioners of the art, has been of great service to society, for though the rich have the power of protecting themselves—even if they do not exercise it—against neglect or mal-practice, yet, when the poor are concerned, what other protection can they find, but in the loud-toned voice of the medical press? With regard to the science of medicine, we believe that the vast improvements which have taken place throughout Europe and America during this period are mainly due to the same fostering hand. It has kindled in the minds of thousands a spirit of observation previously dormant, making every journal a valuable mine of facts and opinions, at the service of the master minds who have the time, the energy, and the genius to mould them into profitable shape. Nay, more, the medical press has been the parent of most of the standard works of the day, many of which their authors would have been afraid to publish, had it not been for the fostering dew of editorial praise. If such be the nature of a power which, to the best of our abilities we have wielded for the advantage of the profession, it may be worth while to glance at the present state of so potent an influence, to which, when these words see the light, we shall have ceased to belong.

In England, the medical press is now in a state of transition: most of its established organs are changing either their constitution, their form, or their Editors, whilst fresh journals are springing up in the place of others consigned

to oblivion. Out of courtesy, however, we will first glance at the sister kingdoms. In Dublin there is a quarterly journal, second to none in every valuable quality, and a bi-monthly one, which is edited with spirit, although the tenor of its recent remarks on English practitioners cannot be admired. In Edinburgh there are also two journals—a quarterly and a monthly. The former has become a bookseller's speculation, and now lives on its old reputation, and unless renovated by young blood, must speedily die a natural death. The latter is the property of MESSRS. CHRISTISON, SYME, SIMPSON, and BENNETT, and is certainly conducted with great energy and talent, but its most striking peculiarity is the loudness with which it echoes every month the praises of one or other of its proprietors, whilst at the same time its Editors lose no opportunity of bespattering with mud all other British medical journals, especially the hebdomadaries of London. In England, the most important arbiter in medical literature—the *British and Foreign Quarterly Review*, takes a new Editor, who intends to introduce original articles, an alteration to be regretted, as it will draft from other journals their most important contributions, without improving its peculiar characteristic of reviewing in a style and to an extent, which no other journal can aspire to. The *London Journal of Medicine*, a monthly periodical, dies for want of support, after a short career of profitless respectability. The *Medical Times* at one mouthful has swallowed up the *Gazette*, but like Pharaoh's lean kine, it does not seem to have grown the fatter. It, having used up one Editor, is now in the hands of a highly respectable gentleman, but he has received notice to quit, and another judge *in re medicâ* is said to be coming from beyond the seas.

A formidable rival to the old standards has sprung up of late, in the shape of the *Medical Circular*, which is a useful compilation from other journals, and has certainly its cheapness and pungency to recommend it. But towering above all still appears the *Lancet*—the *Times* of the profession, as verdant and sapful as when first started by its energetic Editor. Nevertheless the spirit of change has come over our own Association, or at least an active division of its light infantry, and this journal is henceforth to be so altered as to enter the lists in competition with it. Two weekly journals are absolutely necessary to ensure freedom of discussion, and

without that number we should in London share the fate of the profession in Edinburgh, where notoriously there is no free press. The *Medical Times*, backed by the staff of two old established journals, and by the influence of the chief medical publisher of the day, cannot do much more than pay its expenses, and is mainly kept in existence for other purposes than as a merely mercantile speculation. Will the new series of this journal be able to take the place of the *Medical Times*, and compete with the *Lancet* on the same terms, and with the same weapons? Time will show. Will our members be henceforth more willing than they have been, to enhance the value of their own journal by the results of their daily experience? We shall rejoice if such be the case, for we have henceforth a common interest with them in the success of our common property.

And now, one word for ourselves. We have brought the *Provincial Medical and Surgical Journal* to the termination of the first stage of its existence, and as it has hitherto been almost exclusively the organ of the members of the Association, it cannot be out of place to record our thanks for their support. We cannot view a change which renders necessary our severance from the *Journal* without regret. To feel otherwise would be to appreciate too lightly the honour done to us by the Association in confiding its important interests to our care; and we own our regret is increased by the fact of our having indulged the hope of carrying out by the aid of our friends, the most signal improvements in its composition and management. Henceforth, as a humble member of the Association, we fervently hope the change may realize the fondest wishes of those by whom it has been brought about, and that it may prove equally profitable to the Association, and creditable to the gentleman who will in future occupy the chair we now vacate.

Medical Intelligence.

CHANGES IN THE MANAGEMENT OF THE PARIS HOSPITALS.

L'Union Médicale mentions that the great facility for travelling has so encumbered the hospitals of Paris, that measures will now be taken to make the various departments pay for the people from the provinces who are admitted into the Paris hospitals. The Central Board, which was formerly instituted merely for examining and sending patients to the various hospitals, will now be transformed into a dispensary, without detriment to its former duties; so that the poor who

can be treated at their own residences may be attended to. It should not be forgotten that the municipal body of Paris contributes £350,000 to the expenses of hospitals.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 3rd instant:—George Arnison, Allendale, Northumberland; Philip Beal, Guernsey; Robert MacLiment, New York; Samuel William North, York; John Oliver Rouse, Great Torrington, Devon; Theodore William Rutter, Clapton; Edward Wilmhurst Tait, Heytesbury, Wiltshire; Thomas Wright, Kilkenny.

FELLOWSHIP.—The following members were admitted Fellows on the 9th instant:—Robert William Coe, Bristol, diploma dated April 26, 1844; James Godfrey, Bristol, October 4, 1836; Theophilus Caractacus Lewis, New Kent Road, August 28, 1842; Joseph Lister, Upton, Essex; Charles William Carrol Otway, Canterbury Row, Kennington, July 4, 1838; George Robert Skinner, Bath, January 22, 1847.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

The Central Council of the Association beg to call the attention of those members whose subscriptions are in arrear to the following resolutions passed at the Anniversary Meeting, held at HULL, on the 7th and 8th of August, 1850:—

“But if any Member's subscription remain unpaid twelve months after it shall become due, the *Medical and Surgical Journal*, and other publications of the Society, shall be withheld from such Member till his arrears be paid; and when any Member has been in arrears of subscription for the space of *three years*, application shall be made for the same by the General Secretary, and if the arrears be not paid in *three months*, the name of that Member shall be omitted from the list of Subscribers; but this omission shall not be deemed, either in honour or equity, as releasing any Gentleman from the subscriptions owing during his Membership.”

Those gentlemen who have not yet paid their subscriptions for the CURRENT YEAR, or who are in ARREARS, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association at Worcester.

All post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

J. P. SHEPPARD.

Worcester, October 23, 1852.

Secretary.

TO CORRESPONDENTS.

We have forwarded a paper from Cheltenham to Dr. Cornack, and also Dr. Ransom's communication, for which we regret that we could not find room. This is also the case with the report of the inauguration dinner of the Medical Benevolent College, sent by Mr. Propert.

INDEX FOR 1852.

A.

ABDOMEN, Enlargement of the, from Mesenteric Obstruction, 31
Abdominal Aorta, Ligature of the, 301
Abscess of Cerebellum, with Caries of the Petrous Bone, 54
